the interest of the public in genuine handiwork as distinct from the products of the machine was a further aim of the promoters. The scheme, started upon these lines, found ready support both among public bodies connected with art, commerce, and handicrafts, and private persons, who were prepared "to further in a practical way the education both of workers and of the public, and so to promote a purer taste and better appreciation of what is really good in the important branches of industry that connect themselves with art." The Board of Manufactures kindly granted the use of the Royal Scottish Academy Galleries, where the exhibition will be opened in the early part of the month of November. In accordance with the original scheme, the exhibition will be divided into two sections. In the first, craftsmen, whether professional or amateur, are asked to exhibit specimens of their skill, or to compete for prizes in various classes of work, including carving in wood, plaster, stone, and marble; painted decoration, the adornment of books and their covers, metal-work of different kinds, turnery, mosaic, and embroidery; while in the second a collection of artistic productions on loan will be brought together, supplying, as far as possible, "standard examples in the various special forms of work in which competitions are held." This loan collection, excellent materials for which have been kindly promised from various quarters, is also intended, by judicious arrangement, to afford in itself an instructive and beautiful exhibition. The rules provide that "originality of design will be considered in judging the merit of works submitted in competition," while "work submitted in competition must in every case be solely the work of the competitor," so it may be hoped that genuine craftsman's work, with some character and individuality about it, will be well represented in the Galleries. It is proposed to hold a short series of lectures in connection with the exhibition on subjects interesting to the public, but at the same time bearing on the practical life of the workman; and, should space allow, the operations of some of the simpler handicrafts may be illustrated by workmen engaged on the actual processes of modelling, carving, or chasing.

#### THE LATE JOHN FOWLER, C.E.

THE death is announced of Mr. John Fowler, C.E., at his residence, Preston-on-Tees, on the 11th inst., at the age of sixty-four, after a somewhat protracted illness, the deceased gentleman having, during the past few years, had to go through a number of painful operations. Mr. Fowler was a native of Aberdeen, having originally been a gardener. After spending some time in the South of England, he came to Tees-side, where his half-brother, Mr. James Johnston, was engineer to the Old Tees Navigation Company. In the year 1854 Mr. Johnston died, and Mr. Fowler, who for seven years had acted as assistant, was appointed engineer to the Tees Conservancy Commissioners. Since that time Mr. Fowler has held the position of chief engineer to the Commissioners till a few months since, when he was appointed consulting engineer. It has been under his direction that all the great works and improvements on the river Tees have been carried out, and the majority of them were conceived and originated by him. Mr. Fowler's knowledge was also requisitioned for the great river and canal undertakings in the kingdom. In connection with the Manchester Ship Canal, he gave evidence in its favour. For the improvements on the Ribble, too, he was also called in to express his opinion. As the engineer, he has tendered reports and executed many important undertakings in connection with the Ouse and Foss scheme. His last chief work was the construction of the new lock at Naburn. Mr. Fowler's son is now superintending the enlargement of the Castle Mills Bridge Lock.

#### Portland Stone in London.

SIR,—Mr. Francis Chambers commences his letter (*The Architect*, October 12) in reply to mine in the *Times* of October 1 (*The Monument*), with these words:—"The letter . . . contains statements so contrary to my experience . . . that I am induced to ask the insertion of a protest." I shall be glad to say a few words. In the first place, I think "the protest" a very weak one, for it should have been well supported by a few proofs rather than his own personal opinion. It is made in these words:—"I believe Portland stone to be the best build-

ing stone for use in London; it is less affected by the atmosphere than any other;" but he goes on to say, "It is dissolved or worn down very gradually and evenly," and further on he says that, in 1793, a painter applied the residuum of his pot to a stone, with the effect of preserving it, whereas the surface of surrounding stone, twenty-five years ago when he saw it, was reduced one-eighth of an inch. For my own part I have little doubt that the reduction during this twenty-five years has been going on at greatly accelerated speed, because it is in these modern days of immensely increased population and manufactories that the chemistry of the air has been so entirely changed as a destructive agent. In Wren's time London air was not much worse than that of a village; now it is highly charged with ammonia, nitric acid, sulphur, hydrochloric acid, carburetted hydrogen, carbonic acid, and many other gases; and in my letter I remarked:—"We might as well expect water and oil to mix as that limestone and hydrochloric acid . . . could live together harmlessly. Wren used the best material available in his day; but it cannot be doubted that, if living now, he would have rejected the Portland stone he used in favour of Craigleith—a carboniferous sandstone almost equal in durability to granite . . . or perhaps of granite itself, like the Duke of York's Column on Carlton House Terrace. These considerations seem to point out that it would be very undesirable to repair the Monument on Fish Street Hill with the perishable material of which it is built." And I am compelled to think so still, notwithstanding Mr. Chambers's "protest," and simply because Craigleith stone contains 98 per cent. of everlasting silica, and Portland 95 per cent. of perishable carbonate of lime.

But, further, I am at a loss to understand how, if Portland is "the best stone for use in London," so many other kinds have been introduced here during recent years. Very strong reasons must exist, for the Isle of Portland is only half the distance of these quarries, and has the economical advantage of cheap sea freight. In conclusion, I may admit that I admire Portland stone as much, perhaps, as Mr. Chambers, but I would not use it in the metropolis because it is exceedingly absorbent of moisture, and the acids I have referred to are solvent in rain, and, therefore, in due time find their way into the very heart of the stone of the exterior of buildings, causing disintegration by chemical action, and fractures by mechanical action during sudden changes of temperature in winter. I am inclined to think this last power greater than that of the iron clamps. As you are aware, Mr. Editor, my remedy for this mischief is the more general use in London of the igneous rocks, which are alike indestructible, beautiful, and economical, because they will never require costly restoration—of course combined with a style of architecture adapted to the nature of the material, which yet remains to be determined.—Yours truly,

HENRY TRAVIS.

#### CHURCH BUILDING AND RESTORATION.

**Kirkby Mallory.**—The ancient parish church of All Saints, Kirkby Mallory, near Hinckley, Leicestershire, was reopened after extensive repairs and additions on October 11. The date of the first church on this site is uncertain, but the existing building was erected in the thirteenth century, and now consists of nave, tower, and chancel. During the progress of the works several interesting discoveries were made. The plaster ceilings, put in probably at the end of the seventeenth century, having become decayed and dangerous had to be taken down, when the old roof principals and timbers were exposed. These have been carefully restored and made good as originally built. In building the new organ chamber and vestry, the arches and piers of an old chancel aisle were discovered built up in the wall. These have been opened, and form the communication between the organ chamber and chancel. It was also found that the walls of the nave contained on either side the arches and piers of an arcade, showing that originally the church comprised nave, aisles, chancel, chancel aisles, and tower, &c. The gallery at the west end has been removed, and the tower arch opened into the church. There are several interesting ancient monuments to members of the families of Byron, Noel, Clobbery, and others. The work of restoration will be continued as funds permit. Messrs. T. & H. Herbert, Leicester, were the builders, and Messrs. Osborn & Reading, of Birmingham, the architects.

**Upper Helmsley.**—The parish church of Upper Helmsley, near York, has been reopened, after having been rebuilt upon its old foundations. The alterations have been carried out in accordance with plans prepared by Mr. M. W. Lewis, of the firm of William Lewis & Son, architects, York. The original edifice was built in the ninth century, after the Norman style of architecture, and naturally had become decayed by the

ravages of time. In carrying out the work the architect has faithfully reproduced the Norman characteristics of the church. The exterior is of Breckon Hill stone, and the interior of stone from the Ancaster quarries, with Norman enrichments. The roof is slated with Westmoreland slates. The interior roofing, wood fittings and seats are of pitch pine. The floor is laid with marble mosaic in keeping with the date of the building, the mosaic work being richer in tracery at the east end.

### GENERAL.

**Mr. E. H. Dawson, A.R.I.B.A.**, of Lancaster, has been instructed to carry out his plans for new workshops at the Lancaster County Asylum, at a cost of about 4,000*l*.

**Mr. R. J. Richardson, C.E.**, read a paper on the Forth Bridge at the meeting of the Mason College Engineering Society, in Birmingham, last week.

**Canon Eyre**, vicar of St. Helens, has received from a resident in the town the money necessary to build a church, the erection of which will be commenced before long.

**Mr. G. H. Boughton, A.R.A.**, has returned from a sojourn in Norfolk, bringing back with him a number of studies to be worked out for the spring exhibitions.

**Mr. Alan Cole** on Tuesday evening gave a lecture at the Limerick Chamber of Commerce in support of a movement to revive the Irish lace industry, and suggested the establishment in Limerick of a school of art.

**Mr. P. Burne-Jones** is about to paint a small-scale portrait of Mr. Watts, R.A., as engaged on his large equestrian statue.

**Mr. P. H. Rathbone** will, on the evenings of November 7, 14 and 21, deliver a course of lectures on "Art, the Expression of a Nation's Character and Aspirations," in the Rotunda Hall, Liverpool.

**Mr. Fridgin Teale** will give a lecture at Northampton on "Sanitation" on Friday (to-day).

**The Statue of General Gordon**, by Mr. Hamo Thornycroft, A.R.A., was unveiled in Trafalgar Square on Tuesday.

**A Bazaar** in aid of the funds for the erection of the Victoria Art Galleries, Dundee, was closed on Saturday, after being opened four days. The total sum realised amounts to 4,748*l*.

**A Survey** is being made by Mr. Baldwin Latham for the extension of the water-supply at Bideford.

**The Carlisle School Board** have decided to build an infants' school for 300, and provision is to be made for the erection of a boys' and girls' department on the same site.

**A Memorial Painting** to the late vicar of Titchfield, representing *The Miraculous Draught of Fishes*, has been completed for the church by Mr. Alexander Fisher.

**Professor Ramsay**, of the Aberdeen University, is a candidate for the chair of classical archaeology in London, vacant by the resignation of Sir Charles Newton.

**A Portrait** of Charles Swain, the poet, by William Bradley, has been presented to the Manchester Art Gallery.

**A Bronze Statue of Shakespeare**, presented by Sir W. Knighton, president of the International Literary Association in Paris, was unveiled in that city this week.

**A Monument** of the late Monsignor Dupanloup, designed by M. Chapu, has just been inaugurated in Orleans Cathedral.

**At the Meeting** of the Manchester Literary Club last week a paper on "Lawrence, the Portrait-painter," was read by Mr. Richard Hooke.

**The Lord Mayor of Dublin** has requested the borough surveyor to prepare a report on the condition of dwelling-houses in Dublin, and on any measures required, either by amendment of the law or otherwise, to provide for the safety of life.

**The Free Library and Picture Gallery** which has been built from the designs of Mr. W. H. Lynn, in the Royal Avenue, Belfast, was formally opened on Saturday.

**An Exhibition** of pictures by the Aberdeen Artists' Society will be opened in the Corporation Art Gallery about Dec. 10.

**The West Riding Magistrates** on Monday awarded a second grant of 1,000*l*. as a present to Mr. J. Vickers Edwards, the West Riding surveyor, in consideration of important services in connection with the building of Menston Asylum.

**An Exhibition** of pictures, the best collection ever brought together in the town, it is said, has been opened in the Drill Hall, Basingstoke. A considerable number of the works are by students of Mr. H. Herkomer, A.R.A.

**A Technical Institute**, designed by Mr. Murray Robertson, and which has been built and endowed by funds bequeathed by the late Sir David Baxter, was formally opened on Monday.

**The Birmingham Art-circle Exhibition** was opened on Tuesday to the public. Fifty pictures have been brought together, but there are many of the members unrepresented, some few of them from illness or absence from England.

**A Carved Walnut Reredos and Altar** and wrought-iron sanctuary screens, executed from the designs of Messrs. Preston & Vaughan, of Manchester and Stockport, were unveiled on Sunday at All Saints Church, Heaton Norris.

**Bedworth Parish Church** has been handed over to Mr. J. Thompson, of Peterborough, for rebuilding. Messrs. Bodley & Garner are the architects for the restoration.

**The Committee of Art Classes** in Peterhead have decided to start advanced classes for higher instruction to students of drawing, painting, &c.

**The Prizes Awarded** in connection with a series of competitions in "vacation sketches" were presented by Lady King on Friday to the successful students of the Glasgow School of Art Club.

**A Paper** on "Glass Painting," a sketch of the history of the craft from the earliest down to the present time, was read by Mr. J. V. Rowlands at the last meeting of the Liverpool Art-Workers' Guild.

**The York Municipal Offices Committee** have recommended the construction of a Council Chamber at the Guildhall, with a gallery capable of accommodating a hundred persons, and to remove the police business to the new police premises in Clifford Street. It is estimated that this arrangement will save the city nearly 20,000*l*., by avoiding the erection of municipal buildings in another part of the city.

**Alterations** have been made at the celebrated Ship Hotel, Greenwich, of Whitebait Dinner renown, embracing the ventilation, which is now carried out on the Boyle system, the latest improved form of the self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

**The Hove Commissioners**, at their meeting on Saturday, passed a resolution in favour of carrying out, at the public cost, a new sea wall and esplanade at West Hove, in extension of what is locally known as the Medina "quarter deck." In connection with this it is proposed to erect extensive baths and club-room from the designs of Mr. P. B. Chambers, the engineering details being furnished by Messrs. Thomas Bradford & Co. We understand that it is largely due to the enterprising action of Mr. Alexander Hill, of the firm of Messrs. Tooth & Co., that this improvement has been secured for Hove.

**A Meeting of the Committee** of the Holland testimonial was held in Worcester on Saturday, when a letter from Mr. Oules, R.A., was read, stating he was unwilling to accept the commission which had been offered him in consequence of the death of Mr. Holland, but that he would be willing to help to choose an artist, and also aid him from his remembrance of Mr. Holland. It was decided to apply to Mr. Haynes Williams, and also suggested that the surplus money, after presentation to Mrs. Holland of the portrait, should be used for establishing Holland scholarships at the Victoria Institute.

**Mr. W. H. Cheadle**, of Stafford, was on Tuesday appointed county surveyor for Staffordshire. At the meeting of the county magistrates on the same occasion, Mr. Frank James pointed out that the county surveyor had not only to look after the county property, but was also the architect for the county, for which he received an independent commission. He thought it was not right that the personal interest of the county surveyor should be in some degree antagonistic to the county; and on his motion a resolution was passed approving of an alteration in the rules under which the county surveyor was appointed, and to which the newly-appointed surveyor would be subject, the further consideration of the matter being left to a committee.

**The Carpenters' Company** have, with the view of inducing candidates to do better practical work at the City and Guilds of London examinations, offered to purchase specimens of carpentry, should they be recommended by the examiner, and they have just purchased four models. The examiner, Mr. Banister Fletcher, F.R.I.B.A., in his report mentioned that usefulness of the models depends upon their practical size and the power of taking them to pieces so that the joints may be examined by the students. The Carpenters' Company have also opened a "Free Technical Lending Library" for the benefit of competitors for the above examinations, and for the more advanced examination of the Carpenters' Company.

CRIMINAL PROCEEDINGS, under the new Merchandise Act, will be instituted against any person falsely representing any form of ventilator to be a Self-acting Air-pump Ventilator, said title being registered and our Trade-Mark, applicable only to ventilators manufactured by us. Any infringement renders the person infringing liable to two years' imprisonment. ROBERT BOYLE & SON, Ltd.

*Special arrangement may be made for a series of insertions on application to the Publisher, P. A. GILBERT WOOD 175 Strand, London, W.C.*

### EDITORIAL NOTICES.

*The authors of signed articles and papers read in public must necessarily be held responsible for their contents.*

*No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.*

*Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.*

### TENDERS ETC.

As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 p.m. on Thursdays.

Correspondents, when writing to notify an extension of time, or an alteration of the date of sending in Competitions or Contracts, are requested in their letter of advice to write at the head of the required change—"Contract Reporter to THE ARCHITECT."

### NOTICE TO THE PUBLIC.

By the Post Office arrangements THE ARCHITECT can now be sent to any part of the United Kingdom by an affixed Halfpenny stamp; hitherto the postage has very frequently been twopence per copy. The Publishers will be happy to forward, for 20s. per annum, post paid, THE ARCHITECT, to residents in towns and neighbourhoods to which there is no easy access by railway. Terms for the half-year, 10s.

Our readers are invited to address us on subjects of interest to themselves or the public. We shall be always ready to insert letters asking for a solution of any suitable questions to a professional or practical nature, and to receive replies of such inquiries.

### CONTRACTS OPEN.

BELFAST.—Oct. 22.—For Construction of Lock for the Lagan Navigation Company. Messrs. S. & W. H. Stephens, 41 Donegall Place, Belfast.

BISHOP'S CASTLE.—Oct. 27.—For Construction of Water-works in the Borough. Mr. Aaron Hamar, Borough Surveyor, Bishop's Castle.

BISHOPWEARMOUTH.—Oct. 20.—For Erection of School Buildings at the Grange. Mr. T. W. Bryers, Clerk to the School Board, 15 John Street, Sunderland.

CAMBERWELL.—Oct. 31.—For Extension of Infirmary, Havil Street, for the Guardians. Mr. R. P. Whellock, Architect, 45 Finsbury Pavement, E.C.

CARDIFF.—Oct. 23.—For Restoration of Llancafarn Church Tower. Messrs. Seddon & Carter, Architects, 7 St. Mary Street, Cardiff.

COCKERMOUTH.—Oct. 24.—For Heightening Boundary Walls at Board School, Wyndham Row. Mr. John Musgrave, Clerk to the School Board, Cockermouth.

EAGLEY.—Oct. 25.—For Building Boundary Wall at Sewage Works and Retaining Wall to River Eagley. Mr. James Parkinson, Surveyor, 50 Station Road, Turton.

GLUSBURN.—Oct. 22.—For Building Stone Chimney (50 yards high), Hayfield Mills. Messrs. Petty & Ives, Architects, Halifax.

HARROGATE.—Oct. 23.—For Building Lecture Room, Chapelkeeper's House, Boundary Walls, &c. Messrs. Morley & Woodhouse, Architects, 269 Swan Arcade, Bradford.

HASWELL.—Oct. 27.—For Building Manager's House and Shop. Mr. H. Hind, Secretary, Co-operative Provision Society, Haswell.

HELSTON.—Oct. 20.—For Construction of Storage Reservoir at Tregathenan, and Laying Main Pipes (four miles). Mr. S. W. Jenkin, C.E., Liskeard.

LEEDS.—Oct. 29.—For Enlarging Board School. Mr. Lee, Clerk to the Board.

LIMERICK.—Oct. 25.—For Building Constabulary Barrack. Office of Public Works, Dublin.

RAMSEY.—Oct. 22.—For Construction of Sewage Outfall Works. Mr. J. Mansergh, Engineer, 3 Westminster Chambers, Victoria Street, Westminster.

SEASCALE.—Oct. 20.—For Building Two Dwelling-houses, Warehouse, Large Room, Stabling, and Coach-house. Messrs. J. Wrigley & Sons, Seascale.

STOKE-ON-TRENT.—Oct. 29.—For Alterations and Additions to Penkull Schools. Messrs. Scrivener & Sons, Architects, Howard Place, Hanley.

WEST BROMWICH.—Oct. 23.—For Laying Cast-iron and Earthenware Pipes with Manholes, Ventilators, &c. Mr. John T. Eayrs, Borough Engineer, Town Hall, West Bromwich.

WITHINGTON.—Oct. 26.—For Building Mortuary at Union Workhouse. Messrs. Mangnall & Littlewoods, Architects, 29 Brown Street, Manchester.

WORCESTER.—Oct. 31.—For Making Sewers and Works in connection. The City Surveyor, Guildhall, Worcester.

P. JOLIN &amp; CO., Narrow Wine St., Bristol.

## BANFIELD'S IMPROVED PATENT INDICATOR,

For Closets, Lavatories, Bath-Rooms, Offices, &amp;c.

Liberal Discount to the Trade.

## PRICES.

Lacquered Brass, 4/6; Bronzed Brass, 4/9; Nickel-plated, 6/; Japanned Iron Lock with Brass Indicator, 3/6.

This Lock supplies a want which has long been felt for a reliable and inexpensive means of showing when an apartment is engaged. By simply turning the handle, the door is locked and the word "Engaged" shown on the outside. Conversely, the act of unlocking withdraws the word from view. This Lock is a distinct improvement over all others; there are no wheels to clog, the working parts are covered, and it cannot fail to indicate accurately. It is very neat in appearance, the same of simplicity, and the cheapest contrivance of the kind yet introduced. It can be easily attached to doors of any thickness, or either hand. A loose key can be supplied at a small extra cost for opening the lock from the outside, an advantage possessed by no other Indicator. The principle can be applied to existing locks, either mortice or rim.

To be obtained of the Patentee, E. BANFIELD, BRIGHTON, Sussex, and of all Ironmongers.

## VOLUME XXXIX. OF THE ARCHITECT.

HANDSOMELY BOUND IN CLOTH, GILT LETTERED. Price 12s. 6d.

## TRADE NOTES.

THE American log-raft system is not a novelty on this side of the Atlantic. Last month a raft went down the Rhine from Mayence to Holland, which was 725 feet long and 170 feet broad. It carried a crew of 120 hands, housed in some dozen huts along the raft, and the timber was worth 20,000l.

THE Free Library buildings in Capel Street, Dublin, are being extended. The work is being carried out by Mr. James Kernan, contractor, of Talbot Street, Dublin.

NEW sewage outfall works have just been completed for Horwich by Messrs. Walkden, of Liverpool, on a site adjoining the Blackrod Station.

A PAMPHLET setting out the working of the Birmingham Corporation gas undertaking during the last twelve years has been prepared by Mr. Manton, who is a member of the Gas Committee. During that period alterations and extensions, some not yet completed, have been made. In 1875 the total capacity of the gasworks was per day 15,047,000; total capacity of the works in December 1887, 20,500,000; completion of purifying plant at Saltley, equal to retort and storage capacity, will add 1,500,000; and the filling up of the Windsor Street retorts 4,050,000; making a total productive power of 26,050,000.

The estimated capital expenditure required to provide for this increase during the next seven years is 45,000*l.*; a further estimated expenditure of 130,000*l.* will complete the Windsor Street Works, and will bring up the total production per day to 32,500,000. Thus, for an actual net expenditure of 293,409*l.*, and an estimated expenditure for completion of 175,000*l.*, making a total of 468,409*l.*, the department will be enabled to meet the requirements of the next twelve or fifteen years, at less than one-half of the amount which was expected to have been spent to the present date.

At the annual meeting of the Stourbridge School of Art on Friday evening it was stated that there were difficulties in the way of establishing a museum, and that Mr. C. E. Swindell, who had previously given money for the purpose, would allow his donation to be used in other ways for the benefit of the school. The foundation of a scholarship has been suggested.

OFFICIAL intimation was given last Friday by the makers of best iron thin stamping sheets, in South Staffordshire and East Worcestershire, of an advance in prices of 1*l.* per ton. An advance of 20*s.* is also declared on tinned sheets.

THE funicular railway station at Orvieto was opened last week. It ascends the hill for 540 yards, when it meets the high walls of the city, which it runs through by means of a tunnel 130 yards long, emerging at the highest altitude—240 yards above the level of the railway station. By the method adopted for obviating accidents, the ropes are subjected to a maximum strain of one-fifth of their resisting power. Between the metals a broad oak beam runs along the whole length of the line, firmly fixed to the sleepers, and the bottom of the carriage is provided with a steel beam armed with seventy-two spikes. The body of the carriage is held firmly in position by the wire and suitable levers, so that if the rope should break, the gravity of the carriage, which weighs over four tons, would fix the seventy-two spikes instantaneously in the oak beam, and the carriage would stop immediately.

ONE of the clock weights has done damage in Ecclesfield Church by falling from its place in the tower, a distance of about 50 feet, cutting a hole through the belfry, demolishing one of the choir stalls, and injuring two others. The weight is estimated at about a quarter of a ton.

MESSRS. KAYLL & Co., of Ellis Court, Aire Street, Leeds, have completed, for the Idle parish church, a stained-glass window as a memorial of the wife of the Rev. Henry Harrison, vicar. The subject chosen is Dorcas, who is represented dis-

persing her gifts to the poor. The presentation of a rich diaper fabric to a beggar, with widows and children, forms an effective group, having a background in the portals and trees of Tabitha's residence, and a view of the city beyond. The selection of Messrs. Kayll & Co. for the preparation of the window was the result of competition. The work is pictorially rather than conventionally treated. The figures have a roundness of modelling, and the draperies a warmth of tone, which contribute highly pleasing and satisfactory results. Dorcas is represented as a benevolent and matronly creature, but equal, if not greater, care has been bestowed upon the features of the suppliants for her benefactions.

THE stage of the Parc Theatre, Brussels, has recently been lighted by means of the Wenham "Safety" gas lamp, and we understand that the experiment is a complete success. This is an important move in the right direction, as the use of so many naked lights over the stage is, as everyone knows, a source of great danger, and, seeing that the Wenham lamp is entirely enclosed, this risk is overcome. The illuminating power of these lamps is very great, and at the same time the economy, as compared with ordinary burners, is very marked. These lamps have also recently been used at the Promenade Concerts, Covent Garden, with great success.

MR. R. SHACKLETON gave a lecture in Bradford on Monday evening on the waterworks question in relation to the ratepayers and the trade of the borough, and spoke in favour of using the waters at Grimwith until they were exhausted, and of then drawing the waters of the Nidd into Skyrholme and storing them there.

MESSRS. J. & G. THOMSON, at Clydebank, have nearly completed what are affirmed to be the largest shear legs in the world. The legs are of steel plates seven-eighths thick, closely rivetted, and strengthened in various ways. They are of enormous length, and weigh some 112 tons. The new crane will lift over 150 tons.

ON Tuesday Messrs. Bissett & Son, contractors, of Sheffield, handed over to the Birmingham Guardians the new workhouse infirmary, which they have erected under the direction of Mr. W. H. Ward, the architect. Mr. W. C. Bissett said he had given the work his closest attention, with the view to execute the contract in a manner that would meet with general approval. It had been a very great pleasure to him to be connected with the Building Committee, from whom he had received every consideration and assistance. He did not anticipate any

### IMPORTANT COMMUNICATION.—WHITELEY'S FIRE.

WILLIAM WHITELEY, Westbourne Grove, London: October 12, 1887.

HOBBS, HART & Co., Limited.

GENTLEMEN,—It affords me very much pleasure to express to you my satisfaction and admiration at the splendid fire-resisting powers of your Strong-room Doors and the Safes.

The recent fire at my establishment, in my opinion, subjected them to the greatest possible test, and through all they proved invulnerable. The contents of both Strong Rooms and Safes were entirely preserved, although the fire was of such intense destructive force.

You will be pleased to hear that it has been decided to adopt your Patent Clutch Rebated Doors for all the party walls in the new buildings now in course of erection.—I am, Gentlemen, faithfully yours,

(Signed) WILLIAM WHITELEY.

defects being found with his work as contractor, but whatever should arise he would—if it were not for years to come—make good the defects. There were still a few tradesmen engaged in the building in carrying out their respective contracts, but their duties would be soon completed. The contract with his firm was now terminated. The Chairman said the committee felt that Mr. Bissett had used very great exertions of late in pushing on the work, and particularly so as to be able to hand it over to the guardians that morning. He believed the contractors had done the guardians justice, and had carried out their work with great credit to themselves.

THE Leeds Town Council have sanctioned a proposal to purchase for 4,000l. an area of land containing 1,252 square yards in Harper Street, for the extension of Kirkgate Market.

THE report of the joint committees of the Town Councils of Edinburgh and Leith, on a general scheme for the purification of the Water of Leith from Balerno to the sea, includes the construction of a sewer from Balerno to Coltbridge to join the new Water of Leith sewer, which is to start from that point, and the construction of a compensating reservoir to make up for the water abstracted from the river. The cost of these and other suggested works would be 44,000l., which, added to the cost of the sewer from Coltbridge to the sea, would bring up the price of the joint scheme to 130,000l.

ON Thursday evening last week the Northampton master builders had their annual dinner. Mr. W. H. Smith, the president, was supported by Mr. Martin and Mr. Norman, members of the Town Council, and Mr. Gibbins, assistant borough surveyor, Mr. S. J. Newman, architect, and Mr. Ains, secretary. Mr. Martin, in proposing the health of the architects, said builders and architects sometimes disagreed, but as a rule the latter were very useful and a great help to the builder who wished to please his client. Many builders had been much aggravated when the client had tried to do without an architect, and when the work was half done had been dissatisfied with it. The builder then had no third party to rely upon. Other toasts were proposed, and among them success to the Northampton Builders' Association, by Mr. E. Hunter, of London.

A FIRE occurred on Sunday afternoon by which two of the largest warehouses in Buchanan Street, Glasgow, were destroyed, the damage being estimated at 100,000l.

A SPRING of petroleum oil has been found at Anderton, near Northwich, in the salt district, on the property of Messrs. Greenall & Co., brewers.

PLANS for public baths, prepared by Mr. I. M. Jones, city surveyor, estimated to cost 8,500l., were submitted at the monthly meeting of the Chester Town Council, and are to be exhibited to the public for approval in the next few weeks.

A DRINKING FOUNTAIN, presented by Mr. John Aird, M.P., to the Corporation of the City of London for the use of the public frequenting the Queen's Park, Kilburn, has just been formally opened.

A GYMNASIUM and workshop in connection with the Railway Servants' Orphanage at Derby has been opened by Mr. J. M. Cook, of the firm of Thomas Cook & Son, who has erected them for the institution at a cost of 500l.

AT the meeting of the Winsford Local Board on Friday a letter from the Salt Syndicate was read, offering a free supply of brine to the public baths on condition that the Board refused its consent to persons other than the Syndicate to lay brine pipes through the streets. At the same meeting a letter was read from a ratepayer, asking permission to lay pipes to connect a brine shaft with some riverside works.

MESSRS. HUGH KENNEDY & SONS are the successful competitors for the new railway station at Gourock, the brickwork of which is to be eight feet above the quay level. The roof is to be composed of steel girders, supported by cast-iron columns. There will be about 50,000 feet of glass in the roof. The length of the station is to be 320 yards, and the breadth 110 feet. There will be three passenger platforms about 40 feet in width, and the trains will run alongside the steamers, of which the railway company have already arranged for a first-class service. The work, which has already been commenced, will, it is expected, be completed by April 1, 1889, at a cost of about 20,000l. The Messrs. Kennedy have also secured the contract for the Inverkip Street station at Greenock.

A BRASS eagle lectern of singularly chaste design and beautiful workmanship has been presented to the church of St. Michael and All Angels by Admiral Edye. The shaft is massive and elaborate, and forms an enriched brazen pillar surmounted by a highly polished globe, on which the eagle stands. Round the base the following inscription is engraved:—"To the Glory of God.—Presented to the church of St. Michael and All Angels, Helensburgh, by Vice-Admiral William Henry Edye. September 1888." Messrs. Hardman & Co., Birmingham, are the makers.

MESSRS. DOULTON & CO. have taken a lease of two acres of ground adjoining the Seedhill Road, Paisley, on which a branch of their works will be erected.

THOSE of our readers who were interested in the visit of the colonial bishops to England this year will be pleased to learn that a handsome silver pastoral staff is to be presented to the Bishop of Qu'Appelle, Canada. The work has been entrusted to Messrs. Jones & Willis, of Birmingham and London.

### THE ENGINEER OF THE FUTURE.

THE introductory address of a series of lectures was delivered last week in the Engineering Department of the Yorkshire College, Leeds, by Professor Barr. He said:—The labours of engineers have always been recognised as among the most beneficent influences in promoting the civilisation of the world.

Since the birth of time, throughout all ages and nations,  
Has the craft of the smith been held in repute.

It is related of Dr. Arnold that on viewing a train on one of the first railways, he exclaimed, "I rejoice to see it, and to think that feudality is gone for ever: it is so great a blessing to think that any evil is really extinct." And so Carlyle writes, "Of the poet's and prophet's inspired message, and how it makes and unmakes whole worlds, I shall forbear to mention; but cannot the dullest hear steam-engines clanking around him? Has he not seen the Scottish brass-smith's idea (and this but a mechanical one) travelling on fire-wings round the Cape and across two oceans, and, stronger than any other enchanter's familiar, on all hands unweariedly fetching and carrying; at home not only weaving cloth, but rapidly enough overturning the whole old system of society, and for feudalism and preservation of game preparing us, by indirect but sure methods, industrialism and the government of the wisest?" Every one, then, will agree that few questions have a more direct bearing on the future of mankind than that of the progress of engineering practice. But the future of engineering practice must depend on the characters and powers of those who will carry on the labours of the engineers of to-day, and, therefore, we can appreciate the remark of the author of a paper on technical education recently read in America, that the education of engineers "is a matter of momentous interest to the whole civilised world." It is, at all events, a subject which

must not be passed over lightly as one which can take care of itself, nor must prejudice be allowed to govern our views regarding it. I think, therefore, that a brief consideration of the prospects which the future holds out for engineers cannot fail to be of interest to those who will have some share in their fulfilment. I have, therefore, chosen as the subject of my annual address to you "The Engineer of the Future."

My object is not to lay before you any prophecies of what the engineer of the future will *do*, as to show—with, I trust, good and sufficient reasons for the faith that is in me—what the engineer of the future will *be*. That he will have a wide field for his labours, and will have the honour of bringing about social revolutions as great and beneficent as those which resulted from the inventions of Watt and Stephenson, no one can doubt. But in what direction we must look for the next grand departure in his "art of directing the great sources of power in nature for the use and convenience of man"—whether in a great development of the gas-engine, or in the discovery of some cheaper and more direct source of electricity than we now command, or in something more unthought of, I shall not take upon me to predict. Of this, however, we may be certain: great advances will be made, and those will be "in it"—those nations, those firms, those men—whose knowledge will enable them to go beyond the ordinary routine of present-day practice. It becomes, then, a vital question, not only for us as engineers and as individuals, but for us as a nation, to inquire what methods will best insure to us the possession of those qualities of mind and hand which will enable us to strike out new and untrodden paths in invention and production.

There is no subject attracting more attention at the present moment than that of technical education and its bearing upon foreign competition, and there is perhaps none upon which more directly contradictory opinions are expressed by men who ought, at least, to have some knowledge of the subject. I do not propose to enter at length upon a consideration of technical education in its general bearings on the commerce and industry of the country. I would, however, point out in passing that the stock argument of most of those who hold that we have no need of that systematic training in science which other nations have so largely adopted to enable us to keep our position in the industrial struggle for existence, is that our manufacturers and manufactures have still a great hold on the markets of the world. These obtuse individuals remind me forcibly of an old domestic of my grandmother, who, when remonstrated with by her mistress for not wearing warm enough clothing in a severe

# FIRE! FIRE! FIRE!

## GRIFFITHS' "PYRODENE" FIREPROOFING LIQUID

(NON-POISONOUS).

Transparent Liquid for Rendering Woodwork Uninflammable,

Without altering its appearance, and where painting is not desired, such as Wooden Fittings in Exhibitions, Churches, Pews, Matchboarding, Theatre Scenes, Wooden Stairs, Joists, Beams, Floors, Factories, Stables, Mills, &c., in fact, Structures of an inflammable nature of all descriptions. Acts as a priming for new Woodwork for Paint or Varnish. Also for rendering Theatrical and Ball Dresses, Curtains, Paper, Felt, Canvas, &c., perfectly uninflammable.

Griffiths' Liquid penetrates the pores of the wood. It lasts as long as the wood itself. It prevents Dry Rot and decay in house timbers. It does not crack, peel, or rub off.

It is perfectly innocuous and free from smell. It will keep any length of time. Any one can apply it. One gallon will cover double that of any other priming.

All Woodwork in new houses should be fireproofed with this liquid, the cost is so trifling in comparison with the preservation of the timber and freedom from risk of fire. If work is desired to be painted afterwards, Griffiths' Pyrodene Paint is best for the purpose.

AND

## GRIFFITHS' "PYRODENE" FIREPROOF PAINT.

READY FOR USE.

NON-POISONOUS.

ALL COLOURS.

This Paint is manufactured for preservative and decorative purposes equally as for its FIRE-RESISTING qualities. The Fireproof Paint and Fireproofing Liquid is used at some of the principal Theatres in the United Kingdom.

### RECENT TESTIMONIALS.

From Messrs. MAXWELL & TUKE, Architects, 29 Princess Street, Manchester: December 28, 1887.

DEAR SIRS.—We used your Paints in nearly the whole of the works for the Royal Jubilee Exhibition, and with very satisfactory results.

Yours truly, MAXWELL & TUKE.

To Messrs. Griffiths Bros. & Co., Dashwood House, London, E.C.

From S. C. LOWE & SON, House Decorators, 32 Cavendish Street, Stretford Road, All Saints, Manchester: November 22, 1887.

DEAR SIRS.—In reply to your inquiry, we, as one of the contractors for the painting of the Manchester Jubilee Exhibition, which closed on the 10th of this month, have pleasure in stating that both your "Aqual" Paint, and also your "Pyrodene" Fireproof Paint, have given great satisfaction. We found them work easily with a covering power of from 30 to 40 per cent. over ordinary paint. Although applied during intense frost, and having been subjected to an almost tropical summer, followed by the drenching rains of this autumn, they are as fresh in colour and have as firm a grip as when applied, and appear quite unaffected by the nine months' exposure. We consider them, therefore, well adapted for all work in any climate.—Yours truly, S. C. LOWE & SON.

CHEAPER AND MORE DURABLE THAN ORDINARY PAINT.

GRIFFITHS' "PYRODENE" FIREPROOFING COMPANY, Limited,  
4 & 5 DASHWOOD HOUSE, NEW BROAD STREET, E.C., LONDON.

winter, replied, "When I didna dee last wunter, whatfor wud I dee this wunter?" It is too late to lock the door when the steed is stolen, and it is time that we heard the last of this old wifeism. The question is not how much of our foreign trade (and, for that part, also our home trade) remains to us, but whether our progress has been comparable with that of other nations. Yet the advocates of scientific training are challenged to prove "that the German iron trade is more prosperous than the English iron trade," and "that German iron and steel are better than English iron and steel." That is not the question, whatever its answer may be. We must look at the present position of manufactures in the countries which now compete with us, and compare it with the position thirty, or even twenty, or even ten years ago, and ask ourselves whether we or our rivals have made the most progress. In many industries, while our manufactures have expanded, those of other nations have grown from the seed. A stern chase is a long chase, but our lead in the race is fast being lessened.

Another favourite contention of the class of writers to whom I have referred is that in this country we have not yet been beaten off the field, though we have stuck (with true British doggedness) to our old methods, while other nations have gone in for this new-fangled education craze. I am not aware that the old wooden walls in which we once put our trust were ever wiped off the face of the sea by the navies of any other nation, but he would be a fool indeed who would therefore contend that we should continue to trust for our defence in oak, while other nations have their ironclads, and largely of our building too. So it is in this matter of scientific education. We have in a very large measure provided the science which other nations are now applying to their practice, and shall we alone continue to put no faith in it, while they use it to our destruction? I am convinced that we, as a manufacturing nation, are not sufficiently alive to the great danger which our prosperity in the past may be to us. We do not take the lessons which experience on a more limited scale within our own boundaries would teach us. The fate of Norwich—as referred to by Mr. Swire Smith, for instance—"Norwich, which one hundred years ago was the centre of the wool industry, and the most important manufacturing city in the country, refused to adapt itself to the new conditions. . . . It fought against the progressive spirit of the age, as men fight against it now, and it is recorded that in the beginning of the century, 'for anyone to set up machinery in Norwich was to venture his life.' The golden opportunity passed by, possibly never to return, and the

great worsted industry deserted its ancient stronghold, and took root among the enterprising people of the West Riding of Yorkshire."

Nor do we take the lessons of the history of nations. Frederick the Great introduced certain novelties of drill and manœuvre in the training of his armies, and through their influence he won most of his battles. But Napoleon introduced newer methods, while his rivals stuck to those which had secured them their greatness, with results that need not be detailed. The Germans took the hard lesson, and it bore its fruits in the war of 1870. These ups and downs of nations should suggest to us the question in relation to industry, Are we who have the field—and unbounded self-confidence as a nation besides—or are they who have to fight their way up to our position, and are determined to do it—are we or are they most likely to investigate and discuss with earnestness and success the best implements of warfare and methods of attack? Surely they are. It was ever so. Hence you may be certain that what other nations do so deliberately, and with so much thought and discussion, is what will, in all probability, be the best and strongest course. And, therefore, when we find other nations who are doing all in their power to rival us—America for example—adopting the most carefully drawn-up and complete schemes of scientific and technical instruction, we may feel sure that the matter has been well considered, and that, too, from a point of view much more likely to be unprejudiced than that of those in this country who rest upon our past success and greatness.

(To be continued.)

#### BRUSSELS EXHIBITION.

#### SAFETY FROM FIRE.

MR. JOHN AIRD writes from Brussels:—I have been making inquiries in Amsterdam, Vienna, and Berlin as to the methods adopted by the fire brigade for saving life from fire, and earnestly hope when Parliament reassembles that a committee or a commission will be appointed to investigate and report upon this important matter. At Amsterdam and Vienna life-saving appliances form part of the equipment to accompany the first engine, this comprising ladders, ropes, slings, canvas, &c., and in both cities the telegraphic arrangements are most complete. It but seldom happens there is any loss of life from fire. At Berlin the arrangements are very perfect. The police control the construction of buildings to insure escape. Notices are freely placed to make known the position of the police offices and fire-brigade stations. Children at school are educated as to the course they should adopt in case of fire, and all gas supplies can be cut off in a minute. The Metropolitan Board pass a resolution admitting the inefficiency of the present arrangements, and do nothing; the responsibility must therefore rest with the Government.

#### TENDERS FOR THE BIRMINGHAM LAW COURTS WINDOWS.

A LETTER has been addressed by Mr. Wm. E. Loder, of Birmingham, to the local *Daily Post* last Friday, in which he says:—Your issue of to-day contains two letters published by way of challenge to the decision of the Jubilee Committee respecting the stained-glass windows for our new Law Courts. In common justice to the successful firm in the competition, I ask you to give publicity to this protest. Your correspondent "F." takes exception to the expression that the tender for 1,700*l.* "being the lowest, was accepted." This demands but

slight notice, as the respectability of each competing firm was undoubtedly ascertained before its members were invited to submit designs, and this respectability being based on their many well-known productions, their reputation depends on their manufacture of really first-class windows. Again, "F." does not know, "even by name, the firm;" then, in the name of all that is genuine, I trust he will never commit himself again by advising on the matter of stained glass. Not to have heard of the firm who recently executed beautiful windows for the English church at Copenhagen—the firm which numbers among its patrons such influential clients, such devotees of the art, as the Duke of Westminster, Lord Egerton of Tatton, Lord Wolverton, the late Marquis of Ailesbury, and the leading architects of the day, is tantamount to possessing an infinitesimal knowledge of the trade and its chief exponents. The selected firm employs the most talented artists, and having in my professional career had many opportunities of visiting their show-rooms in London, I am convinced that lovers of the art in Birmingham may confidently rely on the new Law Courts possessing at the completion of the work some of the finest stained glass in the country. Such letters as those to which I am referring are calculated to prejudice the public mind; and my excuse for writing is that I may in some measure assure "F." and others harbouring similar dissatisfaction, that the firm to whom the stained glass is entrusted never sacrifice art to prejudice and censure.

#### FALL OF A HOUSE IN DUBLIN.

THE inquest held in Dublin by Dr. Whyte, the city coroner, owing to the death of a child, Esther Murphy, killed in the fall of a house in North Cumberland Street, was concluded on Friday.

Sergeant Halligan deposed that it was the duty of the sub-sanitary officers to report to the city engineer any unsafe tenements in their districts. They only inspected houses held in tenements, except when their attention was specially called to other dwellings. He found that the house 38 North Cumberland Street had been reported to the late city engineer (Mr. Neville) by sub-sanitary officer Michael Hackett on April 20, 1886. The inspection of houses was not a duty under the Sanitary Act, but lay in control of the Public Health Committee of the Corporation.

Thomas Williams, who occupied the back parlour of the house, deposed that ten or twelve weeks ago a portion of the

side wall of his room fell, exposing the rafters, and leaving no support for the end of the joists. He immediately reported the matter to the landlady, Mrs. Hearne, who, with her husband, occupied the shop on the same floor as witness. He told her there was no use plastering it, as the foundation of the back wall was completely gone. He subsequently prevented a man from plastering it, and nothing further was done to repair it. Three falls had occurred in the house previously—one of them over his head and another in the front drawing-room.

Mr. Harty, city engineer, deposed that there were two Corporation building surveyors, one for the north and the other for the south side of the city, connected with his department. Their duty was to look after new erections, and the duty of inspecting old houses lay with the eighteen sanitary officers, and the police also sent in reports, as did private individuals, and every case was inquired into. Witness had searched the records for the past eight years, and had found no report concerning this house except that made by sub-sanitary officer Hackett in 1886. The witness read the report, which was as follows:—"I also beg to draw your attention to the house 38 North Cumberland Street, the plank wall of which is cracked, and has been newly plastered; owner, Thomas Hearne." Mr. Neville had himself inspected the house, and found there was a crack in the wall of the next lane, but that there was no danger from it. As a matter of fact, that portion of the house was still standing.

Can you explain why the back of the house was not examined at that time?—I know that Mr. Neville examined every room in the house, and I believe that the other portion of the house was safe at the time. On inspecting the house, I found that it was a chimney-breast that had given way, and brought the floors with it. It was simply a chimney-stack built up against the walls of the other houses, and not tied to it at all. That was wrong, but it might still have been perfectly safe when Mr. Neville inspected it. House jobbers did their best to conceal cracks and other defects in their houses by covering them up with plaster, or papering them over.

Coroner: When the rafters become rotten, and they are covered up, is there any means to discover that condition of things?

Witness: There is not; but we try them by shaking the floors. The great danger is that these houses are converted from private dwellings into shops. The chimney-breast is cut away, and a beam put in upon which the whole private dwelling rests.

The Coroner: Can you prevent a man from doing that? Witness: Not as long as there is no danger. They could not interfere before an accident occurred. He thought that state of things should be remedied.

The Coroner said that was a matter for legislation.

Michael Hackett, sub-sanitary officer, deposed that he visited this house in April 1886, and reported on it. He afterwards heard that it was not in a dangerous condition. He had never been refused admission to any house.

Charles Verschoyle, Superintendent Barrack Street Cottages, deposed that he called the last witness's attention to the house in 1886. Every report he made was attended to.

A Juror: I think it is clear that the engineering department did not do their duty.

Mr. Harty protested against the engineering department being blamed when they did not deserve it.

Witness, in reply to Mr. Harty, said there was a house in Mecklenburgh Lane still standing which he had reported as dangerous.

If a professional man reported the house as not being dangerous, would you adhere to your opinion?—Certainly not. Every one of his reports was punctually attended to.

Sub-sanitary officer Kelly said he was the officer of the district at present. In April last he reported this house as being in an unsanitary condition, but not as being unsafe. He noticed nothing dangerous about it. His duty had not allowed him to inspect it since.

The Coroner said it was a very serious thing that a next-door neighbour might be endangering a house and no one interfere, unless it was absolutely dangerous at the time.

Mr. Thomas Parker, carpenter, said that it was a strange thing that men who knew nothing at all on the subject should be inspectors of houses.

The jury returned a verdict that the occurrence was accidental, and that they were of opinion that a closer watch should be kept over houses of the kind by the Corporation officials.

SOLE ADDRESS:—110 HIGH STREET (near MANCHESTER  
SQUARE), LONDON, W.

with its condition at the time of the British occupation exactly ten years ago, he says there then existed what was called a road between the principal port of Larnaca and the capital, Nicosia (26 miles), but as it was unmetalled it was impracticable in wet weather; it was scored with deep ruts, and those who have made the journey in the solitary vehicle that occasionally ventured between the two towns will not readily forget the shaking they had to endure. A cart-track had also been partially marked out from Nicosia to Kyrenia on the northern coast (16 miles), but I have not heard that any vehicle had ever succeeded prior to the occupation in accomplishing the journey. Besides these there was in 1878 no other vestige of a made road throughout the island. At present about 400 miles of main roads have been laid out, and of these the earthworks and drainage of three-fourths of that length have been completed, and upwards of 200 miles have been metalled or gravelled, so as to be serviceable for wheeled traffic in all weathers. It is true that much remains to be done by forming the connecting links to complete the main lines of communication. The works are, however, so far advanced that were funds available the main roads (by which I mean those that connect the capital with the chief towns of the various districts and these with each other) might be completed in little more than a year and for a comparatively small sum. The advantages of the improvement in the communications already effected are manifest to all acquainted with the island. Instead of an occasional omnibus there are now four or five daily in each direction between Nicosia and Larnaca, besides numerous private carriages, and the cost of the transport of merchandise has been reduced one-half. A system of cart roads has been carried through the mountains of the Limassol district, reaching a summit level close on 3,000 feet above the sea, for connecting the principal wine-growing villages with the port of shipment.

As regards bridges, besides hundred of smaller bridges and culverts, some of the principal torrents have been spanned by works of considerable magnitude. Of these I may perhaps be allowed to mention an iron girder bridge over the Pedias of three spans, each of 40 feet, and compound iron and timber bridges over the Idalia, the Vasilikos, and the Limnati torrents of from 120 feet to 210 feet of waterway. Besides new bridges, many of the ancient bridges which we found in a ruinous condition have been restored and rendered serviceable.

Shortly after my appointment as Government engineer in 1880 my attention was called to the Pedias Canal, which

supplies water to the best part of the rich plain of the Messaoria, and is the most extensive irrigation system in Cyprus. The ancient channels had been allowed to silt up, and the banks were so breached that the canals were altogether unserviceable. They have since been cleared out, the derivation weir reconstructed, and the breaches in the banks repaired; and during the past seven years the works have been maintained in an efficient state, and thereby the value of the crops from the area watered by the canal has been augmented by an annual sum of at least 10,000*l.* Last year a law was passed empowering the Government to advance money and carry out irrigation works, and various schemes are now under consideration. That more has not yet been done may be due to the fact that it takes some time for the peasant proprietors to consult together and agree as to the works it may be deemed desirable to carry out.

It is perfectly true that a safe deepwater harbour is one of the great wants of Cyprus, but as a work of this nature is naturally one of some magnitude, it would appear that no Government has yet thought fit to apply to Parliament for the necessary funds. From its geographical position on the northern side of the island, it would be a fatal mistake to construct a first-class harbour at Kyrenia, that port being out of the line of direct communication with Europe and Egypt, while on the other hand, as it lies exactly opposite the coast of Asia Minor, from which it is separated by less than fifty miles of sea it is admirably situated for carrying on, and has always maintained, a trade with the mainland, and it was to afford shelter to the coasting craft engaged in this trade that the breakwaters were designed and are being constructed by convict labour for the comparatively small sum of 8,000*l.* That the works, although now unfinished, will answer the purpose for which they were designed is proved by the fact that last year the trade with Asia Minor was (for the first time since Kyrenia became a port centuries ago) carried on throughout the winter, instead of the local craft being hauled up on the beach, as they invariably were in previous years every autumn as soon as the weather broke. Besides Kyrenia Harbour, the following maritime works have been executed since my appointment, eight years ago:—An iron pier at Limassol, 600 feet long, carried out into 20 feet of water, provided with cranes and placed in communication with the Customs warehouses by means of a tramway; an iron pier at Larnaca, 450 feet in length. In addition to these piers four iron jetties for lighters have been constructed—at Larnaca, at Limassol, at the Carub shipping station on the

coast at Ziyi, and in the ancient harbour of Papho. Harbour lights have been provided at Kyrenia, Famagusta, and Limassol, and an important coast light is in process of erection at Cape Papho, the south-western extremity of the island and the point first made by vessels approaching it from the westward.

### COURT THEATRE, VIENNA.

THIS theatre was opened on the 14th. The *Times* says:—The sight of the auditorium, lit by electricity with 4,000 16-candle power lamps, was beautiful in the extreme. The decorations of the house are white and gold, the coverings of chairs, boxes, and stalls of ruby plush. The gorgeousness of the foyers and lobbies, and especially of the retiring-rooms attached to the Court boxes, almost passes description. In fact, the eye turns with relief from all the gold, polished marbles and scarlet draperies to the admirably executed mural and ceiling pictures to be found in every part of the house. It has taken thirteen years to build the theatre, and Baron Hasenauer, the architect, has produced a work beyond comparison finer than any theatre ever constructed or dreamt of. He has especially kept in view the safety of audiences, so that the space occupied by staircases, corridors, and lobbies is quite double that allotted to the auditorium and stage. Two vast staircases of palatial magnificence, ascending without any turn to the level of the first floor, give access to the boxes right and left of the house. These staircases fill up two wings, extending from the rotunda which forms the centre of the building. There are also separate entrances for pit-stalls and galleries. Ante-rooms are attached to every box. These open on to semicircular corridors, and from these access is obtained to the semicircular foyers. The doors are so many and so wide that no panic could produce a crush. Upon every floor the audience, rushing out, would disperse itself easily through the vast foyers, and find its way to the doors of exit.

### PEOPLE'S PALACE CLASS OF MASONRY.

At the People's Palace, Mile End Road, a class for the study of the science of masonry has been organised. It is conducted by Mr. Lawrence Harvey, F.R.I.B.A., with the assistance of four of the leading master masons of London. The class met

for the first time on Saturday, the 13th inst., at six o'clock, and was numerously attended, the number of applicants being much greater than the class-room can possibly accommodate.

Mr. Harvey opened the proceedings by stating that a few days ago he was expressing to Sir Philip Magnus his regret that the petition signed by nearly 400 masons for the establishment of such a class at the City and Guilds of London Institute could not be granted, when Sir Philip remarked that petitions had very little value; nothing was so easy as to get signatures, but would the signers come? That was the question. Now, here, at the People's Palace, were more than thirty men who had most of them travelled over two hours to attend this class. They had come from Putney, Peckham, Lambeth, Wandsworth, Kennington Lane, Vauxhall; and it was reasonable to ask, would they not have come in still larger numbers to the Guilds Institute, which was much nearer their homes? This was their practical answer to Sir Philip Magnus's question. Another idea which found much favour outside the working classes was that "workmen only require a smattering of knowledge." This idea was entirely false. The workmen who had advised the men who were present to join this class did so after following the course of lessons given to architects by Mr. Harvey—a course in which, as stated by a great mathematician, Professor Henrici, very high questions of geometry were treated. What is needed is not second-rate science, trimmed down to suit workmen, but the very science professional men boast of possessing. Workmen want to know all there is knowable, and not an atom less. Mr. Harvey then described the part master masons took in the erection of our old cathedrals, and quoted several recent instances of masons who had risen to eminence as architects. Amongst the advantages enjoyed by architects risen from the ranks of masons was their intimate acquaintance with workmen, which enabled them to select thoroughly trustworthy clerks of works.

After this introductory discourse Mr. Harvey called on Mr. Wornell, foreman of masons in the works of Mr. Nightingale, Lambeth, to deliver a lecture on English quarries and the preliminary work previous to quarrying. In the course of his lecture Mr. Wornell exhibited a collection of specimens of the stones used in London, and explained their properties, advantages, and defects. Mr. Wornell's lecture was followed with the greatest interest, and in every way this first meeting of the People's Palace class of masonry can be considered a great success, and amply proves how much classes of this kind are required all over London.

N.B.—The Interceptors and all other Traps are absolutely self-cleansing, and dispense with grease collectors. Illustrated List, also "Instruction in Sanitary Construction" (Domes Section, abbreviated), and "Memorandum on House Sanitation and the Law of Landlord and Tenant thereon," by R. Weaver, C.E., F.C.S., Sanitary Surveyor, free by post.

The Domestic Engineering and Sanitary Appliances Company, 24 High Holborn, London, W.C.

## REGISTRATION OF PLUMBERS.

THE West of Scotland Technical College authorities and the District Council, acting in conjunction with the Plumbers' Company, have started technical classes for plumbers. The introductory lecture was delivered on Thursday night in the large hall of the Christian Institute, Glasgow. There was a very large attendance, upwards of eight hundred plumbers—masters, operatives, and apprentices—from all parts of the district being present. Mr. Thos. Russell, one of the governors of the Institute, presided, and, in introducing the lecturer, urged the students to remember the responsibility for human life which rested with plumbers. The lecturer was Mr. J. W. Clarke, the first practical plumber who succeeded in obtaining the company's freedom by passing in honours the prescribed examination in the principles and practice of the craft. Professor Jamieson and several of the governing body of the Institute were present, and it was mentioned that upwards of seven hundred plumbers had already been registered in the district.

The following is a list of plumbers registered since September 1, 1888:—

*London Master.*

WHEELER, G. J., 3 Russell Road, Wimbledon.

construction of baths." October 5, 1888.  
14334. Carl Prockl and Franz Fortelka, for "Contrivance  
for measuring distances, system Fortelka-Prockl, 1887." Oc-  
tober 5, 1888.  
14340. James Cosmo Newbery and Claude Theodore James  
Vantin, for "Improvements in the process for the treatment of  
sewage." October 5, 1888.  
14341. James Cosmo Newbery and Claude Theodore James  
Vantin, for "An improved process for the separation of fine  
clayey matter from a liquid in which it is suspended." Octo-  
ber 5, 1888.  
14354. Henry Smith Edwards, James Harry Edwards, and  
George Straket Falck Edwards, for "Improved process of manu-  
facturing cowls and apparatus therefor." (Complete specifica-  
tion.) October 5, 1888.  
14364. Francis Murray Rogers, for "An improved silent  
fastener for doors, windows, and like purposes." (Stewart  
Reid, New Zealand.) October 6, 1888.  
14377. Joseph Kaye, for "Improvements in means for  
operating fastenings for exit and other doors." October 6,  
1888.  
14382. Thomas Dalton, for "Improvements in apparatus  
for opening, closing, and securing skylights, fanlights, case-  
ment and sash windows, and louvres." October 6, 1888.  
14422. John William Bernhard Wright, of the firm of  
Wright & Butler, for "Improvements in the construction of  
stoves and tile hearths for stoves." October 8, 1888.

14423. Henry Metcalf, for "An improved ventilator." Oc-  
tober 8, 1888.  
14439. Frederick Simpkin, for "A safety sash window-  
frame." October 8, 1888.  
14450. James John Pearson and Tom Henry Taylor, for  
"An improved double-acting pump for the pumping or  
circulating of fluids." October 9, 1888.  
14454. Benjamin Talbot, jun., for "Improved rain-troughs  
for the roofs of buildings." October 9, 1888.  
14483. George Harper, for "Locks and keys." October 9,  
1888.  
14491. William Sayer, for "Improvements in apparatus for  
making bricks, tiles, and similar articles from plastic clay and  
the like." October 9, 1888.  
14496. Robert Mansell, for "Improvements in *portière* or  
door curtain rods, and in fixing the same in position." Oc-  
tober 9, 1888.  
14530. Eldred Wilson Head, for "Improvements in moulds  
for moulding and dressing bricks, blocks, and slabs, applicable  
also for expelling moisture from clay, whiting, prepared fuel,  
peat, and the like." October 10, 1888.  
14539. Thomas Stephenson, for "Certain improvements in  
earthenware tiles." October 10, 1888.  
14542. Reginald Wilmot Hayes Newington, for "Improve-  
ments in electric and other bells." October 10, 1888.  
14547. William Parry, jun., and Richard Griffith, for "A  
new automatic keyless lock." October 10, 1888.  
14575. Henry Harrington Leigh, for "Improvements in  
coke ovens." (Theodor von Bauer, Germany.) October 10,  
1888.  
14587. Isaac Kirkbride, for "Improvements in window-  
sashes." (Complete specification.) October 11, 1888.  
14596. Robert Thompson McHeenan and Samuel Hudson  
Pellar, for "Crown spring hinge, for automatically raising the  
seats of water-closets when not in use." October 11, 1888.  
PROVISIONAL SPECIFICATIONS ACCEPTED.  
9403. William Thomas Symons and Lewis Prust Symons,  
for "Improvements in material for floors and floor and wall  
coverings, and applicable for other purposes." June 28, 1888.  
10219. Robert Williams Gamble, for "A new or improved  
combined door spring-alarum." July 13, 1888.  
13155. William Joynson, for "Improvements in, and con-  
nected with, roof gutters." September 12, 1888.  
13326. John Hawthorn, for "Sinking metal cylinders,  
lining or tubing for heading shafts or wells employed in

This work will be presented to EVERY ARCHITECT whose name appears in "The Building Trades  
Directory for England, Scotland, and Wales."

## THIRD YEAR OF ISSUE. THE

# ARCHITECTS', SURVEYORS', AND ENGINEERS' COMPENDIUM, AND COMPLETE CATALOGUE.

EDITED BY JOHN ED. SEARS, A.R.I.B.A., F.A.S., AND C. STANLEY PEACH.  
ILLUSTRATED BY MAGNIFICENT PLATES.

## IMPORTANT NOTICE.

The next issue will contain a **DICTIONARY OF MANUFACTURERS' SPECIALTIES**, and the Editors will be pleased  
to receive particulars or catalogues of goods, with the leading specialties marked. Names of approved specialties are inserted **WITHOUT  
CHARGE**. The special feature of the work is **THE COMPLETE CATALOGUE**, in which detailed and priced particulars of  
goods, with each article indexed, are brought together and classified for the reference of Architects, Contractors, and others.

## TESTIMONY OF MANUFACTURERS.

**NOTE.**—Of the Firms who have already taken space, Seventy have ordered from 1 to 8 pages and upwards each, and the  
following and others have taken greatly increased space:—

D. Bostel, 1 page (increase from  $\frac{1}{2}$  page).  
Broad & Co., 8 pages (increase from 1 page).  
Burt & Potts, 2 pages (increase from  $\frac{1}{2}$  page).  
Doulton & Co., 2 pages (increase from  $\frac{1}{2}$  page).  
Maw & Co., 2 pages (increase from  $\frac{1}{2}$  page).  
Richardson, Ellson & Co., 2 pages (increase from  $\frac{1}{2}$  page  
in first and 1 page in second issue).  
S. Saunders, 1 page (increase from  $\frac{1}{2}$  page).

J. Wright & Co., 2 pages (increase from  $\frac{1}{2}$  page).  
Hitchins' Fireproof Plastering Co. write:—"Was  
of great service to us. We can distinctly trace several good orders  
to it."

James Brown writes:—"Has resulted in business with  
several firms in the course of the year."

Thos. Gregory & Co. write:—"We have proved its  
worth." "We find that a great benefit has accrued to us from this  
excellent method of advertising."

## SPECIMEN OPINION OF ARCHITECTS.

R. Norman Shaw, Esq., R.A., &c., writes:—"I am quite certain it would be of the greatest value, and secure universal support.  
Manufacturers' Catalogues are of very little use, and go freely into the waste-paper basket, as they are so numerous that it would be impossible  
to keep them, and unless kept systematically they would be of no use. At least, I know when I set to work to find a name or address I rarely  
succeed."

Full particulars of JOHN E. SEARS, 16 NEW BRIDGE STREET, LONDON, E.C.

making foundations, or in mining, tunnelling, or well-sinking." September 15, 1888.

13579. Abraham Stokes, for "Improved guiding apparatus for gas-holders." September 20, 1888.

13761. Alexander Bobrownicke, for "Improvements in the treatment of town refuse and other putrescible matters." September 24, 1888.

#### COMPLETE SPECIFICATIONS ACCEPTED.

Notice is hereby given, that all persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the date of the official *Journal*, give notice at the Patent Office in the prescribed form of such opposition.

15141. John Cardwell and James Chander, for "Improvements in bolts for securing shop-window shutter-bars, sliding-sashes, and for other analogous purposes." November 7, 1887.

15476. Ezra Lofts, for "Improvements in or relating to ventilating." November 12, 1887.

16877. Hiram Stevens Maxim, for "Intermittent water discharge, applicable to the washing-out of drains, water-closets, and to similar purposes." December 8, 1887.

16924. Benjamin Joseph Barnard Hills, for "Improved extinguishing apparatus for circular or Argand oil-lamps." (Anton Weiseman, Germany). December 18, 1887.

185. Alfred Clifford, for "Improved waterspray apparatus for extinguishing fires." January 5, 1888.

2199. Francis Joseph James Gibbons, for "Improvements in hanging centre-plates for fanlights, applicable also to other analogous purposes." February 14, 1888.

2886. Francis Joseph James Gibbons, for "An improvement in sash pulleys for windows; applicable also to pulleys for other purposes." February 27, 1888.

10913. George Davies, for "Improvements in drain-traps." July 28, 1888.

12589. Henry William Joseph White, for "Improvements in window and other fasteners, specially applicable to sashes, casements, doors, and for other similar purposes." September 1, 1888.

12771. Richard Cardwell Robinson, for "An improved construction of die for use in brickmaking machines." September 4, 1888.

PATENTS SEALED, OCTOBER 12, 1888.

11966. James Bazeley Petter, for "Improvements in stoves and fireplaces." September 3, 1887.

12467. Alfred Winrow and Herbert Roe Tandy, for "Improvements in brickmaking machines." September 14, 1887.

13127. Aaron Stephenson, for "An improved butt hinge and method of fixing same to doors." September 28, 1887.

13258. William Harry Dutton, for "Revolving doorpost or other revolving posts for public buildings or others." September 30, 1887.

16276. William Wemyss Kennedy, for "Improvements in or connected with gas lamps or burners, including the carrying of shades and appliances relating thereto." November 26, 1887.

9556. Albert Elmendorf, Stephen Ayrautt Gardner and Charles Prentis, for "Improvements in water-closets." July 3, 1888.

#### ABRIDGMENTS.

"Improvements in means of, and apparatus for, fastening and securing blocks of wood and analogous materials in position when used for flooring and other purposes. No. 14716. 1887. A. J. Hopkins, 27 Mortimer Street, London.

*Claim I.*—The method of securing blocks of wood and analogous substances by means of metal pieces or nails, each nail having a double shoulder or encircling-rest for the punch, as set forth, the front ends of the said nails being inserted into the one set of blocks by means of a driver, such as shown, and then have other blocks forced on to them, all substantially as and for the purposes set forth.

"An improvement in glazing." No. 372. 1888. Wm. Gibbs, 397 Kingsland Road, London.

*Claim I.*—The drawing of brass, copper, or other hard metal either from cast bars, sheet, tube, or the like to the required sections of ordinary "lead-glazing," substantially herein described, and according to the accompanying drawings.

"Man-hole cover for sewers and drains." No. 11762. 1888. Elliot Emanuel, 53, 55, and 57 Marylebone Road, London.

*Claim I.*—The form of recess of india-rubber which cannot be pulled out when the cover is taken off, substantially as described in the specification.

*Claim II.*—The groove in the india-rubber which secures an air-tight joint, substantially as described in the specification.

TO INVENTORS.—Patents for Inventions, Trade-marks, and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & CASSELL, Patent Agents, 43 Southampton Buildings, Chancery Lane.

# The Architect.

## THE WEEK.

MR. WATERHOUSE will deliver his presidential address on Monday evening, November 5, when a large number of members will be sure to attend. Although a zealous member of the Institute and the Manchester Society, Mr. WATERHOUSE has been chary about writing papers or speaking. Among the topics with which it would be well to deal two are mentioned in the last number of the *Journal of Proceedings* of the Institute. One is the Benevolent Society, which is not aided in proportion to the increase of members of the Institute. It is said that "Although the applications for relief have been more numerous, yet, during the last three years, the income obtained by subscriptions has not increased to any appreciable extent; while a comparison of the subscriptions received in 1883 (344*l.* 19*s.*) and those in 1887 (334*l.* 12*s.*) shows a decided falling off. The number of members of the Institute has considerably increased of late years, and it is hoped that more will subscribe to the Architects' Benevolent Society than has been the case hitherto." An appeal from Mr. WATERHOUSE would do much to help the Society. The condition of the library also indicates the indifference of the members. It appears that the "desiderata" have been supplied during the last nineteen years at the rate of a trifle over one per cent. per annum. Foreigners appear to be more liberal in proportion to their number than the English members. It is related that during the last three years, of 269 donations by members, 186 were made by British and 83 by foreign members, and 173 donations were made by non-members, 131 being by British subjects and 42 by foreigners. At one time it was supposed that a visit to the library was waste of labour, but the convenience of readers is more studied now, and if the library is allowed to exist it ought to show some approach to completeness.

A PAPER on the Temple of Apollo at Delphi, by Professor MIDDLETON, was read in part at a meeting of the Hellenic Society on Monday. The temple, of which remains exist, was the fifth on the site, and was built by means of a subscription raised throughout Greece under the authority of the Amphictyonic Council. The Alcmaeonidae of Athens were the contractors. The architect was SPINTHARUS, a Corinthian. Professor MIDDLETON showed that the temple was hexastyle and peripteral in the Doric order, with the probable dimensions of 192 feet by 72 feet 6 inches on the top step. It was built of limestone, coated with the finest stucco. Comparing the style of the details with those of other Doric temples, Professor MIDDLETON conjectured that it must have been later than the temple of Corinth, and possibly also than that at Aegina. After reference to his conjectural restoration both of the temple and of the subterranean oracular cell, the writer spoke of the wall enclosing the *temenos* as of the finest Greek masonry, and remarkable not only for its construction but for the fact of its face being covered with closely-cut inscriptions, dating from the end of the third century B.C. to the time of HADRIAN. In the course of the discussion which followed it was pointed out by Mr. F. C. PENROSE, as the result of recent explorations on the Acropolis, that the older Parthenon was built not of marble but of limestone covered with fine stucco, and also that Ionic capitals came into use in Greece earlier than had previously been supposed. Mr. FARNELL recommended excavations on the site of the temple, as it might be ascertained whether the *Apollo Belvedere* and the *Stroganoff Apollo* did not commemorate a repulse of the Gauls from Delphi by the agency of the god.

A CORRESPONDENT complains that in a paragraph last week the name of ALEXANDER THOMSON was not associated with the reference to the "travelling studentship" of the Glasgow Society of Architects. The omission is to be ascribed to the official report. No slight was offered to the shade of the architect in London or Glasgow. The Society

possesses only one travelling studentship, and architects know that it was founded as a memorial of ALEXANDER THOMSON. Our own experience is that men who do nothing to promote THOMSON's fame, and, in fact, deride his style, profess to be the most touchy about the quality of his work when it is noticed by strangers.

THE Germans, after exploring Olympia, and drawing from it the fine examples of sculpture, do not appear to have taken much pains to preserve the remains of the temple. Mr. HAROLD PARSONS says that, during a visit in last spring, he spent most of his time in destroying the young pine trees, often 5 feet high and more, whose roots had penetrated the calcareous stones in all directions. The ravages of the asphodel were also serious, and the weeds with which the gigantic drums of the pillars were covered, when uprooted invariably bring away a mass of disintegrated rubble and shells. The ground-plan of the temple precinct can be made out, but unless care is taken the limestone will be overturned by the vegetation. Mr. PARSONS proposes that the Society for the Promotion of Hellenic Studies should invite subscriptions towards the provision of a caretaker for the ruins themselves, such as those provided by the Hellenic Government for Delphi and Eleusis.

THE new Shaftesbury Theatre, of which Mr. PHIPPS is architect, has a depth of 58 feet 4 inches from curtain to back of pit, and from curtain to back of stage the depth is 45 feet. The stage is 30 feet in width and 27 feet in height. The theatre can accommodate 1,800 persons. The hangings are of plush, a rich brown colour, lined with salmon-coloured silk. The colours of the decorations are light French grey and gold, and the walls of the theatre are covered with a dark terra-cotta paper. The stage is separated from the auditory by Mr. MAX CLARKE'S Patent Protected Iron Curtain, manufactured by Messrs. CLARKE, BUNNETT & Co., covered on the audience side with green baize, and worked by hydraulic power supplied from the mains of the Hydraulic Power Company, which run up in the subway underneath Shaftesbury Avenue. The auditory is at present lighted by one of Messrs. STRODES'S sunlights, but it is proposed very shortly to instal the electric light all over the building. The ironwork was supplied by Messrs. MORLAND & SON, and the general contractors were Messrs. PATMAN & FOTHERINGHAM. The theatre is isolated on all sides, and egress for the auditory is afforded by thirteen doors.

THE remarks of Consul-General DUNDAS, in his last report on the trade of Hamburg, deserve attention in this country. He says that, "Notwithstanding British manufacturers and merchants may pooh-pooh the possibility of their being cut out by German trade, it is nevertheless slowly but surely making its way, and attaining proportions the more alarming from its silent and undemonstrative progress. Germany's efforts have been directed to one end with a steady persistency—and that not unsuccessfully—to emancipate her trade from foreign hands, and to get it within her own control." As proof of what is being done, the Consul explains that the trade of Great Britain and the Australian Colonies with Hamburg amounts to 21,000,000*l.* a year. He suggests that English producers should endeavour to foster the notion of the superiority of English goods; but, unfortunately, the Germans are able in many cases to controvert an assumption of that kind.

THE Brown-book of the Association is now a fairly-sized volume, since it contains 177 volumes, or ten more than last year. No other directory of an architectural society can show so many signs of activity as are to be seen in the elementary and advanced classes, lectures, and other aids to knowledge. The number of members has increased from 993 to 1,052, the majority, as usual, coming from London. Everything that is practicable is done to give help to members in the provinces, and there should be more than 224 of them on the rolls. Among the additions is the prospectus of the Cycling Club, which is likely to grow into a useful institution. The session begins well, and under Mr. APPLETON'S presidency we may expect further developments.

## KIRBY HALL AND WELDON STONE.

KIRBY HALL in Northamptonshire was at one time among the stately homes of England, but it is now in a condition that must excite indignation as well as regret. Within the memory of men who are still living that house was habitable, but some years back the then possessor appears to have resolved that his heirs must seek a home elsewhere. His lordship began with selling the lead that covered the roofs to a pedlar for a small sum, and the money, it is said, was never paid. The noble lord was, we imagine, no less generous in disposing of other materials, and if Kirby Hall was not used as a source of supply for wood and stone, then appearances are deceptive.

The history of the building is not clear. According to one account it was erected for Sir HUMFRED STAFFORD. The boar's head crest, the initials H. S., and inscriptions in stone would support that view. Afterwards the house is supposed to have passed to Sir CHRISTOPHER HATTON in exchange for Holdenby. It is maintained, also, that Kirby Hall was always the property of HATTON, as it was erected at his expense, and the fine outer gateway certainly bears his arms. JOHN THORPE records that he laid the foundation-stone of Kirby Hall in 1570. In the following century INIGO JONES was commissioned to make some alterations.

The exterior shows two modes of treatment. As seen from the park on the west side, the Hall bears a resemblance to many Elizabethan buildings, and the most remarkable feature will be found in the great bow windows. But more of the Italian spirit will be seen in the court and in the parts near the porch. THORPE believed in the advantage of pilasters, which he employs with much skill. This will be suggested by the sketch of the Hall which appeared in this journal a fortnight ago.

HATTON is said to have won the favour of ELIZABETH through his dancing in a masked ball given in her honour by the Inns of Court. He was appointed gentleman of the Privy Chamber, and was in the constant receipt of valuable presents from the Queen. It was ELIZABETH'S custom to give her courtiers from forty to fifty ounces of plate on each New Year's day, but on those occasions HATTON obtained four hundred ounces. In 1572 he became captain of the guard, and the next year, when ill, he was sent to Spa with the Queen's physician as one of his attendants. Subsequently he was made vice-chamberlain and a privy councillor. In 1582 he retired from court through jealousy of RALEIGH. He was brought back and rewarded with the chancellorship. Although he was unskilled as a lawyer, his good sense brought him commendation—"Splendissime omnium, quos vidimus, gessit," says CAMDEN. ELIZABETH honoured HATTON with a visit in 1589. The expense of the preparations bore heavily on the chancellor, but it was not his only grief. Money was needed at the time for the public defence. The Queen, while at Kirby Hall, claimed an immense sum from HATTON for first fruits. He was unable to pay, and soon afterwards he died. Holdenby was sold to raise the money.

Kirby Hall was therefore built out of moneys which came from ELIZABETH. No country knight at the time could otherwise undertake a work having so much grandeur as was seen there. It was not only costly to build, but needed an enormous outlay to keep up, and, with all his income, it was as much as Sir CHRISTOPHER HATTON could sustain. Some allowance should accordingly be made for his inheritors when they wished to be clear of the building.

In these latter days, when landed property in England can barely pay the charges upon it, how many proprietors would have the courage to dream of the restoration of a building which has by degrees fallen into the condition of Kirby Hall? Lord WINCHILSEA has, however, resolved to make the attempt, and hopes to find the money which is necessary by selling the stone which is to be found on part of his estate at Weldon, where, at one time, quarries were opened.

On Friday last a great many architects and builders accepted Lord WINCHILSEA'S invitation to visit Kirby Hall, and afterwards to examine the new quarry. It was a treat to the majority. Kirby Hall is not familiar to every architect, and it could be examined on Friday in good company. There were no amateurs to spoil the enjoyment by

crude theories, and it was possible to study and sketch without a fear of being bored. It was no wonder that so many architects endeavoured to grow young again, in emulation of Mr. EWAN CHRISTIAN, who appeared to be able to see more of the building than any of his companions. But as Weldon stone on Friday assumed greater importance than Kirby Hall, it is right we should lose no time before speaking about it.

In the report of the commissioners who were appointed to seek after the most eligible stone for building the Houses of Parliament, there is no mention of the Weldon quarries. Northamptonshire, which is rich in stone, is represented in that document solely by the oolite from Barnack Mill, near Stamford. Weldon stone was, however, at one time recognised as possessing many good qualities, but in 1839 the commissioners would have had some difficulty in obtaining a sample, for the quarries, in common with the rest of the estate, were neglected by the owner. According to local tradition, which is not to be despised in such cases, Weldon stone was used in Old St. Paul's. It may have been the material that was specified for constructing the vault of King's College Chapel, Cambridge; and it is recognisable in the walls of churches and other buildings in Northamptonshire. What is called Ketton stone in some descriptions appears to have come from one of the Weldon quarries.

A glance at a geological map will show that Weldon lies upon the oolite formation, which may be described as stretching from the Humber to the Severn. There are several varieties of oolites, but generally their granular character is so marked as to give rise to the theory that they are derived from ancient coral beds. The Weldon stone might be selected as a typical oolite. When taken from the quarry it is a dark shade of the colour which, for want of a better word, is called "creamy." After a time it becomes grey. In its original, as in its transformed state, the colour is very pleasing. The stone is homogeneous and close in grain, it weighs about 140 lbs. to the cubic foot, and in other ways has some analogy with Ancaster. The crushing weight, according to MESSRS. KIRKALDY, is 140 tons per square foot.

It must be said that whoever had charge of the arrangements at the quarry at Weldon on Friday last, was not aware of what is essential if an architect has to judge of the value of a building stone. An experiment could only be conducted in a manner that was not satisfactory, and was hardly likely to serve the interests of the owner of the quarry. There was no preparation for any tests. For instance, when water was poured on the side of a block, which would be the part to withstand rain, it was absorbed with a rapidity that was remarkable. The phenomenon was enough to raise a prejudice against the stone. It is quite possible that some of the stones which were discovered to be so peculiarly porous were only a few hours out of the quarry, and if they had been properly seasoned one might have observed a different result. But in order to ascertain the absorptive power of a stone something else is needed besides dashing dirty water upon its face. Specimens ought to be shown which were soaked in water for several days, and means provided for weighing stones in a dry as well as in a saturated state. It is not difficult to suggest the influence of the atmosphere by a process that is comparatively simple, and it might have been employed at Weldon without incurring much expense. As regards the workable qualities of the stone, nothing was to be seen that had lately passed through the hands of a mason.

It is to be regretted for his own sake that Lord WINCHILSEA had not consulted an architect or a contractor about his arrangements. If builders like Mr. THOMPSON, of Peterborough, Mr. DENNETT, of Nottingham, or Mr. PATTINSON, of Sleaford, who were all present, had been asked for advice, the quarry must have presented a different appearance. They would be able to bring forward the kind of evidence which is needed, if the qualities of a stone are to be recognised by architects.

If, through mismanagement, it was difficult to realise the value of Weldon stone from a visit to the quarry, fortunately there were other means available for the visitors. Kirby Hall and Geddington Cross were enough to convince the most sceptical. In the former ingenuity seems to have been exercised to bring the building to ruin. But, in spite

of all that could be perpetrated by the owners to aid the work of time, the condition of the masonry might be said to be perfect, and the carving seems to retain its original sharpness. The fluting of the pilasters and the most exposed arrises continue to be true in line. Where finials remain they retain all their parts unbroken. Indeed, the strangeness which strikes a visitor on first seeing the building is partly owing to the contrast offered by the soundness of the masonry with the frailty of the carpenter's work and the absence of roofing. We can see there a remarkable example of what lawyers call "extraordinary decay." If a wall should need reparation in any part it is owing to man's hand, for the stone seems capable of resisting atmospheric agencies for ages. On looking at Kirby Hall one feels that an exceptional cause must have brought about the destruction of a material that was made to endure, and that it operated in a capricious manner. Ruins are not uncommon in England, but we doubt if another can be found which is so much of a puzzle in its combination of strength and weakness as the seat of the HATTONS.

Geddington Cross was erected about three centuries earlier than Kirby Hall, and was more exposed to danger. It stands in an open space in the village, and has figures and symbols which at one time would be regarded as accessories of a superstition, and which a loyal and orthodox man was bound to destroy. Geddington was not an excitable place, and as the structure found few enemies among the inhabitants, it has survived the wear and tear of six centuries. It is, in fact, the best preserved of the Eleanor Crosses. Assuming that Weldon stone was used in its construction, we must admire the toughness of a material that after so long a time presents the most delicate detail of the canopies on the three sides, as if it were the work of yesterday.

Rushton Hall, which was afterwards visited, is also an example of what can be done with Weldon stone. This large mansion is now occupied and forms a most comfortable dwelling. There was, unfortunately, no time for so close an examination as the building deserves. It is not as consistent an example of Elizabethan work as Kirby Hall, for the builders were able to employ mouldings and ornament which would appear more apposite in a building of earlier style, as they were evidently modelled on Mediæval precedents. But few would care to think of details when impressed with the general effect. The house must have undergone restoration, for the residents need not suffer inconvenience for the sake of archæology. The grounds are laid out in a way that would gratify a landscape painter, and the remarkable triangular tower, which was erected by Sir THOMAS TRESHAM, forms a termination for some of the avenues. The tower is also said to be constructed of Weldon stone, and the symbolic devices which cover the front will, therefore, long remain as a testimony of the designer's faith, which no sufferings could overcome.

Judging from the action of water on some of the pieces in the quarry, it might easily be concluded that a building of Weldon stone would always give free passage for moisture from without. It is evident, however, that some chemical or physical action occurs, through which the pores are effectually closed. How long it takes to accomplish this change was not revealed, and it is to be regretted that somebody was not present at the quarry who could talk about the stone with precision. Some of the remarks of Mr. THOMPSON at the luncheon might be easily interpreted as a warning against its general use, for he was emphatic about its porosity. We believe that if not used immediately after it is quarried, there is little danger of the stone being an aid to dampness. Besides, the absorbing power of a stone is not by itself the best test of strength, as is seen with sandstones, which disintegrate although they are not very absorbent. Weldon stone has weight and cohesive power, and the buildings where it was employed show its endurance. The colour is always pleasing, the stone can be got out in blocks of great size, and there is apparently remarkable uniformity in quality. If the quarries are conducted with prudence, there is a likelihood that the stone will be sought after, for it is said to be easily worked, and, with the aid of the Midland Railway system, it can be delivered at a reasonable rate in London or elsewhere. When it is known that

the profits are to be assigned to the restoration of Kirby Hall, every one who admires English architecture must wish that Lord WINCHILSEA will be successful in his experiment.

#### RHIND LECTURES IN ARCHÆOLOGY.

THE first in the series of Rhind Lectures in Archæology, Edinburgh, was delivered on Friday by Dr. Robert Munro, on the "Lake Dwellings of Europe."

Dr. Munro began with the geographical distribution and details of the remains of lake dwellings, dealing in particular with the stations discovered in Lake Zurich and Western Switzerland. He related how the first discovery of a lake dwelling had been made at Ober-Meilen, on Lake Zurich, in the winter of 1853-54, when some of the inhabitants, taking advantage of an exceptionally low state of the water to reclaim ground at the margin of the lake, came upon wooden piles, stone hatchets, stag-horns, and other remains. The discovery had not attracted much notice until the attention of Dr. Ferdinand Keller had been called to it, and an examination led him to the conclusion that these piles, systematically arranged, had formerly supported a platform, and that on this platform huts had been erected, which at a later period had been destroyed by fire. This discovery and the explanation of it led to other discoveries of the same kind in Lake Zurich, in the neighbouring lakes, and all over Europe; but in Lake Zurich it was the extraordinary activity of the people of Zurich itself which had led to the greatest discoveries. The ornamental quays, gardens, and promenades, begun about five years ago, by which they had completely transformed the shores in the immediate neighbourhood of the outlet of the river Lemat, had been filled up by materials dredged from other parts of the lake, and these operations had revealed lake settlements at Wollishofen, Kleinhafner, Banschanze, and other parts of the lake. In these remains of all ages had been discovered, most of all at Wollishofen, where, along with relics of the stone age, were brought up implements which showed that it had existed during the most flourishing period of the bronze age. Knives with ornamented handles, ornamented spear-heads, armlets, and ornamental dishes, all betokened a certain advancement among the inhabitants. Leaving Lake Zurich, Dr. Munro went westward, and dealt with the group of lakes, Neuchâtel, Bienne, and Morat. He related how attention had first been drawn to the subject of lake dwellings in the district by the discovery of a steinberg in Lake Bienne, covering three acres, and rising gradually from a depth of 20 feet to within 7 or 8 feet of the surface. Among these stones the heads of piles had been discovered, and examination showed that a lake dwelling had existed there, and was exceptionally rich in antiquities. A further search showed half a dozen settlements to have existed in Lake Bienne, and Government operations for lowering the level of the lakes in order to reclaim the delta of land between them brought to light numerous other dwellings. In Bienne sixteen were discovered; in Neuchâtel fifty or sixty, and the most interesting of these were noticed by the lecturer, and the most remarkable finds described and illustrated by diagrams. Similarly he described the settlements in Lake Geneva, fifty or sixty in number, and in several of the small western lakes. Speaking generally, he noted how the stations of the bronze age were further out from the shore than those of the stone period, and how the character of the implements as regards workmanship improved in the more westerly settlements. Comparatively few of the celts of Eastern Switzerland had a socket, and in the whole of the Wollishofen discoveries there was not a single knife with a socket, while in Western Switzerland the reverse was generally the case, and numerous objects were found tin-ornamented.

The second lecture was delivered by Dr. Munro on Monday afternoon. Beginning with the settlements of Robenhäusen, in Eastern Switzerland, he remarked that investigations had shown that these pile dwellings formed an irregular quadrangle a little over three acres in extent. The piles were of oak, beech, or pine, and it was calculated that 100,000 were required for the whole settlement. They were now several hundred yards from the present margin of the lake, and the remains were found under 5 or 6 feet of peat. There could be no doubt, however, that originally they were surrounded by water. The nearest land on the east side was 2,000 yards, and on the west side 3,000 yards; but notwithstanding that great distance, there extended a gangway from the settlement, the remains of which could yet be traced. This was one of the most famous settlements that had been discovered in connection with lacustrine research. It appeared from the testimony of the piles that the settlement had on two different occasions been destroyed by a conflagration, and of these there existed ample evidence in the charred remains of wood, food, cloth, and other articles. The settlement had been rebuilt after the second conflagration, and had evidently for some cause been aban-

doned—probably owing to the steady accumulation of the peat around it. From Robenhausen a large quantity of remains had been got, including a canoe, a yoke made of hazel branch, and an assortment of knives, clubs, stone axes, pottery, and a smelting clay crucible, in which traces of copper were found. The settlement of Niederweil was discovered, as was that just mentioned, by peasants cutting peat. The dwellings had been constructed on a series of artificial islands, and there were no evidences that they had been burnt. The pottery found was very curious. Some of the fragments were ornamented, others were neatly polished, and had handles of finished form.

A considerable portion of the lecture was devoted to a description of the settlements of Lake Constance, the sheltered bays of which seemed to have had a great attraction for the lake settlers. Those found now were mostly at the lower end of the lake. If they existed at the other end they had been covered up by the silt of the river. From the settlement at Wangen as much as 100 bushels of charred corn had from time to time been collected, and from the quantity of charred applecores that had been found it was evident that the inhabitants manufactured some kind of drink. Most of the settlements belonged to the stone age, but some came down to the bronze age. At Bodman, at the extreme end of the Uhdlingen See, specimens of glass ware had been found; and at Maurach as many as one thousand nephrite hatchets. At Schussenried, on the Foedersee, it was pointed out that the platforms were constructed like a fascine—between each transverse wooden layer there being a bed of clay. Here a substance like asphalt was found, which it was believed the lake dwellers made from birch bark and smeared on their vessels. The pottery was ornamented. The lake settlements in the Danubian basin were next referred to—Starnberg, Mondsee, Attersee, and Laibach. At Starnberg articles had been found which pointed to the fact that this settlement had existed from the stone age until early Christian times. At Mondsee pottery was found beautifully ornamented. Deep incisions had been cut in the sides of the vessels, and some white substance run into it. Here also was found a curious double fork or dagger not got elsewhere. The Laibach Moor, it was observed, comprised an area of about 85 English square miles. At one time it had been a beautiful sheet of water. The remains of lake settlements had been found in the peat. These included, in addition to the usual implements, a sort of crucible, and a mould for casting hatchet heads. There were also hooks for fastening cloth, and a kind of phantom minnow for catching pike. The most curious thing found was a curiously constructed piece of mechanism, about 32 inches in length, having valves and hinges in the centre. It was identified as resembling the traps found in North Germany with which fish otters were caught. But at Laibach no remains were found of fish otters, but about 140 skeletons of the beaver had been found, though there was no historical record that such animals had ever existed in this place. This ingenious piece of mechanism, however, was no doubt the beaver-trap of the old lake dwellers.

#### ROYAL SCOTTISH WATER-COLOUR SOCIETY.

THE first Exhibition of this Society since it was honoured with the title of "Royal" was opened to the public in the Institute Galleries, Sauchiehall Street, Glasgow, on Saturday, two hundred and eighty-three works having been hung. At the customary luncheon, held in connection with the Exhibition, Mr. Francis Powell, president, occupied the chair.

The President, after the usual loyal toasts, proposed "The Royal Academies of Art." All institutions of long standing, he said, were liable to err by opposition or indifference to change, and a slowness to recognise new movements. The vested interest of age and the continuance of thought in old channels delayed the acceptance of fresh conceptions, but it was essential that the Academies should be alert to every dawning phase of art. For art, to live, must be progressive. There was no standing still. History showed that when advance ceased, decline commenced; and, therefore, every sign of fresh vitality should be hailed with joy as a probable new era in art. At present the people mixing in the artistic world could not have failed to notice a change taking place in the ideas and scheme of work by the leading young painters and their followers, which was broadly designated the new French school, for the first seeds germinated and radiated from across the Channel. It was very much scoffed at by many, as were in years gone, first the pre-Raphaelite movement, and later the *Æsthetic* feeling. Yet, who could deny that from the advent of each of those developments of art, painting gained, receiving regenerated impulse and life? And such, he had no doubt, would be the result of the present departure. It seemed to be their duty to urge the Academies to encourage that outcome of budding thought, though it might not accord with the views of former practice.

Mr. Colin Hunter, A.R.A., responded on behalf of the Royal Academy.

Mr. W. D. Mackay, R.S.A., replying for the Royal Scottish Academy, said it was no sinecure to be a member of the Academy at present, and if one read all that was said about it, he would have a bad time indeed. During the past few weeks a great friend of his own had written a work entitled, "Every Man his own Art Critic." In that work—which was one of no ordinary ability—they were told that, although the Scottish Academy had not taken quite to the pompous vulgarity of the body to which Mr. Hunter belonged, it had outdone it in the imbecility of its aims. It was all very well for that author to indulge in swearing at large in this way, but it would be difficult for him to name any of the leading Scottish artists for half a century after the institution of the Academy who did not belong to it. One exception there was—he meant Milne Donald, of that city—but he died young, and he had no doubt he would have been recognised by the Academy had he lived a few years longer to reap the honour he well deserved. Of course, the Academy did not arrogate to itself the credit of having given birth to art in that country. It was the culminating point of a movement which had been going on for some time before its institution, and it was the outcome of a great deal of artistic ability which existed in the country. During the half-century succeeding its institution, the history of the Scottish Academy was very much the history of art in Scotland. For himself and the other members of that body present, he had to say that they were certainly alive to what the President had said about what was fit and good for one period not being fit and good for another. He had some hopes that they would be able to move on the lines he had suggested, and that they would be able to make their body representative not only of the art of Edinburgh, to which it was now very much confined, but of that of the whole of Scotland. In regard to the new phases of art which had come upon them, he thought, while they should certainly be alive to the importance of keeping their eyes open to all those movements, there was another aspect which was not quite as obvious. In art as in theology, there was that which was permanent and that which was transitory; and in an article on John Pettie he had seen it stated that the art of Scotland had done more than the art of any other country to keep up the connection with the great art of last century and the one before, which was surely no small thing. Consequently, whilst they were open to new influences, and striving some of them to open themselves to them even more, it was perhaps not a bad thing for them to move cautiously. Like the old mail-clad knights, the Academy had to move slowly, for it was invested with a Royal Charter; and although there was a possibility, of course, of something being done in the way of revising that document, it required to be gone about with great circumspection.

Mr. William McTaggart, R.S.A., in giving "The Glasgow Institute of the Fine Arts," observed that in listening to Mr. Mackay he thought that art in Glasgow, as in Edinburgh, was surrounded by great difficulties. Whether they called themselves new or old lights, or whatever name they assumed, art itself was eternal, and it had an undying romance which helped to keep them all with a sincere and healthy interest in it even if they had not a healthy understanding of what it meant. With that interest, they were gratified both to see the results produced by the new school, and to hear that Scotland had kept a closer alliance than even England with the great artists of the world. In travelling on the Continent, people had said to him, "Oh! you are a Scotsman—you come from the land of poetry and romance," and he had thought surely the fine arts had something to do and to say in the matter. But the troubles that surrounded them! Difficulties met them year after year; and they had uphill work in getting people to inspect collections of pictures, while their critics sometimes compared them to first, and at other times to second and third rate men, which was not intelligent at all. Of course, he supposed they must put the one against the other, and make the best of the result. The Institute, which had done and was doing good work, should endeavour to rival the Exhibition in getting together a collection of pictures to attract the public, for it had been demonstrated that the Scottish people, especially those of the west country, would turn out to such sights in thousands and in millions. The Institute, though entirely an exhibiting body, stood in the same relation to artists as the Academy, and it had distinctly more power to gather a fine collection of pictures—lines, he thought, on which it could do a great deal of good. Scotland suffered from her artists leaving her, but in this country no man was considered to be a great man until he became an Englishman. Until an artist became a Londoner he was only a provincial, and he was treated accordingly. Despite that, he hoped the Institute would do its best, and he thought there was a prospect that, in the future, men would be more content than they had been in the past to stay in Scotland, and to paint for the Scottish people. For he thought there was something contemptible in

an over-love of appreciation, just as there was something contemptible in an over-craving for commercial success. If the Institute prevented an exodus of the best men from the country, it would assuredly do a good work.

Mr. D. E. Outram, in replying, said the only difference between the Society and the Institute that he could think of was the framework of the Institute. It was not only different from the Society's, but from all other art societies, as far as he was aware. It was not like the Royal Academy or the Scottish Royal Academy, and such like, for they consisted entirely of artists. It was not like the Manchester or Liverpool Associations, for they were composed entirely of laymen. But Glasgow had the merit of originating an Institute composed both of artists and laymen. It was, therefore, of true Glasgow manufacture, and so bound to succeed like all their enterprises down to the great Exhibition. They thought this peculiar feature in their constitution showed the far-seeing intelligence of their founders. It united artists with laymen, and laymen with artists, and by this combination they brought the benefits of their various experience and respective talents to promoting the object they all had so much at heart. It surely was a mistake to suppose that laymen were one whit behind artists in their enthusiasm in the promotion of art. If that was the case, then how much better that they should be associated together in the same work! It surely would afford all the benefits that unity proverbially conferred. But besides this, laymen had wide associations. They could spread abroad the knowledge of art and of pictures better than artists, who would be thought trumpeting their own cause. Then they were generally men of some substance, who could give tangible proof of their zeal by buying pictures and showing them to their friends, who naturally followed their example. Then they were very often travellers to far countries, and so could import a knowledge of foreign art as interesting and beneficial to artists at home as foreign manufactures were to our manufacturers. This was just the benefit of international exhibitions, for art had no limits to its sphere, and it was the glory of artists to have no peculiar nationality. Their Academy was that of the world itself. The Exhibitions accordingly had been more than usually interesting. Artists from other cities had said to him, "This Exhibition is not like others; it is cosmopolitan." Surely it was the best policy for the sake of art, of artists and art, to make the Exhibitions as much so as possible. It was thus that the Institute was working its way quietly, independently—for the civic rulers gave it literally no assistance—and successfully. Its success, he thought, was proved by the splendid band of talented artists that Glasgow could boast of already, promising to make that city take the highest rank yet in the school of art. It would have done so already, he did not hesitate to say, if so many artists had not—should he say unpatriotically?—migrated to London. Should they make a Glasgow school so distinguished that they will be glad to come back again?

Mr. P. S. Dunn proposed "The Royal Scottish Society of Painters in Water-Colours."

The President, in replying, said that the honour conferred by Her Majesty on their Society, by placing them in rank with their London prototypes, was a distinction of which they were very proud. They should have to live up to this honour, and show by renewed energies that in painting as well as title they were worthy of such position. When he looked around the walls at the work of his *confrères* he felt that they had only to keep shoulder to shoulder with heartiness and oneness of purpose to raise their Society to the highest level. The burning question with water-colours had always been, "Will they fade?" He had often spoken on this subject on these occasions, because it was of paramount interest to the aquarellist and collector to know the truth, and he would not apologise for doing so again. Last week he received the Blue-book report of the Commission of experts appointed by Government to investigate the action of light on water-colours, which investigation, after two years' most exhaustive experiments, was now concluded. The result showed that the permanence of their charming art was in their own and the collector's hands—in the first place by the artist selecting his colours, and, in the second, by the purchaser keeping his drawings free from damp. There were twenty-two pigments, comprising six yellows, one orange, four reds, four blues, four greens, two browns, and one grey, which, when painted on Whatman's drawing paper, resisted in dry air, without the slightest change, the action of the direct sunshine during the two years of observation, which was a calculated equivalent to the bleaching powers of 480 years' ordinary daylight in a room. With these permanent colours and their combination they had an endless variety and scale of tints. Such being the case, no water-colourist need in future seek perishable material to produce the most luscious colouring, and the connoisseur might know in acquiring these works he was securing the most durable as well as the most beautiful description of the painter's art.

Other toasts, "The Guests," "The Chairman," and "The Croupiers" followed.

## TESSERÆ.

### Coloured Materials in Architecture.

A. H. CHURCH.

THE whole subject of the use of natural and artificial colour in architecture and sculpture is fraught with difficulty. We cannot, however, go far wrong if we interfere as little as possible with the picturesqueness of nature's chromatic arrangements whenever they possess a distinctive character; with uncoloured and less interesting marbles and stones, the case is certainly different. With pure white marble, having a slight translucency and a beautiful sub-crystalline texture, it often seems better not to interfere by any additions of artificial colouring. The substance appears so thoroughly fitted for the presentation of ideal forms that even the barest suggestion of realistic colour may look like sacrilege, and may easily lapse into vulgarity. This degradation is more particularly liable to occur when the sculpture is placed near the level of the eye and in a good but not very strong light. And here a curious effect of very powerful illumination and of a dim light may be noted. Strongly coloured surfaces are rendered pallid by brilliant sunshine, a clear atmosphere and a deep blue sky, reflecting under such circumstances an augmented proportion of white light. And when the light is dim, as in the interior of many an Eastern dwelling, the most decided colours lose their staring and obtrusive character, and merge into a harmony of darkened tones. In England we generally have to deal with the effects of a moderate degree of illumination, and in consequence we cannot reckon upon any considerable modification of the decided colours we may employ. In architectural interiors, where poor-looking or inferior materials (whether wood or stone) are employed, widely divergent opinions have been urged as to the mode in which artificial colour should be distributed. If the lines, contours, mouldings, and carvings are good, it is argued that they do not need accentuation with colour; if they are weak and poor, colour will but bring out their defects. And a scheme of artificial colouring, if quite independent of architectural forms, has the great drawback of breaking up the structural unity of the work. On the whole, it may be concluded that the only safe course is to arrange and calculate beforehand the scheme of form and colour as a united whole.

### Effect of Frost on Stone.

G. R. BURNELL.

The principal danger of exfoliation arises from the expansion of the moisture contained in the stone under the influence of frost, and a very elegant process was invented by M. Brard, for the purpose of ascertaining the probable extent due to this cause. M. Brard in his experiments upon the resistance of stones, caused them to be boiled for half an hour in a saturated solution of the sulphate of soda. They were then withdrawn and allowed to stand in a flat vessel, at the bottom of which was a small quantity of the same solution, the first efflorescences were washed off, and the degradation of the stones during the next five or six days, under the effects of the continued efflorescence, were taken as an indication of the probable extent to which they would be affected by frost. In the first volume of Rondelet's "Art de Bâtir," p. 307 (ed. 1842, Paris), M. Brard's process is described in detail; but some very curious experiments recorded in vol. 7, "1<sup>re</sup> serie des Annales des Ponts et Chaussées," by M. Minard, together with an article by M. Vicat, inserted in the same volume, throw very considerable doubts upon the exact amount of dependence to be placed on its indications. M. Vicat, indeed, very properly observes that it still remains to be proved that the expansive action of water in freezing is identical with that of crystallisation, which can only produce energetic effect at temperatures between 68° and 86° Fahr. According to this very accurate observer, stones which are exposed to a southerly aspect, on the north of the equator, are more affected by frost than those exposed to the north; and the most efficient protection to materials of this description of a porous nature is a coating of oil paint, or any other fatty pigment which prevents moisture from being driven or absorbed into the stone. M. Minard recommends that stone should be quarried in the spring, and not employed in a building until it has been exposed to the effects of one winter at least.

### Relation between Stained Glass and Architecture.

C. WINSTON.

It will be admitted, I apprehend, that the earlier Gothic styles are more severe in their architectural character than the later ones, and also that the glass most in harmony with Gothic buildings in the Norman or Early English styles is that of the twelfth and thirteenth centuries. I have tried for a long time past to discover the reason of this conformity, and have arrived at the conclusion that the harmony between the painted windows and the architecture depends far more on the colouring of the windows than on their design. I have often

contemplated the general effect of thirteenth-century, of fifteenth-century, and even of sixteenth-century painted glass in the windows of a Norman or Early English building, from a distance too great for admitting of my making out the design with any degree of distinctness, and have invariably observed that the colouring of the earlier glass most accorded with the character of the architecture, and that the harmony was the same, whether the windows were almost entirely formed of white glass, like the Five Sisters at York, or were richly coloured, as at Bourges or Canterbury. As might have been expected, I have not met with the same opportunities of contrasting the effect of thirteenth-century painted glass with that of the fifteenth or sixteenth century, in reference to its harmony with the architecture of the sixteenth century; but such experiments as I have been able to make have tended to create an impression on my mind, that the glass paintings of the fifteenth and sixteenth centuries do harmonise more completely with the character of the architecture of the fifteenth century than the glass paintings of the thirteenth. However, without pressing the last point, I will venture to express a firm belief that the colouring of a sixteenth-century glass painting does harmonise better with the character of a building in the Renaissance style than that of a thirteenth-century glass painting. In these conclusions I have been influenced by the general effect of the glass painting rather than by its force, because I have remarked that good cinquecento glass paintings, which are hardly, if at all, inferior in power to Early English ones, do not in general harmonise with thirteenth-century buildings so completely as the windows of the thirteenth century. The inference I draw from these experiments is that there is an analogy between the colouring of twelfth- and thirteenth-century windows, and buildings remarkable for the gravity and solemnity of their appearance.

#### Vasari's Biographies.

B. R. HAYDON.

It has occurred to me as a curious question, why Vasari's lives are sold throughout Europe better than any other painter's lives, and the reason is, they are not exclusively professional, though a whole code of technical practice can be ascertained from his occasional technical allusions, both on fresco and oil, execution and cartoons; but I will venture to say if these utilities had been their only merit, they would have lain unread, except by artists all over the world. Not so Vasari; he had more sense. Every man can read his lives and be amused, because he mixes up all the vices, virtues, follies, and tricks, characteristic of each artist. We know Michel Angelo, and Raphael, and Giulio Romano, and Titian, as well as if we had lived with them; he tells us all sorts of anecdotes of their private lives. Fuseli used to say to me, "What have we to do with their private lives?" I used to reply, "Everything." It is these touches of human character in every painter, the humour of Buffalmacco—the violent temper of Michel Angelo—the suavity of Raphael—that interests the unprofessional man, the general reader, and have kept Vasari the very Bible of painting, and ever will. Whereas in the lives of Fuseli, Lawrence, Reynolds, and Wilkie, each in succession is but a dry detail of professional correspondence, from which one retires harassed, disgusted, and sick; and after being published by a bookseller at a great expense, lie on our shelves after the first excitement, and are never referred to either for instruction or entertainment. Every painter's life could be made as delightful as a novel.

#### Old London Bridge Waterworks.

T. WICKSTEED.

In 1581 or 1582, Peter Morrys, a Dutchman, obtained a lease of the City of the first arch of London Bridge, on the north side, and erected a water-wheel, to be worked by the tide, and a set of force pumps to raise Thames water for the supply of the neighbourhood. The water was raised to the top of a wooden building 120 feet high, and passed from thence through pipes to supply the dwelling-houses in Thames Street, New Fish Street Hill, and Gracechurch Street, as far as a standard on Cornhill, which was erected in the middle of the street where the four ways meet. The water which was to spare, after supplying the beforenamed streets, flowed from the standard through four pipes branching to Bishopsgate, Aldgate, the Bridge, and Wallbrook, which supplied the dwelling-houses in the neighbourhood and cleansed the gutters in these streets. The site of the standard was supposed to be the highest ground in the City. The quantity of water raised was equal to about 3,170,000 imperial barrels per annum, or an average quantity of 216 gallons per minute, or about seven-eighths per cent. of the quantity raised by the waterworks for the supply of the metropolis at present. There were sixteen pumps worked by this wheel, each 7 inches diameter and 30 inches stroke. Mr. Smeaton ascertained from registers that the pumps made 3,025 strokes per tide; and, as there are 708 tides per annum (allowing one-fifth for loss through the valves, according to Dr. Desagulier's statements), the quantity raised may be calculated. Improvements, however, had been made before the

above particulars of the pumps were published, and therefore the quantity given will be the extreme probable quantity raised in 1582. In 1583 or 1584 machinery was fixed in the second arch. Improvements were made and the works continued in Morrys's family until 1701, when they were sold (after an engagement had been made with the City for a lease of the fourth arch) to Richard Soams, citizen and goldsmith, for 36,000*l.* Soams formed a company, and divided the property into 300 shares of 500*l.* each. In 1761 machinery was erected in the third arch; in 1767 machinery was erected in the fifth arch, and also in the second arch from the Surrey side for the supply of the Borough. The large wheel erected in the fifth arch by Mr. Smeaton was added in consequence of the reduction in the fall of water occasioned by enlarging the water-way under the bridge when two arches were thrown into one. And about this time an atmospheric engine was erected of 10-horse power to assist the wheels at neap tides, and as a safeguard in case of fire happening in the City at the turn of the tide, when the wheels, of course, could not work. In consequence of the City being obliged to pen up the water to work the wheels, according to an Act passed in 1756, in the twenty-ninth of George II., the blocking up of the arches became such a nuisance to the navigation of the Thames, that an Act was obtained in 1822, the third of George IV., for the removal of the London Bridge Waterworks, and they were removed accordingly, and the district was supplied by other companies, chiefly by the New River. At the time of the destruction of these works the number of tenants was 10,417, and the quantity of water raised by them was equal to 39,484,000 barrels per annum, or 2,704 gallons per minute; showing an increase equal to twelve times the quantity first raised in 1582 by Peter Morrys. In 1583 two conduits for Thames water were erected near to Old Fish Street Hill. In 1594, for the better supply of the City, Bevis Bulmar erected a large horse-engine and four pumps at Broken Wharf, to raise Thames water for the inhabitants of Cheapside, St. Paul's Churchyard, Fleet Street, &c., which, Maitland says, was removed previous to the date of his work, 1756, on account of other companies being able to supply water at a cheaper rate.

#### A Classification of Arts.

R. H. S. SMITH.

Among the objections that occur to the classifications of art commonly employed, whether historical, chronological, national, or other, is that they offer little explanation of the aberrations or inconsistencies of its development and very little of the analogies that are traceable in its efforts. I have therefore found it convenient to adopt in studying æsthetical questions a classification which corresponds to the broad divisions which have been suggested by ethnology. First, sensuous or instinctive art. Secondly, intellectual. Thirdly, moral or spiritual. A perfection appropriate and peculiar to each of these is capable of being attained apart from the others, but the combination of the whole, each in its own highest development, would be requisite to accomplish all that art is competent to reach; such a combination the world has not yet seen. The first division, that which I have named instinctive or sensuous, is the only art which exists among a vast portion of the human race—the whole of the first group into which ethnology divides man. The black races and the island people of the southern hemisphere do not attain any other art than this. A great portion also of the second group, the yellow and red races, do not rise above it. Respecting its characteristics and attainments I shall hereafter have occasion to enlarge. It is, therefore, only requisite now to observe that this instinctive art is not confined to certain groups of mankind. I may point to it among them, because it is the only art they possess. But it asserts itself among the nations who have proved capable of expressing themselves in the language which I venture to read as that of the two higher orders of art, intellectual and moral. The second division, distinguished as intellectual art, makes its appeal to human reason—to man's critical faculties; it forms its ideal from man. It summons the first class of art, sensuous or instinctive, to its aid, but rarely harmonises wholly with it. The perfection of intellectual art is to be found among the Greeks, who understood accurately and observed with subtle skill the faculties they desired to appeal to and the effect they sought to produce. All slavish reproductions of their art are therefore failures. The reproductions at Munich of Grecian temples turned into modern picture galleries are among the most notable examples of an error that arises from not fully comprehending what art is and the purpose it has to fulfil. A reproduction of any architectural work under different conditions of thought, life, climate, and use, is a solecism in art, and of necessity a failure. The third division is moral or spiritual art. The art which has its origin in man's noblest aspirations and makes its appeal to all that is highest in his nature. You may well believe that such art is rare. Its existence at all, the possibility even of its existence, implies that man looks higher than his own nature, that he has somewhat within him which is not satisfied with this earth alone. Painting, sculpture, and especially architec-

ture, afford examples of efforts at least made in the direction of this, our third and highest division of art. It also summons to its aid that which I have named sensuous or instinctive to supply fitting decoration, harmony, and splendour of colour, and in such combination this lower art may attain its perfection and yet be, as is just, in perfect subordination to the other. It also may, perhaps must, demand the aid of what I have characterised as intellectual art; the symmetry, completeness, and precision of this latter supply materials to complete the triumph that it could not itself obtain. The art that seeks to satisfy man's critical faculty only cannot reach his heart. In the ever-pending strife between emotion and reason, art is found enlisted sometimes on the one side sometimes on the other, but her greatest triumphs have been gained when reason has been satisfied, or nearly so, imagination aroused, and emotion stirred, but controlled.

#### The Mouldings of the Seven Periods.

E. SHARPE.

In the Norman period the mouldings are very simple and heavy, and placed at the corners of each of the orders of arches, but they are somewhat relieved and lightened in the doorways by zigzags, frets, &c.; still the round moulding prevails. I would observe that, notwithstanding this heaviness of appearance, the stones are not of greater depth than in any of the remaining periods, and the subordination I have described also prevailed throughout. I think an architect would therefore be inclined to say that the change of form which the arch gradually underwent was really by no means so important a change as a change in the mode of its construction would have been. The Norman orders were not heavier in regard to the size of the stones than those of the subsequent periods, and the workmanship of the Norman walls was, in reality, lighter than afterwards. In the Transitional period an increased lightness of effect is apparent in the mouldings, which assume a pointed form. We find also a peculiar form, which is of frequent occurrence in the Temple Church; we see still, however, the same general squareness of outline, for, though considerable portions of stone are cut away, the mouldings usually project to the angle of the stone. In the Lancet period the mouldings seldom or never come to the angle of the stone. There is a greater rotundity of appearance throughout. We have the tooth ornament between two rounds, the label moulding or hood moulding, and others peculiar to the period. In the Geometrical period the mouldings are distinguished by their elegance and minuteness. A common feature is the recurrence of little fillets, intersecting and combining with circular mouldings. You will observe the delicacy of these curves; and these, be it remembered, are in the doorways, for in the shrines, canopies, and smaller work, the mouldings are so minute and delicate, so light and elegant (many not  $\frac{1}{8}$ -inch broad), that one would scarcely conceive they could be executed in stone at all; yet, by the selection of a fine-grained stone, they were produced in the greatest profusion, and to an extent that we should now never think of imitating. And be it also remembered, these are not copies one of another, but original designs by men imbued with a general feeling, arising, perhaps, from education and habit, which is certainly capable of being identified. The mouldings are hardly ever copied; some particular group may be introduced from one subject to another, but they are generally slightly altered. In the later portion of this period, as at Guisborough, we have a continuous undulating form running through the whole series of mouldings. The orders begin to be larger; and later still, they increase considerably. Another circumstance also is perceptible, which is first seen in the Lancet period; that of placing the joints of the stones in a hollow. In the Transitional period (and of course in the Norman), that is never found to happen. Each order is there separately prepared, and one surface is placed against another, forming a right angle. In the later periods, the joints come in the hollows. In the Curvilinear period the hollows are broader and shallower, and the ogee form is one of constant occurrence. And I will notice here the gradual alteration of this form of moulding, which continually occurs in the Lancet period, and becomes modified in the manner shown. The double ogee first appears in the Curvilinear period, and is more common in the Rectilinear. Leaving the Curvilinear period, we find this flattening of the mouldings increased, as well as the breadth and shallowness of the hollows; and we have the three-centred hollow, corresponding with the four-centred arch; angularity of form in the label mouldings; with few or no mouldings of any projection; and I think we must admit that in the Rectilinear period the art of carving mouldings had very greatly degenerated.

#### The Vertical Line in Roman Architecture.

SIR G. WILKINSON.

It is universally admitted that the principal features which distinguish Greek from what may be called Church architecture are the horizontal line in the former and the vertical in the latter; and some have supposed that to church architecture is

to be ascribed the origin of the vertical line. That it is common to buildings of the Saracens, the Lombards, the Saxons, and the Normans, as well as to those of the Pointed style, is sufficiently obvious; thus far our experience tells us we have traced it, but beyond this conjecture has not attributed to it an existence, nor has its origin been ascribed to any more remote source. In the oldest Saracenic mosques, erected about the middle of the seventh century, the style of architecture is evidently borrowed from Roman buildings. Their arches are simply imitative of the Roman style; the windows, though small, have a round arched head; the corridors are formed of avenues of single slender columns supporting round arches, and the type of the Roman original is readily traced, as in the earliest churches of Europe, which also present the round arch of the Roman style. But in both these we find the lines already vertical; and that this might be expected from what we see in the monuments of ancient Rome is the point to which I wish particularly to advert. Those buildings erected by the Romans in imitation of the Greek, as temples, and some other monuments of a borrowed style, present the horizontal line of that architecture to which they really belonged, and of which they were copies; and, since we find this to be the case in all countries of modern Europe where Greek architecture is imitated (even though it is notorious that the vertical line is the prevailing feature of our taste) we cannot be surprised that the same should have been done by the architects of Rome. But whenever the Romans attempted any thing of their own, in which they thought a deviation from Greek models was allowable, we no longer perceive the horizontal, but the vertical line predominating; and to such an extent, that even a Greek entablature is sacrificed to this their favourite sentiment, being broken up into detached parts and compelled to project and recede, in order to allow the vertical line to pass continuously through it to the summit of the building. In an arch of triumph, a Roman composition, though the mouldings and many other details are borrowed from the Greek, the vertical line commences with the pedestal of the columns appended to its side, and extending upwards with the column, breaks through the entablature, which it obliges to come forward to carry out and mark its direction, requires a projection of the attic to correspond with the capital above the cornice, and terminates in a statue; thus continuing it uninterruptedly from the base of the summit of the building. This is not confined to an arch of triumph; the same occurs in other monuments, a remarkable instance of which may be cited in the remains of the Forum Palladium, or Forum of Nero (according to the Chevalier Bunsen), where the whole entablature is made to advance from the face of the wall to the distance of several feet, and is crowned by a similar projection of the attic, in order to correspond with the vertical line of the column which supports it; and the same taste for breaking up the horizontal line of Greek entablatures may be seen in numerous Roman buildings, the *ne plus ultra* of which occurs in the monstrosities of Petra. Thus then we find the vertical line did not originate with the architecture of Christian Europe; it occurs in the monuments of ancient Rome; and this interesting question naturally suggests itself, Whence did it proceed, was it of Italian origin? In the Rome of a Christian era the same occurs throughout its churches, which is the more remarkable as those churches are not of what has been termed Gothic, but of Greco-Roman or of Cinquecento style; and in these the vertical line extends from the lowest to the highest part. Even domes and cupolas are not exempt from its intrusion. It commences with the basement of the column, and, extending upwards through the projecting entablature and the attic, it continues in bands over the whole convex surface of the dome, requires a corresponding pilaster or half column in the lantern, and exhausts itself only in the extremity of the cross or whatever point terminates the building: a good example of which may be seen in the cupola of St. Peter's, whose façade—a memento of Bernini—not only unites the most glaring defects in taste but affords an illustration of the worst application of the vertical line. After viewing these monuments, and observing the feeling which pervades them, every one must be surprised at the sight of the splendid palazzi of Rome and other cities of Italy. In these we no longer perceive the vertical but the horizontal line predominating, which is carried out with wonderful effect, both in the rich and splendid cornices that crown the building and in the string-courses beneath the windows. In these no broken entablature injures the harmony of the straight line, no sinecure columns are suspended at the side of the walls to do nothing but spoil the effect of the whole mass; and we perceive that their architects did not put together a number of details to form a whole, but conceived the whole, and made the details accessory to the general effect. So evident indeed is this that the details are sometimes bad, and still the whole is excellent; as in many pictures of the great masters, where the composition and execution of the painting are of far greater importance, and far more striking to an artist than the imperfection of an accessory—like the sandal in the picture of Apelles.

## NOTES AND COMMENTS.

THE first decision of the Michaelmas sittings in the Court of Appeal related to a question of sale of house property. The Commissioners of Sewers purchased a house in Botolph Lane from the Drapers' Company, for the purpose of obtaining ground for widening the roadway, and paid 4,287*l.* for it. After a time it was found that the house could be spared, and the Drapers' Company claimed the right to repurchase. The Commissioners of Sewers agreed, but demanded 5,000*l.*, as the value of the house was said to be increased by the improvements in the neighbourhood. That theory was contested by the Drapers' Company, but the Recorder, in addressing the jury who tried the case, held that the additional value caused by improvements must be taken into account, and a verdict for 5,000*l.* was given. An application was made in a Divisional Court for a *certiorari* by the Drapers' Company but it was refused, and it was repeated in the Court of Appeal on Wednesday. Their lordships confirmed the decision of the Recorder. As a matter of justice, considered from a surveyor's point, and apart from technicalities, there can be no disputing the principle of the decision. The Drapers' Company exacted the highest price obtainable, and, having lost all interest in the house, the Company afterwards stood in the position of an ordinary individual, and therefore should pay the market price for the property under its new conditions.

THE Minister of Commerce has approved of the arrangements of the competitions for the diploma of the International Exhibition. The first will be general, the second will be restricted to five artists. The choice of subject is left to the designers, but allegory is allowable. A plain space is to be left for the inscription. The sketch designs are to be deposited in the Hôtel de Ville, Paris, before November 15. Five of the designs will be selected which are to be completed before February 1, 1889, and from them one will be selected, for which ten thousand francs will be paid. The four artists who were unsuccessful are to receive one thousand francs each.

At the present time it is not possible to see a large number of the pictures which are hung in some parts of the Musée Royal of Brussels. Several of the galleries containing examples of ancient pictures are covered by screens of white calico, which are not exhilarating to a visitor, and, somehow, the uncovered pictures seem to lose their value. The conservators are not, however, to blame. If the pictures are shrouded, it is with a view to their preservation. It is necessary to carry out some alterations in the sculpture gallery on the ground floor, and as the curators were of opinion that the dust might arise, and affect the paintings in the galleries above, it was determined to do something to preserve them. Hence the precautions, which are an eyesore to every visitor to the galleries. How long the pictures are to be concealed is a question which rests with the contractor.

M. GREBAUT, the successor of M. MASPÉRO in the direction of the museum of the Egyptian Government at Boulacq, is at present in Alexandria, where he is examining a sarcophagus which was lately found at Ramé, near Alexandria. It is supposed to contain the remains of ALEXANDER BALA, the Rhodian, who usurped the throne of Syria and dethroned DEMETRIUS SOLER about 150 years before the Christian era.

It is anticipated that Mr. WILLIAM JOHNSON, of Wandsworth, the contractor, may take an action against Mr. HELBY, one of the members of the London School Board, and against the printers of the Board, in respect of statements which have been published in the second volume of evidence given before the special committee on the work of the Works Department. The special committee propose that the School Board of London should undertake the defence on the understanding that an undertaking be given

by Mr. HELBY to repay to the Board all costs, charges, and expenses of every description in the event of malice being proved, and that an undertaking be also given by the printers to repay to the Board all costs, charges, and expenses of every description in the event of the action being lost by anything they may have done beyond printing the copies required by the Board.

It is once more necessary to undertake a restoration of the beautiful Fontaine des Innocents in Paris, although work of that kind was recently completed. People are beginning to find that the figures by JEAN GOUJON and PAJON cannot resist the atmosphere much longer. It is, therefore, proposed that the figures should be removed and placed in a museum, and substitutes provided, in the form of casts or copies in stone, erected instead. It cannot be supposed that the market folks will care much for the removal of sculpture.

THE Germans are pushing English traders very closely in Japan. In 1886 Great Britain imported 56,950 tons of rails and Germany 33,945. But last year, while the British trade was increased by no more than 7,500 tons, the German imports rose to 63,771—or nearly on an equality with the British. Rails are of very great importance in Japan. In 1886 Great Britain imported 37,409 tons, against 26,299 tons from Germany; while in 1887 Germany imported 35,222 tons and the English trade had fallen to 32,355 tons.

THE French Commission on the rebuilding of the Opera Comique have decided that the design is to be obtained by competition. This resolution was arrived at in spite of the influence of M. LOCKROY, the Minister of Public Instruction, who declared that it was unnecessary to seek for a design, since he had already presented one which was prepared by the Administration of Civil Buildings. At one time M. LOCKROY would have been the first to oppose such a proposition. It was also resolved at the meeting that a sum of 30,000 francs should be asked for in order to pay the expenses of the competition.

THE report of Vice-Consul PIETSCH on the timber trade of Memel during last year has not appeared until this month, when it is of little use as a guide to a timber merchant or builders. It is to be regretted that the Foreign Office will not take a hint from other countries, and recognise the importance of time as an element in business. M. PIETSCH is able to record an improvement in the timber trade of Memel. In 1887 the shipments amounted to 582,470*l.*, against 505,165*l.* in 1886. The report seems to indicate that the days for the use of Memel oak have departed in spite of the admiration for oak panelling. Odessa has now the trade. Business in oak beams is now of no importance, says the Vice-Consul. For the old stock carried over from former years 6*s.* to 7*s.* for crown, 10*s.* less for the second sort, was paid. The quantity brought down by the Russian dealers was quite insignificant, viz. 5,000 cubic feet, which fetched about one mark per foot. In oak wainscots no transactions took place worth mentioning. The competition of Odessa, from which port wainscots of the same quality as from Memel, with more suitable lengths, are shipped, is not to be overcome. The following prices were obtainable: 4*s.* for crown and 2*s.* 6*d.* for brack per running foot; for older stocks even these rates were not obtainable, and a considerable quantity still remained in stock. The new supplies consisted only of 1,040 reduced pieces per 18 running feet, against 3,662 in 1886. The trade in redwood and whitewood planks at Memel is also declining, owing to the competition of Sweden and Finland, and it is anticipated that the trade will soon be at an end. In red and white wood deals, on the contrary, a steady increase is observable. In former years, as planks were more in demand, merchants produced this article in large quantities, but now, the same being neglected and only to be sold with difficulty, they prefer the sawing of deals, the production of which pays well. The chief markets for deals are Germany and Holland.

THE REGISTRATION OF BIRTH.

ONE of the works by which Paris is represented in the Exhibition of Monumental Art at Brussels is "The Registration of Birth," which M. BLANCHON painted in co-operation with M. GERVEX. It was the theory of the artists that art should take the office of the historian, or rather of the journalist, and present scenes as they take place in reality, and hence they painted "The Registration of Birth," a ceremony which obtains more importance on the Continent than in England, as every male is expected to serve the State in the national army. Hence, also, the care which was taken in the picture to represent the fashions of the time, although it was known they were to be fleeting. The painting, too, suggests that, as regards registration and the subsequent calls which it involves on all citizens, the poor as the rich are on an equality.

## THE ARCHITECTURAL ASSOCIATION.

THE first ordinary meeting of the Association took place on Friday evening, Mr. H. D. Appleton, F.R.I.B.A., president, in the chair. Mr. Hippolyte Blanc, of Edinburgh, was elected a member by acclamation. The annual report and balance sheet, which are printed in the Brown-book, were, on the motion of Mr. Cole A. Adams, seconded by Mr. S. Flint Clarkson, unanimously adopted.

Mr. E. W. MOUNTFORD, hon. librarian, announced gifts to the library, and a vote of thanks was passed to the donors.

Mr. T. R. FARROW, hon. secretary, gave notice that a special visit, for members of the Class of Construction only, would be paid to the works of Messrs. Measures on November 3.

The PRESIDENT, after distributing the prizes, delivered an address.

## President's Address.

That the Association has become in reality "The College of Architecture," affording the best preparation for the candidates for the Institute Obligatory Examination, I think cannot be denied; and with this important object only in view it has a great future before it. But looking to the terms in which the founders of our Society defined its objects, namely, "To afford facilities for the study of civil architecture," "To advance the profession," "To serve as a medium of friendly communication between the members and others interested in the progress of the art," it seems to me that there are other subjects besides the examination which claim our attention; and with this in view, I propose to consider one or two suggestions for increasing the scope of our work.

With the present method of carrying on our work by means of honorary instructors, we can still include many studies which are not at present taken up; but I am well aware that the system has very definite limits and possibilities.

Instruction by visitors who teach at night what they are practising during the day, and handing on the information they gain, qualified by their experience in its application to actual work, is the most direct method of teaching that can possibly exist. And the sympathy between the visitors and the students is much greater, and the subjects treated much more practically appreciated, than is the case when the instructor is dealing with a subject in which he has not this practical experience in working out the facts or theories that he teaches. It is this feature in our system which is the greatest cause of the success of the Association. The visitors in most cases, being young practitioners, know the exact points where the students find difficulties, and having only recently acquired their knowledge, often from painful experience, are able to impart a very vital interest to their explanations.

The benefit to the visitors is equally great, as it stimulates them to qualify themselves for the position they occupy as directors of the studies of the younger members, by thoroughly working up the subjects they undertake. But the number of the older members who act as visitors must necessarily be small, and I am anxious to see the scope of the Association enlarged so as to bring in a great many more of the older men into touch and work with the present working members.

The time has now come, in my opinion, when a new departure should be made in the work of the Architectural Association, by the organisation of a division for the study of modern design. We have in our classes excellent opportunities for studying the classical or archaeological side of our art; but the modern side is only treated in the class of design, and I think that, taking the ages of the members of this class, it will be found that they are a younger set of men than used to form the class say ten or fifteen years ago, and I am afraid that it would be difficult to make the class work if any large influx of older men joined.

But as each year the tendency of modern design is to free itself more and more from the fetters of precedent which used formerly to bind it down to rigid accuracy, surely it is impossible to ignore altogether in the working of this Association the influence that contemporary work has on modern design.

As far as the prize list is concerned, the Association offers no encouragement for the study of contemporary design, but rigidly draws the line at the eighteenth century. No prize, as far as my memory serves me, has ever been offered by the Association for the study of any building of a later period. In this I think that the Association is quite right, and if it were proposed to substitute the study of modern instances for the study of old examples, I am quite certain it would be a mistake. A careful training in the purer styles of Classic and Gothic must in all cases be undertaken in order to train the eye to their just proportions, and to appreciate the beauty and appropriateness of their mouldings and features. And the only way in which this can be satisfactorily done is by carefully measuring and plotting and sketching the actual examples of old work. In fact, without the study of old examples, half our interest in the good modern work of our best architects would be lost, because it is only through our knowledge of old work that we can appreciate the excellence of the rendering of the styles in which they work, and the wonderful manner in which they succeed in catching the spirit of it, that spirit that gives their work most of its charm. This is the way, and the only way, a student can start on his studies. And, therefore, I think the Association rightly limits the period of the buildings to be studied by her travelling students to those erected prior to the eighteenth century.

But still we cannot shut our eyes to the fact that the precedents for design are sought in contemporary work, and, whether we like it or not, the practice is on the increase, owing, in a great measure, to the number of illustrations that are published. And, this being so, it becomes a question whether we should not honestly admit the fact, and do our best to train our powers of analysis and criticism so that the selection shall at least be of the best examples. It would not be difficult with many a modern design by our best architects to produce the old examples on which they were based. A careful comparison of the original with the translation would show how much the master mind had used of the original, and how much was his own, and the process of analysis could go further—the translation might be from an original stone or brick treatment into terra-cotta, and to trace how the master had handled the detail so as to suit the new material, and stamp at the same time his own personality on the work, would be most excellent study; or, in other ways, how the nineteenth-century requirements were made to modify the original expression. It might, then, be a useful exercise for us to take the old example and try our 'prentice hands at a similar translation. I think, then, we should all acknowledge that the experience gained by the study of how a master workman had handled the subject before us would be of the greatest use in our own attempt. What we want is a careful training in analysis, so that we can learn to know what is good and what is bad in modern design. Then the visits made to modern buildings would be greatly increased in instruction and interest. But this power of discrimination can only be the result of careful training, and students should certainly not attempt to study modern work until they have gone through a proper elementary course in the purer styles. I am anxious not to be misunderstood. I do not for a moment propose the study of modern work for our younger students, or to in any way take the place of a careful study of old work by measurement, or sketching, or the study of all the valuable literature connected with old examples. But what I do lay stress on is that the work that is going on around us, and which is so abundantly illustrated, cannot fail to have a vast influence on our own work. We have here principles of design and pleasing forms of art all ready to our hand, and we should be more than human if we were in all cases able to resist the temptation to taste and handle the forbidden fruit.

It is in order to settle the proper position which the study of contemporary work should occupy in the education of our young practitioners that I venture to make the following suggestions, namely, to form a modern side in the Association which shall be for those members who have passed through the present more or less archaeological studies; and the first step that should be taken for the formation of this should be the institution of a common room, open every evening, where all

the members might come in contact—the young students using it for a waiting-room till their classes were held, and the men of the modern division for those interchanges of views on professional topics commonly called “talking shop.” It should be with a view of talking shop that they should congregate.

Without having any formal papers read or forms of discussion, certain evenings a month might be set apart for talking over subjects previously agreed upon, such as, for instance, one evening a month might be devoted to discussing the illustrations published in the professional press. But I am anxious to avoid formulating any programme, because I want this to be a common room and nothing more, where a member might be sure of finding another member willing—aye, more than willing, eager to talk shop. I am a great believer in talking shop, circumstance and place being appropriate. Then, in connection with this modern division, we ought to have an annual exhibition of illustrations of buildings actually erected, not only in the United Kingdom but all over the world. This would not be difficult if photographs had, as I venture to suggest they should, a prominent position; but these photographs should be accompanied in all cases by sufficient working drawings to thoroughly explain the principles of design in the buildings. These illustrations should be arranged in such a manner as to contrast the buildings designed for similar purposes, and in such order that they may be intelligently studied and compared with one another. This exhibition could, I think, without very great difficulty, be made a much more complete exponent of our modern art than the architectural room at the Royal Academy at present is.

The object of this collection, as I would suggest, should be to show the profession what is being done at the present time, year by year, to meet the architectural requirements of the age. It may be urged that the professional press does this sufficiently fully to obviate the necessity of a special exhibition. I am perfectly ready to acknowledge the wonderful profusion and beauty of their illustrations, and, for the purposes for which I propose this exhibition, the mere arranging of these illustrations in due order would go far to meet the purposes for which I suggest it. The Royal Institute would, I venture to hope, co-operate with the Association to make this exhibition as comprehensive as possible. Whether the public would be induced to take an interest in it or not, I think, is of little consequence; I only propose it as an instruction to the profession; but with the increased interest that is being taken in architectural matters, I think it not at all unlikely that the public would in time be found to take it up. During the exhibition each section should form the subject of one evening's discussion, and, if possible, not only the designs but the material and points in the construction be taken into consideration. Again, the designs submitted for the great public competitions, such as the Admiralty and War Offices, the Liverpool Cathedral and the Imperial Institute, should each in turn also form the subject of discussion in this common room; difficulties in points of practice met with by any of the members could well be discussed, and good advice obtained; in short, everything of interest to the profession should be considered at one time or another by these friends in council. By this means I hope to form a definite professional opinion on the actual work that is being done, which may have an influence on the work of the individual member. This modern division should also form an excellent opportunity for those of our members who have passed the age when they can readily avail themselves of the classes, but who are anxious to prepare for the Obligatory Examination. This could be easily done by the formation of reading parties, in which a definite course of preparation for the examination could be arranged, which might include time sketch designing as a practice for the design day in the examination.

Ours is essentially a students' society, and the whole of the work (or nearly so) now done in it is for the benefit of those who are preparing themselves for independent practice; but I contend that the objects of this Association are by no means limited to this, and I believe that the free expression of opinion on questions of design and construction would be of very considerable educational value to everybody concerned. In these latter days, with the increased liberty in design, there is not a little tendency to license, and doubtless there would be plenty of doubtful examples for the censors to draw their moral lessons from, and thus curb the ardour of the younger men and lead them in the direction of more consistent styles. And the fact of pointing out these things would, I trust, have an equally good effect on the censors, who might reflect that some of their own work might come under like condemnation. I know of no place where similar opportunities for the exchange of professional opinion can be enjoyed on so large a scale as would be possible if this scheme were carried out; but the general idea has been carried on successfully in several small societies which exist among our members, and I am sanguine enough to hope that it would succeed on the larger scale.

Although the number of old members who continue their subscriptions long after they have ceased to derive any benefit

from it is a very gratifying feature, it has always been a matter of regret to me that the majority of our members so quickly drop out of touch with the working of it as soon as they have passed through the classes, and it would be a most important step in advance if those members would revive their interest in the work of the Association. The sacrifice of time need not be very alarming, say one evening a month, and no pledge given, but just to drop in for an hour or two, and in a friendly chat help forward the matter under discussion, or to express an opinion either of commendation or the reverse on what is public property and open for criticism. In this way I feel sure a large amount of good work could be done, and it would be a great help to our younger men to have some guidance in the formation of their opinions on questions of design. And if you had to listen to some crude talk or advanced opinion from the younger men, it would do you but little harm—nay, I make bold to say it might do you some good. Greater enthusiasm and earnestness of purpose, as far as my experience goes, are rarely to be met with than amongst our members, and the kind attention with which they always receive any endeavour to help them in their work more than repays any trouble it may involve.

But I have dwelt, I am afraid, too much on this attempt to reintroduce an old and most important feature of the Association in its early days, and will now only just refer to our scheme for the affiliation of all the Student Architectural Societies with our Association, as this subject will have to be brought before another ordinary meeting during this session, in accordance with the rules which were passed a short time ago. I may, however, be allowed to briefly mention the most important features in the scheme. The first is that, as, in accordance with the new charter of the Royal Institute of British Architects, this Association will have a recognised representative on the Council, this affiliation scheme will, if successfully carried out, constitute him the representative of all the architectural student members belonging to the affiliated societies; and in any matters connected with the Obligatory Examination it is most important that they should be directly represented on the Council. Secondly, as most of the classes carried on by these societies are modelled more or less directly on our own classes, valuable exchanges of information and advice can be made. In some cases the classes, as is now the case with the Birmingham Association, can make arrangements for interworking. And the repetition of some of our courses of lectures to the provincial societies, and the extension of the use of the loan library, are most important benefits that will be derived from the scheme.

With regard to the work of the Association classes, some slight alterations have been made in the elementary classes of design which were suggested in the class reports, and which it is hoped will improve and increase the benefits, already very great, which are to be derived from these classes.

No alteration will be made in the class of design, the result of the working of last session being considered satisfactory. But during the present session an attempt will be made to improve the working of those classes in which paper work is submitted. Under the present arrangement the visitors to these classes have to deal with some thirty to forty papers, each of which consists of fifteen to twenty pages of foolscap. The mere reading, correcting, and marking of these papers is no slight task, and to attempt to point out to each individual student the errors in his paper at the class meeting, or to question him as to answers which require explanation on his part, as well as to point out to the class specimens of the best answers is almost impossible, and makes the meetings very long and sometimes slightly tedious. Among the fresh facilities for study, it has been found desirable to start this year a class for the study of natural philosophy, which will form an introductory course to the class of graphic statics. The new course of lectures on geology has a very close connection with the science of building, and those students who make their first acquaintance with this most fascinating of all the sciences will find in Mr. Locke an able and lucid exponent, while those who already have some knowledge of the subject will, I venture to think, find it treated from a standpoint from which probably they have not previously regarded it, and both will, I hope and trust, be led to make practical geology one of their constant pursuits, as the opportunities which they as architects have of following up this study are very great. It is to be hoped that the students this session will not neglect their opportunities as they did last year with regard to joining the land-surveying class in sufficient numbers to enable the class to be formed. I would also call the especial attention of the members to the new arrangements for the study of water-colour, which should insure the success of the water-colour class during the vacation, and I will now conclude with a few remarks to those students who are about to work in the classes.

I take it for granted, gentlemen (and I am sure you do yourselves), that you are all greatly gifted and have each and every one a glorious and successful career before you; but of this much I am sure, that the matter is very much in your

own hands. Remember that the very magnitude of your talents implies great responsibilities, that genius is said to be only another word for capacity for hard work, and that it is only those who persevere and work to the end who really show and make good use of the talents they possess.

Year by year our class reports record a falling off in the attendances at the class meetings towards the end of the session. This can only be attributed to one cause, that the students are disappointed in themselves and find that they are not the geniuses they thought they were, or they would endure to the end. But I hope I am not speaking to any such to-night; and if I am, I would still urge those who feel this disappointment to work steadily on, because you may have been mistaken and find that your talents were hidden treasures, only to be found by painful search. In this Association every one is on a perfect equality, and your position in it will be entirely of your own making, and depend on your abilities and personal qualities, without regard to your rank, position, or money.

In working in the classes you cultivate habits of self-denial, unselfishness, self-reliance, and industry, which will make your life work easier, and in the end you will find these habits a very good substitute for genius. The prize can only be gained by one; the benefit of working in the class can be shared by all. By all means strive for the first place, but do not leave off working because you see you have no chance for it.

Cultivate by all possible means the artistic side of the profession, but do not be led into the error of despising the practical and constructive side. If, for instance, you have to leave the writing of your specification to some one else, I am afraid the building will hardly realise your own ideal. No artist was ever spoilt by studying construction, and as facilities are now afforded for you to know the why and wherefore of each formula you use, I would strongly urge you to follow up the study at least so far as to be able to build up some of the simpler formulæ for yourselves.

Take every opportunity the Association affords of making new acquaintances among your fellow-students; they may, and often do, ripen into useful and valuable friendships in after years; but my object in this is for present purposes. One of the most important accomplishments in an architect is to be a good judge of character, and in the Association you have as varied a collection of types as you are likely to meet anywhere.

I said at the commencement that our system of instruction had very definite limits and possibilities. The value of receiving tested and approved information is very great, but at the same time it is necessarily condensed and brief. Do not therefore think, when you have listened to all the lectures and passed through all the classes, that your salad days are ended, and in the ripeness of your powers you are equal to any emergency. The lectures and classes are at best only hints and outlines that you must fill in for yourselves.

In London the opportunities for doing this are without rival anywhere, and full particulars where these are to be found are set out at the end of the Brown Book. The classes are only intended to whet your appetite for more direct and scientific knowledge.

A vote of thanks, moved and put to the meeting by Mr. Aston Webb, having been seconded by Mr. John Slater, and supported by Mr. Tarver, Mr. Pink, Mr. Bulmer Booth, and Mr. Cole A. Adams, was unanimously passed to the President for his address.

#### GLASGOW ARCHITECTURAL ASSOCIATION.

AT the second sessional meeting of this Association a lecture was delivered by Professor T. Baldwin Brown, his subject being "The Art of Decoration." Mr. Thomas Gildard occupied the chair. Before proceeding to the business proper of the evening the Chairman referred to the recent death of Mr. Sellars, and the president, Mr. Keppie, moved that an expression of the Association's loss be minuted and a message of condolence forwarded to Mrs. Sellars and family. The motion was seconded by the vice-president, Mr. A. N. Paterson, and unanimously agreed to.

Professor Brown remarked that all true art was of necessity decorative. This was literally the case in Classical and Mediæval times, but, commencing with the Dutch *genre* painters in pictorial art, and with the sculptors of the Italian Renaissance in plastic art, a distinction had arisen between the "artist" (regarded as the painter of subject pictures) and the decorative handicraftsman—a distinction which had gone on increasing to the present day. That this distinction was little felt even in early Renaissance days the lecturer showed by recalling the fact that the greatest artists of that time, Botticelli, Ghirlandajo, Giotto, each kept his *bottega* or shop open to all comers. Returning to the beginnings of decorative art, the lecturer showed that it was really the natural outcome of joy

in life, the escape from gaunt necessity to freedom, or of the desire to do honour to God or hero. The practical accommodation of worshippers was only to the most limited extent the motive power in the designing of Greek temple or thirteenth-century cathedral—the two greatest creations that the decorative arts have given birth to. On the spontaneous and unreasoning sentiment, however, was soon engrafted the definite expression of particular ideas, and decoration became phonetic. This highest quality was very fully considered by the lecturer, who gave an interesting analysis of a notable example of expressive decoration—Michel Angelo's frescoes in the Sistine Chapel. An utter lack of this quality, expressiveness, was noted in most modern work, and an excellent illustration of this was furnished in the great collection of decorative designs forming the Queen's Jubilee presents. Yet these designs were called forth by an occasion which focused the history of the last fifty years and evoked sentiments of loyalty and thankfulness. With a reference to the principles of architecture, the mother art, all embracive, and therefore capable when known and acknowledged of duly regulating the relative values of the other arts, and, in particular, of regulating the decorative arts of to-day, the lecture terminated.

A vote of thanks was cordially awarded Professor Brown.

#### LIVERPOOL ARCHITECTURAL SOCIETY.

THE opening meeting of the forty-first session of this Society will take place on Monday evening, the 29th inst., when an address will be given by Mr. Edmund Kirby, A.R.I.B.A., the president.

Ordinary meetings will be held each month, on Monday evenings, at the Royal Institution. Papers have been promised by Sir James Picton, on "The Various Town Halls of Liverpool" (to be held at the Town Hall), and by Mr. James N. Schoolbred, on "Electricity." "Notes on Impressions of Architecture in the United States" will probably form the subject of another paper. The art congress will be held during the week beginning December 3. Papers in the architectural section will be contributed by well-known architects and others.

Arrangements are being made for holding an examination in Liverpool early next year. Mr. A. Culshaw, A.R.I.B.A., has consented to act as hon. secretary, and a class for preparation will be formed if justified by applications, which need not necessarily be confined to members of the Society.

The recommendation of the Council for federation with the R.I.B.A. is now before the Alliance Committee, and when the new by-laws are approved by the Privy Council, steps will be taken to complete this arrangement.

The Council report an increase in the number of members, the number now being 117, as compared with 108 at the close of last session. This number is made up of 42 Fellows, 32 professional Associates, 22 Associates, 20 students, and one honorary and corresponding member. There have been two resignations, viz., one Fellow and one Associate. The deaths of three members—Mr. Cornelius Sherlock (a Fellow), formerly vice-president; Mr. T. B. Crosse, of Shaw Hill, Chorley (a life member); and Mr. M. H. Bloxam, of Rugby (an honorary member)—are recorded with regret. Fifteen members have been elected, viz., three Fellows, eight professional Associates, three students, and one student from the professional Associate class.

In the class report it is stated that it has been the custom for some past years for the visitors to this class, on presenting their annual report, to express surprise at the want of interest taken by the main body of the students in these classes. The same want of interest still exists, although efforts have been made by individual members of the Society to induce the students to avail themselves of the advantages to be gained from advice in drawing and construction from the older members of the profession. Out of a total number of 20 student members of this Society, only seven have sent in designs, and four of these came from one office, that of our worthy President.

#### MANCHESTER ARCHITECTURAL ASSOCIATION.

THE session of this Association was opened on Tuesday evening by a conversation. Mr. A. H. Davies-Colley, A.R.I.B.A., the president, will deliver an address on November 6. Among the papers to be read during the session are the following:—"House Heating Water Fittings" and "House Cold Water Supply Fittings," by Mr. J. Corbett; "Treatment and Manipulation of Metal in Art Metalwork," by Mr. A. Standing; "Commission," by Mr. L. Booth; and also papers by Mr. J. A. Gotch and Mr. H. B. Bare.

In the annual report the committee, in reviewing the past

session, say they have again to congratulate the Association on the continuous increase of its ordinary membership, one honorary member and fourteen ordinary members having entered the Association; but they have to lament the death of an honorary member—Mr. T. Haselden, of Bolton, who had just joined. Two other honorary members have resigned, so that there is a decrease of two in this class, but in the ordinary members' roll there is a net increase of ten after allowing for removals, &c. The numbers now stand—honorary members, nine; ordinary members, sixty-four.

There were only three competitors in the Class of Design, and one in the Class of Construction. The committee feel disappointed at the year's work, but hope to see more energy and interest shown during the coming session, considering the great advantages the classes must offer to all students preparing for the Institute examinations.

Mr. John Ely, architect, Brazennose Street, in his report on the work, said:—

"I think that the competitors might benefit by the suggestion that if they do not study freehand drawing at a School of Art, they should lose no time in commencing to do so. In the drawings submitted there is evidence of the need of attention to this point."

Shortly before the commencement of the session a preparation class was formed for the examination in architecture of the Royal Institute of British Architects. The success of the class was such that of the six Manchester candidates in the examination, five were members of the class, and four passed. The committee were gratified by receiving the thanks of the Council of the R.I.B.A. for the excellent step taken in forming the class; and it was further stated that the Council had thereby been encouraged to hold the examination in Manchester. The committee suggest that the claims of Manchester to an annual local examination are worthy of the attention and consideration of the Council of the R.I.B.A.

In connection with the conversazione the work of members was exhibited in a collection of drawings and models. Examples of decorative art and furniture were also exhibited, and several local firms sent specimens of building materials. The Architectural Association also sent from London some well worked-out designs and sketches. In the course of the evening Mr. A. H. Colley, the president, delivered a short address explanatory of the work and objects of the Association. He congratulated the members upon the successful condition of the Association and the continuous increase in membership. The work, he thought, was exercising a good influence upon the architectural progress of the profession, and he anticipated the best results from it.

#### THE ROYAL SCOTTISH ACADEMY.

THE prizes won in the life school of the Royal Scottish Academy were presented to the successful students by Sir W. Fettes Douglas, president R.S.A., on Friday.

The President, in his address, said one of the best signs was that their school was so well and so conscientiously attended. The Council were exceedingly well satisfied with the whole of the drawings and studies. They had, however, some remarks to make which they hoped the students would take into their consideration. There was a school, a class or a clique, or whatever they might call it, who were studying blackness rather too much. Blackness and strength were by no means alike. In fact, blackness was a means of covering weakness in drawing and many other weaknesses: and the Council would be very glad indeed to see that the "black school" would give up its extreme devotion to its blackness. A little more taste and tact in the arrangement and in the touching in of the background would be a very great matter. There was not much background in a life school study, but the little there was might be done with consideration and taste. It was in knowing when a background should be soft or hard, and when to dispense with it altogether, that the true taste of the artist could be seen.

The Council would wish also to see a little more delicacy and clearness in the works not only of the "black school," but in those of the "delicate school," which was much more satisfactory to the Council's feelings. The black school seemed to be rather in the ascendant, and it really must be kept down—that was the short and the long of it. The Council had never interfered until this year, but they meant to put down their foot in this matter, and insist on having the black-and-white drawings more delicately and more thoroughly executed—in short, with less appearance of labour and with more true labour. He thought that the Council were better pleased with the studies in oil than with those in black and white. But he was not quite sure about that, for they were very pleased with both. In oil, the most thorough study in every respect was that to which they had given the prize. Mr. Marshall Brown studied very satisfactorily in almost every respect, and it was because of the thoroughness of his study that the prize had been given

to it. The young students had 'a great deal to learn in art; and he, perhaps, could not do better than tell them an old anecdote of what the three nationalities did when in want of food. The Englishman slept over it, the Irishman waked, and the Scot "gangs till he gets it." They had all a good deal to do in art, and he advised them to "gang till they got it." What he had said was very much the Council's view of the matter.

What he was now going to say was a very few words on art, and they were his own for good or for evil. In choosing the department of art they would permanently follow they would probably flounder about a good deal ere they settled into their several grooves; and this settlement would almost certainly be as much the outcome of their common sense, or the absence of it, as of their art power. He dared say very many men in every walk in life drifted into grooves they did not fit, and among the students who left their classes with a nearly equal amount of manipulative power those were to be congratulated who, through force of circumstances or mother-wit, quickly found themselves upon the course on which they were best fitted to run. The young artist who had lived in and mixed much in the lower stratum of society—perhaps been born in that stratum—when he became an accomplished manipulist sometimes thought that he took up a higher position in art if he painted society pictures than if he painted those who were not in society; but he would almost certainly fail, whatever his technical ability as an artist might be, for artistic power had no necessary connection with essential truth of character. On the other hand, if the young artist had been reared in nurseries, coddled by nurses, and trained by tutors, all carefully chosen as speaking fine English, he should stick to his natural platform and paint drawing-room scenes and other so-called society subjects. If he took to cottage scenes and low life, as he possibly might feel inclined to do—because of their, to him, unfamiliarity—he too would fail, and his cottage children, however exquisitely painted, would be absolutely without that essential fundamental character of truth which was the foundation of all that was most valuable in art. In saying this he wished to point out that the young artist, in choosing his walk in art, had much more than his brush power to consider. He must study his own idiosyncrasy—what his early life had been, and even what his parents had been. For the case might be summed up in one sentence. He who had been born a gentleman would never do justice in art to the gutter-blood, and yet more difficult would it be for the native-born gutter-blood to do justice to a gentleman. Thus, the most valuable knowledge the young artist could acquire was the knowledge of what he could and—more vital yet—could not do. Much of the non-fruit in after life of brilliant promise in youth was due to ignorance of, or an overweening confidence in, themselves. No man came into the world absolutely plastic, to be modelled into any chosen shape by himself or the world. He was handicapped from birth by transmitted ancestral tastes and tendencies, which he could not too anxiously study, and upon his judgment would depend his success in life. When he was a young artist, fifty years ago, the aspirant for a place on the Exhibition walls generally strove to take up very high ground indeed. He chose his subject from the sublimest parts of sacred and profane history, without considering for an instant whether the volume or characteristics of his mind or his educational training fitted him for his theme. Sometimes he condescended to the simpler scenes in Scripture, such as "St. John in the Wilderness," and generally was more successful with the skins in which the Baptist was clothed, than with the expression of the message he conveyed. But, after a time, common-sense and probably the claims of a dissatisfied stomach—for he never sold these pictures—led him to look out for, and paint, subjects more suited to his natural tastes and powers. Swift's anathemas on intending poets might well have been quoted to him:—

What reason can there be assign'd  
For this perverseness in the mind?  
Brutes find out where their talents lie:  
A bear will not attempt to fly;  
A founder'd horse will oft debate  
Before he tries a five-barr'd gate:  
But man we find the only creature  
Who, led by folly, combats nature;  
Who, when she loudly cries Forbear,  
With obstinacy fixes there,  
And where his genius least inclines  
Absurdly bends his whole designs.

They, the young artists of the present day, showed more common sense in the selection of what they desired to paint. They seldom chose a theme beyond their powers: but they were painfully modest, and never allowed the faintest gleam of fancy or imagination to illumine their canvases. What they did do was excellently done. Better painted life studies or water barrels were not anywhere to be found. But why should they not deal with subjects as well as objects? They might

probably justify their unfruitfulness of fancy by alleging the want of materials and models; but let them look around. There were materials everywhere, and models too. If they did not quite suit what they wished to do at the time, let them remember the French proverb—

When we cannot get what we like,  
We must try to like what we can get.

And while painting whatever came to hand, they need not lose sight of their natural and proper subjects. It was too much the tendency with artists, even the most accomplished artists, to look upon paint as the first element of good in a picture, and this was especially the case with young artists. But the painting of a great picture, however exquisite, was really but little more than the scaffolding of the monument. The monument itself depended upon the realisation by the artist of the true character of the people, the times, and the circumstances involved. If he did not grasp and mentally and morally feel these things, he might be said to understand paint, but he did not understand art.

#### KIRKSTALL ABBEY.

A LETTER has been addressed to the *Leeds Mercury* by Mr. G. Hill, the honorary secretary of the committee for the purchase of Kirkstall Abbey, in relation to the representations made to the Leeds Town Council by Mr. E. Wilson.

The following, he writes, are the facts. When it became known some three months ago that the abbey and grounds would shortly be offered for sale by auction, there was a widely-spread desire, indicated through the press and in other ways, that the estate should, if possible, be acquired for the town by private contract before the day of sale. But, so far as can be ascertained, no steps were taken by any one to secure that end. We therefore formed ourselves into a committee, with the sole object, as we explicitly stated in a letter which you kindly inserted in your pages on the 14th ult., "of purchasing the estate, with the view of its being subsequently acquired by the town, or settled under some other disinterested trust, under provisions that would secure the necessary steps being taken to stop the further destruction of the abbey, to provide for its protection and maintenance in the future, and to insure the dedication of the abbey and grounds to the use and enjoyment of the public for ever." The whole of the financial risks attendant upon such purchase we had determined to undertake. Our first step was to see Sir Edwin Gaunt, chairman of the Corporate Property Committee, to whom we made known our object frankly and fully. He congratulated us on our public spirit in taking up the matter, wished us complete success, and expressed his private opinion that the town council would regard our project favourably. At the same time he told us that about four or five years ago Mr. Edmund Wilson had brought before the Corporate Property Committee the desirability of Kirkstall Abbey and grounds being purchased for the town, and that Mr. Wilson had had some correspondence with the then agent to the trustees. Sir Edwin added that he believed Mr. Wilson had done nothing in the matter for two years or so, but suggested to us that it would be an act of courtesy to see Mr. Wilson before making any offer.

We therefore waited upon Mr. Wilson, ascertained from him that his negotiations had come to naught, and that nothing had been done by him for about two years. We laid before Mr. Wilson our whole project, and said we intended to offer for the abbey and grounds a sum not exceeding 5,000*l.* He expressed surprise on the mention of that amount, and, after being twice pressed to give his own notion of their value, named a sum much in excess of ours, or of what, under any circumstances, we should have offered, and spoke of forming a syndicate to purchase for the amount he had mentioned. Mr. Wilson then declared his intention to recommence negotiations, and desired us to leave the matter in his hands. We told him that if his object would be identical with ours we should be prepared to leave the matter in his hands, or would be glad if he would join our committee. He, however, gave us no information as to his object, nor did he accept the invitation to join the committee. Nevertheless, at his request, we agreed to stay our operations for a week, upon his undertaking to communicate to us within that time the results of his efforts. At the end of a week we received from Mr. Wilson a letter, dated September 4, wherein he stated that on that day he had had a "satisfactory interview" with the agent; but he made no mention of having done anything to secure the abbey and grounds in the public interest. On September 5 we wrote and delivered to Mr. Wilson a letter stating that his communication was so "completely indefinite," so far as our object was concerned, that we had determined to resume our efforts at once. On the following day we ascertained that Mr. Wilson's interview took place, not on the 4th, as stated in his letter, but on the evening of the 5th—that is, a few hours after the receipt of

our second letter, and that then, although he knew we intended to offer not more than 5,000*l.*, he made an offer of 5,500*l.*

After these experiences it was impossible for us to believe that Mr. Wilson's object was identical with ours. Consequently, and after learning that there was not the least likelihood of the estate being withdrawn from the risks of a sale by auction for less than 6,000*l.*, we offered that sum, subject to conditions that would have secured the preservation of the fabric, and the keeping open of the abbey and grounds for the use and enjoyment of the public, for at least three hundred years. As Mr. Wilson had no special authority to purchase for the town, as his former negotiations came to naught, as he had done nothing during the past two years, and as he bid over our heads, it will be seen that any competition against the public interest came from Mr. Wilson, or from Mr. Wilson and his syndicate, and not from the members of this committee, whom he has gratuitously and unjustly aspersed.

#### REGISTRATION OF ARCHITECTS.

IN the last number to hand of the *Building and Engineering Journal* of Australia and New Zealand we find the following note:—

Architecture is unquestionably one of the learned professions, and it has long been a distinct anomaly that civil engineering, which is really an offshoot from architecture, should receive University recognition, and the right, legitimately, to use the letters C.E., which are valued accordingly, while the parent profession is not officially recognised in any way. The Melbourne architects lately took a step in the direction of sweeping away this injustice, and an influential deputation of the leading architects recently waited on the University Council with a view to get a Chair of Architecture established. If this were accomplished no doubt the granting of a diploma or degree in architecture would follow, and that in time would weed out a number of very undesirable "brethren" who are no great credit to the architect fraternity. But even were such a chair already established, the "weeding-out" process would take a long time, and the present want may be much more quickly satisfied by the provision of a registration bill, which, if properly framed, would be an immense boon to every genuine architect in the colony. This matter again came up before the Institute in the course of an able paper, by Mr. Inskip, on "Architectural Education." His views are to some extent embodied in the proposed measure for the creation of a "General Council of Architectural Education and Registration." The unfortunate and acrimonious differences which have arisen among the architects in England over this question of registration has been happily wanting here, thanks to the strong good sense of the members of the profession, but we confess that we quite fail to see on what possible grounds the London R.I.B.A. oppose a scheme which cannot but do good in greatly raising the status of the profession in every part of the United Kingdom.

#### CHURCH BUILDING AND RESTORATION.

**Bolton.**—The Methodist chapel in Chalfont Street, built by Mr. R. Davies, contractor, Shaw Street, from the designs of Messrs. Lomax & Lomax, of Fold Street, to accommodate 400 persons, has been opened.

**Colinton.**—A small Episcopal church is to be erected in this suburb of Edinburgh. The building as designed by Dr. R. Rowand Anderson will be in late Gothic style. The plans show a small building, the chief architectural adornment of which is a square tower on its south side. Internally the church is divided into a nave, 45 feet long by 20 feet 6 inches in breadth, and a chancel, 20 feet by 14 feet, accommodation being thus provided for about 200 people.

**Norton Cams.**—The parish church, which was the scene of a fire early in the year, has now been reopened after enlargement and improvements carried out by Messrs. Treasures & Son, of Shrewsbury, from the plans and under the supervision of Messrs. Osborn & Reading, architects, of Birmingham, in the late Decorated style. An aisle, transept, organ chamber, and vestry have been added, and a baptistery formed under the west tower, opening into the nave by an archway. The church is built of Hollington stone. The roofs are open-timbered, and covered with dark-red Staffordshire tiles.

**Newcastle-on-Tyne.**—The church in Osborne Road, which has been in course of erection from the designs of Mr. T. R. Spence, of Rathbone Place, London, has been opened. Mr. Gray, of Gosforth, was the general contractor. Mr. John Dodds, assisted by Mr. W. Pringle, acted as clerk of works. The cost of the church, which has been defrayed by Mr. Charles Mitchell, has not been made public.

**Bungay.**—The restoration of the tower of the parish church of St. Cross, near Bungay, has been completed. The work has been executed under the supervision of Mr. E. F. Bisshopp, architect and diocesan surveyor, by Messrs. R. Stone & Son, builders, of St. Cross, with Mr. Perfitt, of Harleston, as mason. The new reredos and altar table, also executed from Mr. Bisshopp's designs, are the gift of the sister of the late rector, and executed by Mr. Godbold, of Harleston.

### NEW BUILDINGS.

**Oldham.**—The Austerlands Store, which has been erected from the designs of Mr. Alexander Banks, of Oldham, has been opened. On the ground floor are grocer's shop, 29 feet 6 inches by 22 feet; flour room, 22 feet by 14 feet; butcher's shop, 14 feet 6 inches by 13 feet, and covered passage. The grocer's shop is fitted up with counters, shelving, sugar-bins, and other adjuncts necessary for the carrying on of an extensive business, while the flour-room is replete with flour and grain bins. The butcher's shop is lined to a height of 7 feet with tiling, finished with a dado, the walls above being lined with pressed bricks. Between the covered passage and grocer's shop are the steps leading to the news-room, which measures 20 feet by 14 feet 6 inches. On the first floor, also, is a large store-room for the storage of flour and grain. In the basement are heating chamber and cellar, the floor above the former being fireproofed. The building externally is faced with local hammer-dressed stone, relief being afforded by ashlar dressings, the roofs being slated with Welsh slates, capped with Ruabon ridge tile. The floors are carried by rolled iron girders, upon which rest wood sleepers, supporting plank flooring, the whole constituting a strong floor capable of sustaining an enormous weight. The contract for the erection of the building was let to Messrs. J. & J. Whitehead, Oldham, the fittings being supplied by Messrs. Collins & Barrett, Lees.

**Blackburn.**—Improvements have lately been carried out at the Blackburn Infirmary, in the course of which special attention has been paid to the children's ward. Mr. Christopher Dixon is the contractor, and Mr. Angelo W. R. Simpson, of Blackburn, the architect.

### GENERAL.

**Mr. Edmund Law** was reappointed County Surveyor at the meeting of the Northamptonshire County Magistrates last week.

**The Late Mr. Owston**, of Goole, formerly chairman of the Humber Steam Shipping Company, has bequeathed 300*l.* for a peal of bells for St. John's Church in that town, provided a like sum is subscribed within two years after his death.

**Mr. E. J. Poynter, R.A.**, has been mentioned as a probable successor of Sir John Gilbert as president of the Royal Water-colour Society.

**Mr. E. Wareham Harry** has accepted the appointment of Surveyor of the Borough of Cambridge, and has resigned a similar appointment in Harrogate.

**Mr. J. H. Burton**, of Ashton-under-Lyne, has been successful in a limited competition for designs for a manse at Knutsford for the Congregational minister.

**Mr. Edgar H. Selby, A.R.I.B.A.**, on Saturday last, the 20th inst., delivered a lecture at Lewisham on "Some of the Northern Cities of Italy." The paper was particularly interesting, being illustrated by numerous original drawings.

**Rev. Brooke Lambert**, vicar of Greenwich, on Monday evening distributed the prizes to the students of the science and art classes at Tamworth. In the course of his address he compared the architecture of the present time with past ages. Present day architecture was, he said, merely copies of that of the Greeks. English architecture he described as being without beauty. The only building he knew of in England of real architectural beauty was the Houses of Parliament, and that was not absolutely perfect.

**It is Proposed** to rebuild the Brunswick Chapel at Whitby, at a cost of 4,000*l.*

**Reyton Church, Oldham**, is to be rebuilt at an estimated outlay of 5,513*l.* The new church is to contain 730 sittings.

**At the Glasgow Exhibition** the gate-money up to Saturday last amounted to 193,312*l.* 14*s.*, the total of admissions since the opening day being 4,929,788.

**The Eye Infirmary** which has been erected at Wolverhampton, at a cost of 8,000*l.*, was opened by Lord Dartmouth on Tuesday.

**A Silver Casket** with an address is to be presented to Mr. Thomson Paton, in recognition of his gift of a town hall and library to the burgh of Alloa.

**Preliminary Plans** for the Kendray Fever Hospital, proposed to be built by Mrs. Lambert of Barnsley, prepared by Messrs. Morley & Woodhouse, architects, were on Tuesday sanctioned by the Barnsley Local Board, and finished plans will be proceeded with.

**An Anonymous Donor** has offered to give 5,000*l.* for the building of a free library at Brechin.

**A Theatre** is proposed to be built on the site of the Temple Club.

**The Death**, at the age of thirty-one, is announced of Mr. Donald Mitchell, at San Francisco, on Monday. He left Pitlochry—nearly all the villas and buildings erected there and in the town and district within the last ten years were designed by him—to practise in California about a year ago.

**The Marble Statue** of the late Lord Iddesleigh, by Mr. Boehm, R.A., will be unveiled by Lord Cranbrook in the centre hall of the Houses of Parliament on the morning of November 6.

**The Architects and Surveyors' Assistants** in Melbourne have decided to establish a society under the title of "The Architectural and Engineering Association."

**At Ross Cathedral**, Fortrose, the north wall, it is said, is in danger of falling, and the authorities, who have taken charge of it as an ancient monument, have as yet taken no remedial steps, though the matter has been repeatedly reported to them.

**The Gloucester Town Council**, on Tuesday, adopted a resolution expressing regret at the death of Mr. Gambier Parry. A letter received from the bishop and the cathedral authorities was also read, stating the steps which were being taken to raise a memorial to Mr. Parry, and asking the co-operation of the Corporation.

**The Ancient Church of St. Mary's-in-the-Castle**, Dover, is being thoroughly restored and renovated by the Ecclesiastical Commissioners.

**The Institution of Civil Engineers.**—There are now on the books of this Society 1,614 members, 2,499 associate members, 458 associates, 19 honorary members, and 939 students, together 5,529, being an increase at the rate of 3½ per cent. during the past twelve months.

**The Lease** of the Theatre Royal in Manchester is drawing to a close, and a scheme is in contemplation to build a new theatre of most elaborate design in the immediate vicinity.

**A Proposal**, which it is asserted is likely to take practical shape, has been made for providing close to Westminster Abbey a "Campo Santo" for the sepulchres and memorials of departed worthies.

**A Meeting** of manufacturers and employers of labour in Dublin is to be convened to ascertain to what extent a guarantee fund would be anticipated, and to discuss the prospects of successfully holding an international exhibition in Dublin next year.

**The Death** is announced of Mr. E. W. Wright, at the age of sixty-four, who has practised as an architect at Adelaide, New South Wales, since 1848. He designed the town hall, the post-office, several of the banks, and other institutions, was President of the Association of Architects, and had been Mayor of Adelaide.

**A Conversazione** and sale of Christmas cards and sketches by present and past students of the Royal Female School of Art, Bloomsbury, will be held on Monday evening next. The proceeds will be devoted to the building fund for the new studio.

**The Parish Church** of Norton Canes, near Cannock (which was destroyed by fire some time back) has been restored from the designs of Messrs. Osborn & Reading, of Birmingham, and reopened on Monday, October 22. The reredos, pulpit, font, lighting apparatus, and the whole of the church furniture were supplied by Jones & Willis, of Birmingham and London.

**At the Italian Exhibition** in London the pictures and sculpture and other objects of interest in the main building and fine-art annexes are most numerous, numbering nearly one thousand five hundred exhibits, and their inspection fills up a large part of a day's holiday. The Roman Forum, Borghese Gardens, and Capri Grotto all invite attention, whilst the show in the Roman Coliseum forms one of the chief attractions of an afternoon and evening. The grand march past, at the conclusion of the sports, of the Vestal Guards, Roman Guards, Etruscan Guards, Imperial Guards, lictors, senators, consuls, priests, &c., embraces 500 performers.

**CRIMINAL PROCEEDINGS**, under the new Merchandise Act, will be instituted against any person falsely representing any form of ventilator to be a Self-acting Air-pump Ventilator, said title being registered and our Trade-Mark, applicable only to ventilators manufactured by us. Any infringement renders the person infringing liable to two years' imprisonment. ROBERT BOYLE & SON, LD.

### EDITORIAL NOTICES.

*The authors of signed articles and papers read in public must necessarily be held responsible for their contents.*

*No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.*

*Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.*

### TENDERS ETC.

As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 p.m. on Thursdays.

Correspondents, when writing to notify an extension of time, or an alteration of the date of sending in Competitions or Contracts, are requested in their letter of advice to write at the head of the required change—"Contract Reporter to THE ARCHITECT."

### NOTICE TO THE PUBLIC.

By the Post Office arrangements THE ARCHITECT can now be sent to any part of the United Kingdom by an affixed Halfpenny stamp; hitherto the postage has very frequently been twopence per copy. The Publishers will be happy to forward, for 20s. per annum, post paid, THE ARCHITECT, to residents in towns and neighbourhoods to which there is no easy access by railway. Terms for the half-year, 10s.

Our readers are invited to address us on subjects of interest to themselves or the public. We shall be always ready to insert letters asking for a solution of any suitable questions to a professional or practical nature, and to receive replies of such inquiries.

### CONTRACTS OPEN.

BISHOP'S CASTLE.—Oct. 27.—For Construction of Water-works in the Borough. Mr. Aaron Hamar, Borough Surveyor, Bishop's Castle.

BRADFORD.—Nov. 5.—For Completion of Six Houses, Horton Road. Mr. Samuel Jackson, Architect, 33 Kirkgate, Bradford.

BRADFORD.—Nov. 3.—For Building Weaving Shed, Westbrook Mills. Mr. John Drake, Architect, Winterbank, Queensbury.

CAMBERWELL.—Oct. 31.—For Extension of Infirmary, Havil Street, for the Guardians. Mr. R. P. Whellock, Architect, 45 Finsbury Pavement, E.C.

CARDIFF.—Oct. 29.—For Erection of Banking Premises and Office Buildings, St. Mary Street. Messrs. Jacobs & Pickwell, 65 St. Mary Street, Cardiff.

CORK.—Oct. 29.—For Enlarging Lea View House. Mr. W. H. Hill, Architect, 15 Marlborough Street, Cork.

DEVONPORT.—Oct. 29.—For Building Board School. Mr. J. P. Goldsmith, School Board Offices, Ker Street, Devonport.

FOREST HILL.—For Completing Four Houses, Colfe Road. Mr. W. Beecroft, 14 Billingsgate Market, E.C.

HASWELL.—Oct. 27.—For Building Manager's House and Shop. Mr. H. Hind, Secretary, Co-operative Provision Society, Haswell.

KENSAL TOWN.—Nov. 9.—For Building Public Library. Messrs. Harslake & Mortimer, Architects, 5 Great Queen Street, Westminster.

LAVENDER HILL.—Nov. 1.—For Building Central Library. Mr. E. W. Mountford, Architect, 22 Buckingham Street, Strand.

LEEDS.—Oct. 29.—For Enlarging Board School. Mr. Lee Clerk to the Board.

MORTLAKE.—Oct. 30.—For Building Hospital and Mortuary adjoining Cemetery. Mr. Alfred J. Wood, 17 The Green, Richmond, Surrey.

MOUNTAIN ASH.—Oct. 29.—For Adding Vestry, &c., to Chapel. Rev. T. Anthony, Gordon Villa, Mountain Ash.

RASTRICK.—Oct. 31.—For Building Chimney (45 yards), Badger Hill Mills. Mr. R. F. Rogerson, Architect, 11 Church Street, Brighouse.

SMALLBRIDGE.—For Building Premises. Mr. T. Butterworth, Architect, Miraflores Terrace, Littleborough.

SOUTHAMPTON.—Nov. 12.—For Partial Reconstruction and Reseating of Above Bar Congregational Church. Mr. W. H. Mitchell, Architect, 8 Portland Street, Southampton.

SOWERBY BRIDGE.—Oct. 27.—For Pulling Down Scar Head Mill and Building Eight Houses. Mr. S. Wilkinson, Architect, Sowerby Bridge.

STOKE-ON-TRENT.—Oct. 29.—For Alterations and Additions to Penkull Schools. Messrs. Scrivener & Sons, Architects, Howard Place, Hanley.

WIDNES.—Oct. 31.—For Erection of Strong-room at Town Hall. Messrs. F. & G. Holme, Architects, Crosshall Street, Liverpool.

INTERNATIONAL HEALTH AND OTHER EXHIBITIONS—MEDALS AWARDED FOR

## LEGGOTT'S PATENT ADJUSTMENT

CONTINUOUS OPENER.

SILENS.

THE SILENS, for Fanlights, Skylights, &c. Is admitted to be the best ever put before the Public. Can be adapted to any kind of window. Size and height of window no object.

From 4/3 each.

The WILMOS is worked with a rod or endless cord. It is extremely neat, and can be fixed to open either top or bottom, inwards or outwards; no cutting away of frame required. When worked with a rod is most efficient for Public Buildings, as the key can be loose. For Price Lists, Illustrations, and Testimonials, write as below.

For Continuous and other Lights, Estimates given.

WILMOS.

NO CUTTING AWAY OF FRAME REQUIRED.

## TESTIMONIAL.

SIRS,—I have pleasure in testifying that I have used Leggott's Silens Adjustments for various buildings to high skylights, fanlights, and top parts of windows, and in every case they gave satisfaction.

They are secure in whatever position, whether the window is open or closed, and are quite simple and workable in their action. I prefer them to any other that I have seen or used for the above-mentioned purposes.

Messrs. W. &amp; R. LEGGOTT, Bradford.

I remain, yours obediently,

R. DAVIES Architect.

Considerably Reduced Price List, November 1, 1887.

ALL WORK ENTRUSTED TO US GUARANTEED SATISFACTORY.

## TRADE NOTES.

A WROUGHT-IRON screen, of fine workmanship and design, an elaborately carved altar-table and super altar in oak and ebony, clergy desk and seats, executed from the designs of Mr. Hammond, architect, Circus Place, E.C., has just been completed and fixed at St. Giles's Church, Cripplegate, by Messrs. Jones & Willis, of London and Birmingham.

A LARGE clock and set of carillon machinery have just been erected at the new church, Peel, Isle of Man, by Messrs. John Smith & Sons, Midland Clock Works, Derby. The Cambridge quarters are chimed upon four bells, the hours struck upon the largest bell, and the carillon machine plays seven times upon eight bells, one tune for each day of the week. The clock is of the finest construction in every way, and has been carried out by the makers to the designs of Lord Grimthorpe. It has a double three-legged gravity escapement and compensated pendulum. All the wheels are of gun-metal with the teeth cut from the solid special apparatus as provided to keep the clock going while the weights are wound up, the weights are carried by steel wire ropes. The clock and chimes will doubtless be a great boon to the inhabitants of the

neighbourhood, for it is the most complete in the Isle of Man.

THE Preston Town Council, on Friday, decided to promote a Parliamentary Bill for powers to borrow money for dredging the Ribble, for plant for completing the dock and works, and for constructing a graving dock.

At the meeting of the Metropolitan Board of Works, on Friday, it was agreed that, after the expiration of Messrs. Mowlem & Co.'s contract for the maintenance of Westminster Bridge, in December next, the roadway of the bridge should be paved with wooden blocks; the engineer instructed to prepare plans and a specification of the work; advertisements issued on November 15 inviting tenders for the same; and the tenders to be opened at the meeting of the Board on December 14.

THE Eastern and Midlands Railway Company are surveying at Spalding for the purpose of constructing a new loop line to connect the line from Lynn to Spalding with the Bourn and Peterborough lines. The scheme, if carried out, would involve a new bridge over the River Welland, and the outlay would be over 30,000*l*.

THE award in an arbitration between the Wakefield Corporation and the Sandal Local Board was published on Monday. The Corporation claimed 39,000*l*. from the Sandal Local Board for the pipes, fittings, and other apparatus connected with the supply of water in the Sandal district, and the Local Board offered 1,010*l*. Mr. Cousens has awarded 1,345*l*., and the cost of the award, 197*l*. 4*s*. 2*d*., is to be paid in equal moieties between the Corporation and the Local Board.

MESSRS. KAYE & SONS, of Leeds and London, have just received instructions to fix their push-and-pull locks on all the doors in the new town-hall at Dewsbury.

CONSIDERABLE additions have been made to the College, Eastbourne, and special attention has been paid to the ventilation, the latest improved form of Messrs. Robert Boyle & Son's patent self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

THE valuation of Paisley was reported by the town clerks in their return on Monday at 259,259*l*. 11*s*. 7*d*. as compared with 250,505*l*. 15*s*. 4*d*. last year, showing an increase of 8,753*l*. 16*s*. 3*d*.

THE first annual public meeting in connection with the Coventry Technical Institute was held on Tuesday night, at

St. Mary's Hall. Lord Leigh, who presided, remarked that he felt a tinge of regret that the old Coventry Institute, over which he presided forty-one years ago, might now be said to be defunct; but at the same time he most heartily congratulated the citizens on having such a very extensive set of buildings for their new Technical Institute, and upon having taken the lead in this important matter of technical education, upon which this country must largely depend for future successful competition with the other countries of Europe.

A STAGE-PLAY license for the pavilion erected on the pier at Eastbourne has been applied for by the Directors of the Pier Company and refused.

ON Tuesday morning the London and North-Western Railway Company's station at Llandrindod Wells, Radnorshire, was partially destroyed by fire.

ONE of the new kilns of the recently constructed Ogwen Brick and Tile Works, the property of Lord Penrhyn, was fired on Tuesday at Bethesda. Bricks and tiles are to be made from slate rubbish tipped at the famous Penrhyn Quarries, and also from clay dug in the immediate locality. The tiles have been used for the Royal Infirmary, Liverpool, and the Carnarvonshire and Anglesey Infirmary. The development of the new industry has been watched with interest.

ROBERT BOYLE & SON, LIMITED.—The directors of Robert Boyle & Son, Limited, ventilating engineers, London and Glasgow, have resolved, subject to audit, to recommend a dividend of 12 per cent, free of income tax, on the ordinary shares of the company for year ending September last, after placing to reserve fund one-sixth of the profits earned, and carrying forward 1,241*l*. 10*s*. 4*d*.

"HAND ACROSS THE SEA," by Henry Pettitt, will be produced at the Princess's Theatre early in November, and has been strongly cast by Miss Grace Hawthorne. Mr. Henry Neville will play the lead, and will be supported by Messrs. E. W. Garden, W. L. Abingdon, Robert Pateman, Julian Cross, E. Gurney, A. Bucklaw, and H. H. Morrell. Miss Mary Rorke will play the heroine.

"THE STILL ALARM" at the Princess's Theatre will have reached its hundredth night on Friday next, the 26th, and from that date a fire-engine of English manufacture will be used in the famous "Engine-house" scene in place of the American one. Captain Shaw, the chief of the Metropolitan Fire Brigade, has signified his intention of being present on this occasion.

### Surveying and Mathematical Instruments, THEODOLITES, LEVELS, SEXTANTS, COMPASSES, CHAINS, TAPES, DRAWING INSTRUMENTS, ETC., ETC.

Twelve-inch best Boxwood Scales, divided in any manner,  
1*s*. 6*d*. each; by post, 1*s*. 8*d*.  
Twelve-inch best Ivory Scales, 7*s*. 6*d*. each.  
New Builder's Level, ten-inch, with parallel plates,  
mahogany case and tripod, £4 4*s*.

## THE SALTMARKET DWELLINGS, GLASGOW.

IN the minutes of the Improvement Trust Committee submitted for approval at the last meeting of the Glasgow Town Council, Mr. Carrick reported that the cost of the Saltmarket buildings was 9,723*l.* 13*s.* 9*d.*, the interest on which at 3½ per cent. was 316*l.*, which, being deducted from the gross rental, after writing off 25 per cent. for ordinary charges, left a balance of 354*l.* to the credit of the site, a result which was equivalent to 4*l.* 14*s.* 4*d.* per square yard of ground occupied. This rate converted into a ground annual at 5 per cent., and capitalised at 25 years' purchase, raised the ultimate value of the site to 5*l.* 18*s.* per square yard. With regard to the saleable or commercial value of the property to an ordinary investor in heritage, the *cumulo* value might be moderately stated at sixteen years' purchase of the gross rental of 895*l.* The equitable allocation of the proportion applicable to the ground is the balance which remains after deducting the cost of the buildings (9,724*l.*) from the *cumulo* value of ground and buildings together, which, at sixteen years' purchase, is 14,320*l.* The result is 3*l.* 1*s.* 3*d.* per square yard, which, converted into a ground annual and capitalised in the usual way, would show 3*l.* 16*s.* 6*d.* per square yard; giving for buildings 9,724*l.*, and for ground 5,737*l.*, and these together make up the fair commercial value of the subject. With regard to the erection of further buildings on the east side of the Saltmarket, Mr. Carrick reported that the ground northward from the present buildings was sufficient for five tenements of the same size as those already erected. While the cost need not exceed the outlay for the buildings just completed, the rent of the new buildings should be at least 100*l.* more than the 895*l.* obtained for those already erected. The committee authorised plans to be prepared and estimates obtained for the proposed buildings—Councillor Caldwell dissenting.

Mr. Dunlop, in moving the approval of the minute, explained the circumstances in which the Trust had undertaken the erection of these Saltmarket dwellings, and contended that the success which had attended the undertaking warranted them in proceeding with the erection of this block. They had not the slightest desire to proceed further in the matter of building; but by raising the character of the locality they would do something to attract builders to build up the other side. They had no desire to go into any socialistic scheme. As an investment he held these properties had been a success. If anything more was needed to justify them in continuing the extension of these buildings it was that they

had been visited by the most critical and most prejudiced, and they were all satisfied that nothing that had ever been attempted had been so successful as the construction of these single rooms. He believed that if they finished this block they would have a great demand for the houses. The factor told him that there was a demand for even a higher class of houses, while there would be no difficulty in letting the shops.

The minute was approved of.

## AMERICAN NOTES.

IN the October number of *Stone*, a monthly periodical lately started in Indianapolis, the following note appears on the "Beauty of Indiana Stone":—

Professor John Collett directs attention to the stone front of Fletcher's bank building in this city as evidence of the exceptional merits of Indiana's oolitic stone. It has recently been cleaned with steel brushes, and is now brighter than when the building was first erected. The Indiana State-house is built of the same material, and it is destined to become more beautiful as it grows older, Professor Collett says, until it will finally acquire a polish brighter than marble. If the idea that was in view when it was decided to use the Indiana oolitic stone is carried out the exterior of the building will be cleaned with steel brushes every fifteen years, and with each brushing it will become brighter. Why? Professor Collett says that it is because the stone is almost pure carbonate of lime and its impurity is organic matter—petroleum which is oxidised by exposure to air. The stone not only becomes brighter, but it grows harder and more durable with the lapse of time. It should be borne in mind that this is true of Indiana oolitic stone only.

For many years it has been known that California contained marble of a very superior quality, but until recently it has been almost entirely undeveloped, notwithstanding that this State imported large quantities of Italian marble. The Inyo quarries have recently passed into the hands of energetic business men who are developing their resources. The stone has recently been examined by Mr. William W. Wilkins, of Proctor, Vermont, who pronounces it of a very superior quality, of fine colour, nearly white, and of fine texture. There are other marbles in California of different colours which will in time demand attention.

In describing the resources of the Platte Valley, Wyoming,

HINDLE,  
NORTON & C  
OLDHAM

it is stated that there is probably no section enshrouded by eastern fog or shone on by western sun in which nature has deposited more exhaustless or excellent building materials than the Valley of the Platte. It is all here—sandstone of variety of beauty, ease of access, limitless quantity, and quality unsurpassed; granite of formation wide and deep and unchallenged excellence; timber of hundreds of miles in area and growth, mature and magnificent, and beds of building clay of unexplored depth. He that builds can build as he will; he can fashion a mansion in the Platte Valley with the same ease and the nominal expense attending the building of a cabin in other less favoured localities. The sandstone is in great variety as well as limitless quantity. Red sandstone, green sandstone, and sandstone silver-edged are all found, and are all ready of utilisation. The red sandstone, the same stone which in beauty of tint, ease of workmanship, and durability of texture, has made the Rawlins quarries so famous, is probably the greatest in the Platte Valley deposit. This stone is found chiefly in the near vicinity of the Platte River, usually cropping out of the soil of the first and second upland benches. The ledge in which exists the great red stone quarries of the future and the Platte Valley is situated on the same splendid area of bottoms and uplands within whose limits are the famous Saratoga hot springs. The ledge is apparently limitless in deposit, and is most excellent in character. In its soft, red hue it is lovely, yields readily to the chisel, and after being exposed to the air becomes as hard as chilled steel, opposing a front at once polished and imperishable to the attacks of time and the assaults of wind and weather. Within a few steps of the Saratoga Hot Springs Hotel, and sheltering the numerous outhouses of that building as with a rampart of iron, there rises a bold and jutting cliff of this red stone, its massive and weather-beaten front grimly guarding untold quarry riches. Two miles east of the town of Saratoga there begins an immense deposit of sandstone, green in colour. This peculiar hue is given the stone by general, closely diffused copper stains, the natural colour of the stone being a pure, clear white. In geological formation and character this stone is identical with the world famous silver sandstone of Silver Reef, Idaho.

According to an American writer, the palaces of the merchant princes of Chicago surpass those of the ancient Florentine and Venetian Republic. Never before, says the *Chicago Building Budget*, has been seen in the history of the world the log hut changed in fifty years into a city whose

internal decoration can hardly be equalled, even in the older countries, where such masters of their art as Mr. Street, architect of the 12,000,000 dols. Law Courts, Mr. George Aitchison, M.A., A.R.A., and Mr. John P. Seddon, F.R.I.B.A., do not disdain to personally design interior decorations, tiles, stained-glass windows, colour treatment and general artistic as well as constructional details which they have leisure to accomplish, partly through being able to entrust to pupils portions of the work which architects here are compelled to supervise personally, or to employ skilled and, therefore, high-priced assistants.

#### ST. MICHAEL'S CHURCH TOWER, COVENTRY.

A PAPER, prepared by Mr. W. Andrews, of Coventry, and presented last May to the sub-committee for the restoration of the bells, has just been published. He says:—

All the four professional men who have given opinions upon this matter are unanimous that the bells cannot be replaced and rung in the ancient tower with safety to its fabric. These are Mr. J. O. Scott, Mr. Pearson, Lord Grimthorpe, and Mr. J. Thompson, the contractor. The last of the above is very emphatic on this question, and it is obvious that he has had better opportunities of knowing the state of the steeple than the previous three put together. To the above I may add the opinion of the Rev. Canon Cattley, of Worcester, who is a recognised authority upon bells and bell-towers, and who is well acquainted with St. Michael's steeple. To this I may add that the steeple is a yard or so out of perpendicular, a fact which was unknown to some of the above-mentioned professional gentlemen when they gave their opinion. So far as I know, the views of all the amateurs who have given their attention to St. Michael's steeple coincide exactly with the above professional opinions. It may be pointed out that these amateur opinions are not based upon the professional views; on the contrary, they were formed from independent investigations previous to the professional views becoming known. So far as I can discover, one professional opinion only, that of Mr. Pearson, has been given that the bells might be safely replaced and chimed in the ancient steeple. By chiming I mean of course the method of swinging the bells just sufficiently to make the clapper strike, but without raising the bells. Against this I may set the opinion of the Rev. Canon Cattley, who thinks that chiming would cause much vibration and would

### BEAN'S PATENT DIRECT-ACTING VALVELESS WASTE-PREVENTING CISTERNS.

These Waste-Preventers are simple in construction and rapid and powerful in action. The working parts have been improved and are well balanced. The arrangements for charging the siphon are such that a slight pull by hand is all that is necessary to cause the immediate and automatic discharge of the contents of the Cistern.

THE CHIEF ADVANTAGES are—(1) the direct-acting method of charging the siphon, by which the full flush is obtained at once; (2) simplicity of construction; (3) no valve in the bottom of the cistern to cause leakage; (4) no tight-fitting parts to corrode or get out of order; (5) no waste incurred by fastening the "pull"; (6) insures a rapid and regulated flush without holding down the pull.

SOLE MAKERS—

2 NEWGATE STREET, LONDON, E.C.

be risky to the steeple. These views were considered so conclusive that the general restoration committee unanimously adopted on January 13, 1886, and passed a resolution that the restoration of the steeple should be completed strictly according to the contract and specification already entered into. The clearest possible evidence exists that the steeple was never built or intended for either ringing or chiming, but only for bells not to be swung but merely to be struck with hammers or clappers. History mentions that bells were placed in the steeple in the year 1429, viz., before the spire was built, and some writers have given an opinion that the bells were placed in the fourth stage of the tower—that is to say, above the groined vault, and that they were chimed by ropes reaching to the floor of the church a hundred feet below. This, however, is a mistake. Where, then, were the bells placed? An examination of the steeple shows that they were placed in the octagon. The holes in the walls in which the bell-beams were fixed still remain inside the octagon, but no traces of any such holes can be found in the top stage of the tower. This shows that the fourth stage of the tower was for the men who played the bells, whilst the bells themselves were in the octagon above. The bells could not have been swung, or they would have brought the octagon down. Coventry possesses three peals of bells, but at present none of them can be rung, and only one peal can even be chimed. This is from the same cause in all cases, viz., the weakness of the towers. I am old enough to remember the time when the stair turret of the tower of St. John's Church had to be pulled down to prevent it from falling, as it was so badly cracked. It remained down for some years, but has since been rebuilt. The bells here are sounded by ropes tied to the clappers which are banged against the inside of the bells, the bells remaining steady. The peal of Holy Trinity Church is in a similar condition; these bells are also clattered, and the tenor bell has been cracked by this means. It is by no means uncommon for clattered bells to become cracked. My view is that the citizens of Coventry will not be satisfied unless there is one peal of bells in the city which can be rung in full peal, and this should be the best peal, namely, that of St. Michael's. It will therefore be seen that there is only one real solution of this question, namely, to build a new bell-tower and to build it strong enough for its work.

In considering a new bell-tower, the first question to be decided is its site, and whether it should be quite detached from or joined to the church. Some persons imagine that detached towers are very improper and quite unorthodox.

Others think that a new detached tower would in some way or other interfere with the appearance of the old steeples. But the following list which I have compiled of a few of the churches in England and Wales which have detached towers, will show that they are common:—Bedfordshire: Elston, Marston Morteyne, Woburn. Cornwall: Mylor, Gunwalloe. Devon: Chittlehampton. Denbighshire: Henllan. Gloucestershire: Berkeley, Westbury. Glamorganshire: Llangefelach. Herefordshire: Ledbury, Pembridge. Lincolnshire: Fleet, Flixborough. Norfolk: West Walton, East Dereham, Torrington St. Clement, Walton. Northamptonshire: Irthlingborough. Sussex: Chichester. Suffolk: Bramfield, Beccles, Bury St. Edmunds. Warwickshire: Lapworth. Worcestershire: Evesham. There are at least six more in Cornwall, but I do not know their names. I have seen several of these detached towers, and have not noticed anything unsatisfactory in their appearance. The Evesham tower is a very noble one, and stands in the same churchyard with two churches which have steeples. But perhaps the one which may be best compared with Coventry is that of Chichester Cathedral. This cathedral has a steeple nearly 300 feet high, or about the same height as St. Michael's. The bell-tower, 120 feet high, stands in the cathedral yard on the north side. Yet I have not noticed that it interferes in any way with the steeple.

If it should be decided that a new bell-tower should be built entirely and permanently detached from the church, then I am of opinion that it would be best some distance away, and the corner of the churchyard opposite Priory Street seems to be a likely site. I am of opinion that the following dimensions would be suitable for such a tower. Base of tower including buttresses 50 feet square. Side walls about 9 feet thick at base, tapering to 6 feet at top. Height to roof 95 to 105 feet, according to position of tower. Ringing chamber 20 feet square. Clock and chimes chamber of same dimensions. Bell-chamber 21 feet square. Such a tower would weigh between 7,000 or 8,000 tons according to the material with which it was built. Although only one-third of the height of St. Michael's steeple its weight would consequently be much heavier.

#### A MONOPOLY OF PRACTICE.

In the course of a discussion, "Should Architects undertake Engineering, and Engineers Architectural Work?" Mr. F. Harrison, M.V.I.A., of Deniliquin, has written to the

J. HARRINGTON & CO.,  
COVENTRY.

London Address:

398 Fulham Road, S.W.

*Building and Engineering Journal* of Australia and New Zealand. A portion of the letter deals with the question of public buildings. He says:—

For nineteen centuries his name (Vitruvius's) has been a "household word" and his fame without eclipse. He was the light of other days. Now we have the electric light, and, on the shores of a certain lovely harbour, a star that (no matter what its magnitude) puts all other lights in the shade. Permit me to present Mr. James Barnet, F.R.I.B.A., colonial architect of New South Wales; and Vitruvius, my old friend, take a back seat. Your catapults are as shuttle-cocks against the fortifications of Sydney, and you cannot keep up the pace. Rome was right enough till Barnet built New South Wales, but Sydney beats the record. We architects, engineers, and surveyors kept your memory green through nineteen centuries, but each day some teeming brain develops something new, and the total is beyond the capacity of any ordinary cranium. Listen, Vitruvius, and judge for yourself; but though as the centuries roll past on the pages of history another will henceforth eclipse your fame, yet you will not be quite forgotten. Here are a few items of the little bill. Out of the 1,300 public buildings in New South Wales 1,000 are due to the fertile brain of Mr. Barnet. Besides hospitals, asylums, fortifications, and a dozen lighthouses, they include 160 court-houses, 12 gaols, 230 police-stations and lock-ups, 150 post and telegraph offices, designed and built during the leisure the administration of his department affords; time, 26 years; cost, 5½ millions sterling—10,576*l.* 16*s.* annually.

Now, I submit the following suggestion:—Mr. Barnet's prolific brain has been called on to supply a design for some public building once every fortnight for twenty-six years, and though I cannot apply the comment I lately read of a young lady on a flock of sheep, that "they look worthy creatures, but there is a great sameness among them," yet it needs no argument to prove that the little sum represents good work for 100 brains. For the sake of this paltry 10,000*l.* annually (or say 20,000*l.* in the future, for I have not included the State House), would it not be better that the public buildings of the colony should represent fairly the architectural talent of the period, obtained by fair public competition, rather than for a quarter of a century they should represent only the ideas of one individual? Sharing the emoluments is quite a secondary consideration; but, as a question of State policy and public justice, should not the genius of the profession find the means of expression in State buildings, and not be restricted to private enterprise?

In all sincerity and respect I hope that Mr. Barnet will for many long years enjoy the rest he has so well earned. He has faithfully and skilfully performed the duties of a difficult and responsible position for more than a quarter of a century. When old age overtakes us, it is a most grateful and consoling feeling that we have used our talents well; and the colonial architect, when his career is finished, will leave many monuments in New South Wales that will remind future generations of one of her most talented and honourable public servants.

#### GROWTH OF RINGS IN TIMBER.

In a report by the chief of the forestry section of the Agricultural Department of the United States, referring to the annual rings in trees, it is stated that these exist as such in all timber grown in the temperate zone. Their structure is so different in different groups of timber that from their appearance alone the quality of the timber may be judged to some extent. For this purpose the absolute width of the rings, the regularity in width from year to year, and the proportion of spring wood to autumn wood must be taken into account. Spring wood is characterised by less substantial elements, the vessels of thin-walled cells being in greater abundance, while autumn wood is formed of cells with thicker walls which appear darker in colour. In conifers and deciduous trees the annual rings are very distinct, while in trees like the birch, linden, and maple the distinction is not so marked, because the vessels are more evenly distributed. Sometimes the gradual change in appearance of the annual ring from spring to autumn wood, which is due to the difference in its component elements, is interrupted in such a manner that a more or less pronounced layer of autumn wood can apparently be recognised, which again gradually changes to spring or summer wood, and then finishes with the regular autumn wood. This irregularity may occur even more than once in the same ring, and this has led to the notion that the annual rings are not a true indication of age; but the double or counterfeit rings can be distinguished by a practised eye with the aid of a magnifying glass. These irregularities are due to some interruptions of the functions of the tree, caused by defoliation, extreme climatic condition, of sudden changes of temperature. The breadth of the ring depends on the length of the period of vegetation; also when

the soil is deep and rich, and light has much influence on the tree, the rings will be broader. The amount of light and the consequent development of foliage is perhaps the most powerful factor in wood formations, and it is upon the proper use of this that the forester depends for his means of regulating the development and quantity of his crop.

#### MEMEL TIMBER.

MEMEL beams, according to Vice-Consul Pietsch, are required less from year to year in England. Quantities of 75,000 to 100,000 loads, which came down from Russia and Poland fifteen years ago, and found ready customers in England, cannot be disposed of any more to-day; only quantities of about 20,000 to 25,000 loads can still be sold with small profits. Business in oak beams is of no importance any more. For the old stock carried over from former years 65s. to 75s. for crown, 10s. less for the second sort, was paid. The quantity brought down by the Russian dealers was quite insignificant, viz., 5,000 cubic feet, which fetched about 1 mark per foot. In oak wainscots, no transactions took place worth mentioning. The competition of Odessa, from which port wainscots of the same quality as from Memel, with better suitable lengths, are shipped, is not to be overcome. The following prices were obtainable:—4s. for crown, and 2s. 6d. brack, per running foot; for older stocks even these rates were not obtainable, and a considerable quantity remained still in stock. The new supplies consisted only of 1,040 reduced pieces per 18 running feet, against 3,662 in 1886. The demand for oak staves continued pretty brisk during the whole year; 1,304 mille against 1,148 mille in the year preceding were shipped. One mille consists of 1,200 pieces in reduced pipes. Prices showed a declining tendency. In spring 165% per mille crown and 30% less for brack were obtainable; in summer and autumn 155% to 150% for crown had to be accepted. These rates include freight and insurance to England. The new arrivals represented a value of 162,410%, and consisted of 1,250 mille. The larger dimensions, of which only small quantities came down, were much asked for, and for these much higher prices had to be granted by our merchants. Although the shipments to England reached a considerable extent, the profits were but moderate. At the commencement of the year some sales of fir sleepers at 19s.

per load for usuals were effected, but soon this price was not to be obtained any more, and rates receded to 16s. 6d., which low quotation was accepted by Riga dealers. The merchants here, however, refused to sell at such wretched prices. Later on sales at 17s. 6d. to 18s. took place; in the course of the summer prices advanced still more, and 21s. 6d. and even 22s. was paid. The inferior sorts, from 6 to 7 inches surface, were much favoured by the buyers in England, who probably endeavoured to cover their losses caused by the higher prices and freight with inferior quality. Few speculators in England having succeeded in getting the whole sleeper business into their hands, and being enabled thereby to prevent the rising of prices to their former standing, have made it possible that business in this article remains in a quite precarious state. The dealers holding old stocks some years already have experienced heavy losses indeed. The supplies amounted to 157,295 pieces, whereas in 1866 472,972, and in 1885 609,882 pieces of blocks were brought down by the Russian producers.

#### COMPENSATION FOR ANCIENT LIGHTS.

IN the Lord Mayor's Court, the case of *Lee v. Hancock* recently came before the Recorder, Sir T. Chambers, Q.C., and a jury. Miss Lee, daughter and administratrix of John Lee (deceased), sued as the occupier of 38 Warwick Lane, E.C., to recover damages for interference with ancient lights and air, for trespass, and for so negligently rebuilding a party-wall as to cause damage and inconvenience to business, the defendant having premises next door to the plaintiff. Mr. Denniss, counsel for the defendant, argued that, under the Metropolitan Building Act, 1855, a court of common law had no jurisdiction to inquire into the matter of the party-wall. The statute said that that must be settled by arbitration. The only matter which could be decided here was the question of ancient lights and air. The Recorder, after hearing Mr. Candy, Q.C., for the plaintiff, decided that the contention of Mr. Denniss was right, and that he had no power to try the question of damage arising through the party-wall. It was eventually agreed by counsel that, rather than try the case twice, the whole matter should be referred to an arbitrator to be agreed upon. A formal verdict for the plaintiff for 300%, the amount claimed, was then entered. Another action, arising under similar circumstances, was disposed of in the same manner.

## UNIVERSITY EXTENSION CLASSES.

THE University Extension Society at Toynbee Hall has opened its eleventh session in Whitechapel with considerable success. It is noticeable that in spite of the large increase in the supply of higher education at the East End, the demand increases in still greater proportion. The large attendance at the lectures—both literary and scientific—of men and women from all classes, shows that the thoroughness of the teaching provided by the Society meets the needs of an increasing number of students, and the fee of one shilling for ten lectures from thoroughly competent teachers, brings higher education within the reach of many who have been debarred from self-culture by financial limitations, not by want of will. Those wishing to know more of the classes should write to the honorary secretaries, University Extension Classes, &c, at Toynbee Hall, 28 Commercial Street, E.

## POINTING IN FROSTY WEATHER.

IN the Glasgow Sheriff Court recently Sheriff Berry gave judgment sustaining, with expenses, the decision of his Substitute in an action by Messrs. Lamberton & Co., engineers, Coatbridge, against Messrs. H. Symington & Sons, builders in the same place. In a note to his interlocutor Sheriff Berry says:—The defenders contracted on October 12, 1885, to execute the masonwork of a pattern shop for the pursuers, undertaking in their contract to "finish the shop complete for the lump sum of 466*l*., the job to be first-class in every respect and particular." No time was specified for the completion of the work. Whether the clause as to the job being first-class in every respect added anything to be implied, undertaking that it should be executed in a tradesmanlike manner, I do not think it necessary to determine. In any case the work undoubtedly included the tradesmanlike pointing of the brickwork. The pointing was executed as the building proceeded in October and November after the date of the contract, and there having been alternations of wet and frost subsequently the pointing came out. The pursuers, on the defenders repudiating responsibility, had the walls re-pointed; and as they had paid the contract price to the defenders, they now seek to recover the expense of the

re-pointing. I think there can be no doubt on the evidence that it is a risky and imprudent thing to have walls pointed at the beginning of winter. It is said that it is usual, and a practice of trade has been endeavoured to be established, for a workman to point the walls as the work goes on, but I am not satisfied that the evidence adduced is sufficient to establish it as a usage or practice of trade, that in the absence of a special stipulation to the contrary a tradesman who has undertaken to erect a building in a tradesmanlike manner is entitled at the beginning of winter to point the walls, and throw the risk of the pointing holding good on his employer. I agree, therefore, with the view which I understand the Sheriff-Substitute to have taken, that in such circumstances the tradesman who is not limited in time for the erection of a building takes the risk on himself. It is said in the present instance that the pursuers saw the pointing going on, and that they must be held to have acquiesced in it. I think, however, that they were entitled to regard the defenders as doing the job in the manner they thought best for their interests, and taking the risk on themselves. It has been further urged for the defenders that there was delay on the part of the pursuers in having the building roofed; that it was therefore unnecessarily exposed to wet for some weeks, and consequently that they cannot now throw the loss on the defenders. A consideration of the proof, however, does not lead me to think that there is any sufficient evidence of such delay on the part of the pursuers as to exclude them from their claim.

## REGISTRATION OF PLUMBERS.

THE Corporations of the Hartlepoons have been co-operating to promote the system of national registration of plumbers established by the Plumbers' Company. The mayors of both places have just congratulated each other at a public meeting upon the fact that their first co-operation since the incorporation of Hartlepool as a municipal borough should be in a matter of such vital moment to the public health. Dr. Gourley, medical officer of health, who took part in the meeting, said he was sure no one present could fail to recognise the importance of the movement, and he was sure he would have the support of the Health Committee. It could not be denied that in the past no one had given so much work to the doctors as incompetent plumbers. Therefore he hoped the present movement

would go on and prosper, and that before long every plumber, not only in the Hartlepoons, but throughout the country, would be registered.

### MANCHESTER SHIP CANAL.

THE old lower road leading from Thelwall village to Latchford has been closed to the public, the new road, starting from Morris Brook Farm and coming out on the Knutsford Road, being opened for public traffic at the same time.

Coming from the junction of the canal and road towards Thelwall, the canal has now been excavated for its whole width to a depth of one working of the navy, after which for a distance of about three-quarters of a mile work seems at a standstill for the present, with the exception of pumps keeping the cutting free of water. Nearly opposite Thelwall Church a navy has started a heading in the second depth, and for the full depth of some 20 feet it is excavating through a hard solid stratum of red sand, thousands of tons of which are being massed in huge embankments on the north side of the canal cutting. The next active operations are being carried on at "Wilgreaves," an island made by the bend of the river and a lock. At this point the river is to be diverted, to obviate the canal being cut through it twice, and this work, which has been wholly executed by hand labour, is now almost completed, the ends only requiring to be cut through. The huge pile of sand which has been removed from this cutting forms at present a distinct feature of the landscape. Crossing the second bridge leads into Statham. For some time the working in this part was carried on by means of steam "grabbers," but a navy has now taken their place, and has made surprising headway through the sand and clay during the last few weeks. In the early summer another navy started at Statham Lane, heading towards Thelwall, and these two are now facing each other at a distance of about 160 yards, having made a trench or cutting some 20 feet deep and 40 feet wide. In Statham some very fine strong clay has been cut to, and this is being utilised by the contractor for brick-making purposes. A very complete and elaborate plant has been laid down, with a pug mill in full work and another being erected, and these two, when in full operation, will turn out about 200,000 bricks weekly. This quantity can be continued all the winter through, as large sheds capable of drying by means of flues 160,000 bricks each five days are now in full working order. Five large Scotch kilns (another is being erected), capable of burning 100,000 bricks in

four days, are also in operation. This locality, where twelve months ago was unbroken meadow land, is now teeming with busy life. A number of wooden cottages have been built and tenanted, valuable engines and machinery are in motion, lines of railway and locomotives in all directions cover the ground where a few years ago a freshet from the river inundated the land to a depth of 4 or 6 feet. Passing over the next bridge, an island, known as Rixton Ley, is entered, and this would seem to be composed of quicksand. On this section a German navy somewhat on the principle of a dredger is at work. Two locomotives are engaged in attending on this expeditious worker, which can fill 500 waggons a day. Passing over the next bridge, Lymm Eye is reached, and from this to Warburton, a distance of about a mile, only hand labour, assisted by locomotives, is engaged.

Although during one week the navvies on the Barton and Eccles and Irlam and Flixton sections of the Ship Canal works were compelled to cease work at intervals in consequence of the boisterous and inclement weather, a visit to examine the works revealed considerable progress in their construction. At Sticken's Island not only has the required depth of the canal been reached, but the foundation of one of the large locks has nearly been completed. The formation of the track railway underneath the southern arches of the aqueduct and Barton Bridge is in a forward condition, and ledges have been cut into the solid rock on the southern bank of the river. A portion of the hedge separating the river from a field adjoining the highway opposite St. Catherine's Schools has been taken down, and the necessary preliminaries are being pushed forward for the construction of the railway through the field until it reaches the river about 100 yards lower down, and piles are there driven into the bed of the Irwell for the continuation of the railway across on to the Salt Eye meadows. At Boat Lane, Flixton, quite a colony is being established, there being already erected over twenty workmen's huts, in addition to a hospital, the contractor's offices, stores, and engine sheds. Excavations have been commenced in the meadows at Lower Irlam, and the ballast railway from a point south of Irlam station, on the Cheshire lines, has been extended to beyond the Calemanka locks in the direction of Hulme's Bridge, and after two or three wooden bridges have been erected across the river, the Irwell at this point taking a very zigzag course, there will be one continuous length of lines from Salford to Irlam. Three additional locomotives were employed last week on the Irlam and Cadishead section, which now ranks amongst

### SOMETHING NEW AND EFFECTIVE.

### DRUMMOND'S NEW PATENT PRISMATIC ROLLED GLASS

Marks an entirely new era in Glass Roofing, increasing Daylight and excluding Leakage.

For Glazing Windows, Roofs, Partitions, Doors, Stallboards, Pavement Lights, Ship Skylights, Deck Lights, Lamps, &c.

Made in Large Sheets for Cutting to Sizes as the ordinary Rough Glass. Also in Tinted Cathedral, for Church Windows and Screens, giving a rich and dazzling effect that is not attained by any other Glass in the Market.

SAMPLES AND PRICES ON APPLICATION TO

DRUMMOND & LINDSAY (SOLE MANUFACTURERS), 35 Montrose Street, GLASGOW.

### "PERFECTUM."

In London the above are kept in stock by Messrs. GEORGE WRIGHT & Co., 155 Queen Victoria Street, E.C., who will be pleased to show and explain them to Architects and Contractors.

On view at the Cardiff Exhibition, September and October, and at the Ironmonger's and Metal Trades Exhibition, London, November 14 to 24, 1888.

TELEGRAMS—"PERFECTUM," BOLTON.

The "Perfectum" will be exhibited in the Parkes Museum, London, and at the Glasgow Exhibition.

Architects can have a Model Free of Cost on application.

See Illustrated Advertisement first week in each month.

the most active on the whole undertaking. Between New Barns, Salford, and the Boathouse, Hollins Green, twelve track bridges have been made across the river for ballast lines.

### THE ENGINEER OF THE FUTURE.

*Concluded from last week.*

Now, in the matter of the training of engineers, the alternatives which are being discussed at the present time in this country are, an apprenticeship beginning at an early age, after only a very ordinary school education, or a course of practice in the works, preceded or followed by a course of training in one of the colleges in which the scientific principles which underlie practice are taught. Now, to my mind it is self-evident that the scientific basis of practice should be known and understood by all who have to direct that practice. Underlying all the rapid developments of practical engineering there are the unvarying laws of nature, which all the works of our hands must obey, however ignorant we may be of them, and however we may plan and fight against them; "and," as Professor Huxley puts it, "nature never overlooks mistakes or makes the slightest allowance for ignorance." Every item of good practice must have its reason and its explanation in the nature of things, whether we know that reason or not. To every effect there must be a cause, to every how a why, and every cause and every why is knowable. We are still far from knowing all; but let every one who has to act upon the how know all that he can of the why. We often—I might almost say usually—hear theory spoken of as something almost necessarily at variance with practice. No notion could be more absurd or utterly ridiculous. Theory—properly understood—is an orderly system of reasoning regarding the causes of things. Can the causes of things be at variance with their own effects? Every business man knows how invaluable is system and order to him in all his transactions, and he is not content to know simply that he has so much to the good, or to the bad, at the end of a year; but he must know the details of every transaction, where he has gained and where he has lost, so that he may profit by his experience. And so it must be in engineering practice. To have a firm grasp of his work, the engineer must know not only, for instance, that an engine gives such and such results, but why it gives them. Where does the economy

come in, and where are there sources of loss that may be avoided in the future. All this is self-evident, I say, to my mind; but there are those who will tell you that it is not so. They tell you that you are to conduct those dealings of yours with the "sources of power in nature," without putting your transactions in any orderly form. It is enough for you to grope your way by hard lessons of failure and chance runs of luck, without making up, even in your own minds, a profit and loss account, and tracing out to what causes your successes have been due, or where you have missed the way and failed. I quote the *Engineer*:—"At the root of all this worry about technical education lies the delusion that unless men are taught certain things they cannot produce, let us say, steam-engines, or cotton, cloth, or iron, the fact being that a knowledge of the things in question is wholly unnecessary." There is something of melancholy truth in this. We know that men can and do produce steam-engines with no knowledge of theory, just as men conduct business—on a very large scale too—without keeping accounts, and some one has to bear the consequences. Is it to the credit of engineering to-day that, though Watt a hundred and twenty years ago introduced the principle of steam jacketing, we should find an engine submitted for a competition in this 1888 with a wet blanket of exhaust steam around the cylinder; and that, too, in the case of an engine with a very high range of expansion in one cylinder? This "seems scarcely credible, but it is true." Or are we to look with satisfaction upon the practice of to-day, when we find engines now being made which can do no better performance as regards economy of fuel and water than those which Watt's genius and knowledge produced so long ago? And our engineers of to-day, in many—I may say most—cases are quite ignorant of any accurate methods of determining even what their engines can do. But many engineers hold, with Lord Armstrong, the view that all the information which those require who are to direct labour "can be found in a condensed and tabulated form in handbooks applicable to all kinds of constructive art. Such technical information is in this form available to every man who can read and do arithmetic, however ignorant he may be of the scientific methods by which such tabulated results have been arrived at." I am sorry to have to differ from so high an authority; but I can assert, without the slightest hesitation, that to all scientific men who have come much in contact with those who adopt this method, it is notoriously not the case that they can correctly read and apply such information.

PATTERN BOOKS ON APPLICATION.

To comprehend, however, the very special need which exists for scientific knowledge on the part of our engineers at the present time, we must look at the position we have reached in the development of our craft. When a great new departure is to be made in any craft, the first question must be as to what to do, and when that is settled the difficulty must be faced of how to do it. The first step, then, is in theory; the next is in practice, or in handicraft. The early engineers laid a foundation of principles upon which to act, and lines along which to proceed, and the succeeding generations had to find out how to carry these ideas into effect. In this part of the work, in mechanical engineering at least, the great labour has been in the invention and perfecting of the tools, and in training men's hands to the new employments. And so we find, in the history of the steam-engine, for instance, that the work of the successors of Watt and Stephenson has mainly been the carrying out to successful practice of the ideas which they and their contemporaries and immediate successors gave us as a legacy. Few great and radical improvements in principle have been introduced in engine-building since their times. But now we know that we can make almost anything that can be designed, and that with an accuracy and perfection—thanks to our system of division of labour—which is truly wonderful. Again we have reached a stage at which the question is not how to manipulate our materials, but into what our materials shall be fashioned. Hence the necessity for a new race of scientifically trained engineers, and from this need have arisen such places of education as that in which we are met.

Our thinkers and investigators have given us a wealth of pure scientific knowledge, and we have a legion of highly trained privates in our mechanics, equipped with implements of wonderful precision, ready and waiting to execute the commands of their generals and captains, the engineers. Our work then, as engineers, is to put into and adapt to our immediate needs and put into operation the methods of attack which the investigators, with a full knowledge of the possibilities which lie before us, have supplied for our guidance. The engineer must be the interpreter of scientific truths, and to this end he must know those truths; and hence it is the work of colleges such as ours to teach those scientific principles and their application to practical problems. The former is the work of the departments of mathematics, of physics, and of chemistry, and the object of the engineering department is to teach and to train its students in the methods and processes by which the principles of those sciences may be transcribed into the practice of engineering.

The aim of the whole, so far as engineering is concerned, is to supply to the student the rules and laws which must guide him in his work, and the mental ability to correctly perceive and to apply them.

I have said, then, that our present position is akin in many respects to that in which the early engineers found themselves, though vastly wider and more full of promise. Now the statement is constantly being made that the great leaders in engineering have been simply practical men in the modern sense of that term—that they have undergone such an apprenticeship from an early age as certain so-called authorities would have the engineers of the future to undergo. Nothing could be more misleading. In some few cases these leaders have had only a practical training, in some only a theoretical one; but in most they have—as we advocate—undergone a course of practice and a course of study. I shall endeavour to give you as briefly as I can the life histories of the great leaders in engineering, so far as this question is concerned. I think I do not make an unfair selection when I take Smeaton, Telford, John Rennie, George Rennie, Watt, Fairbairn, George Stephenson, and Robert Stephenson as representing the engineers of the early period. And I should wish you specially to notice in how far the careers of those men bear out the principle of an early apprenticeship, and how far they support the contention that a knowledge of scientific principles is necessary for the engineer.

### PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

### APPLICATIONS FOR PATENTS.

14665. William Whalley Cottam, for "The Utilisation of earthenware and other pipes, by the aid of a flap or valve, for closet-flushing purposes." October 12, 1888.

14681. Joseph Tolterton, for "Improvements in fireproof curtains for the stages of theatres and the like." October 12, 1888.

## GRUNDY'S PATENT WARM-AIR VENTILATING FIRE-GRATE.

The novelty, superiority, and advantage of this patent consist in the heating surface being greater than any other Fire-grate introduced to the public. It is very simple in construction, and is made in the form of a Stove, the back of which is semicircular in shape, with gills behind and smoke-nozzle on top, all cast in one piece. The same can be attached to any design of a Register or Stove front. It is very suitable for schools, class-rooms, waiting-rooms, hospitals, offices, dormitories, and dwelling-houses, from the cottage to the mansion. Design and specification post free on application.

### TESTIMONIALS.

9 Victoria Chambers, Westminster, S.W.  
SIR,—I have much pleasure in testifying to the efficiency of your patent warm-air fire-grate. It has been very successful, and given every satisfaction where I have used it.  
Yours, &c., JAMES WEIR, F.R.I.B.A.,  
To Mr. Grundy. 6 John Street, Bedford Row, W.C.

From Hon. and Rev. G. G. C. TALBOT, M.A., Withington, Cheltenham.

DEAR SIR,—You will be gratified to hear that the school is completely warmed by your new grate. It is the most economical and efficient that I have ever seen.  
Mr. John Grundy.

### ACROSTIC.

Just listen, friends, to what folk say  
Of Grundy's patent warm-air grate,  
How with the fresh air channels they  
Not only warm, but ventilate.

Give wondrous heat, burn little coke,  
Require but slight attention paid,  
Unequalled for consuming smoke,  
No better grates were ever made.  
Do try just one of Grundy's glo,  
You then will all its merits know.

### APPLY TO

CORSHAM, WILTS.

Note.—No Connection with the other BATH STONE FIRMS.

14685. William Henry Kent, for "Improved combined pocket-eraser and case." October 12, 1888.

14687. John Lowe, Harry Marvin Abbott, and George Gwilt, for "An improved portable electric lamp, applicable also for house lighting." October 12, 1888.

14707. Joseph Hibberson, for "Improvements in valves, taps, or stop-cocks, for gas, water, or other fluids." October 13, 1888.

14709. William Horsfall, for "A new or improved construction of furnaces, for burning town's or other refuse." (Complete specification.) October 13, 1888.

14724. Lawrence Wilson, for "Improvements in parquetry, and other similar composite wood, and artificial wood surfaces." October 13, 1888.

14733. Alexander Noble, for "Stonemason's points or chisels, double pointer, and chisel-holder." October 13, 1888.

14734. Bridgman Russell, for an "Improved air-inlet ventilator." October 13, 1888.

14743. John Morphew Martin, for "Draught and dust-preventer to supersede the old-fashioned sand-bags." October 13, 1888.

14746. John William Youngson, for "Self-fastening, burglar-proof sash-fastener." October 13, 1888.

14750. Clement Wain and Augustus Clery, for "An improved cement or artificial stone." (Complete specification.) October 13, 1888.

14759. Alexander Robert Murison, for "Single and double-acting pumps for all liquids." (John Christie, ss. *Attonower* at sea.) October 13, 1888.

14768. Alfred Coxon, for "Improvements for drying slurry in the manufacture of cement, by the use of an extracting fan, to create a draught for kilns, furnaces and boilers." October 13, 1888.

14786. James Broadhurst, for "An improved oven or kiln for firing pottery and other articles." October 15, 1888.

14790. Benjamin Amulson Dougherty, for "The detection of heat and fire on board ship and on shore, in houses and warehouses." October 15, 1888.

14830. William Marston Derrick, for "A new or improved method for the ornamentation of glass." October 16, 1888.

14853. George Pankhurst, for "An improved brick, tile or slab for building and other purposes." October 16, 1888.

14870. Theodor Kromer, for "Improvements in keys for doors and other locks." October 16, 1888.

14881. Thomas Houlding Bromly, for "A combined circular

saw, gig saw, lathe, drilling, milling and mortising machine, moulding, punching and key way cutting machine, &c." (Complete specification.) October 16, 1888.

14900. Thomas Robinson Paxton, for "Improvements in attaching door knobs to their spindles." October 17, 1888.

14968. Walter Stead, for "An improved method of constructing and suspending the vertical sliding sashes of windows, &c." (Complete specification.) October 18, 1888.

14970. Frank Prail, for "A portable combination ingle-nook or enclosed chimney corner." October 18, 1888.

#### PROVISIONAL SPECIFICATIONS ACCEPTED.

11814. Benjamin Barstow Snell, for "A spring catch to be applied to fasteners of doors, sashes and shutters, which locks cross-bar and entirely prevents opening from outside." August 16, 1888.

12111. Thomas Gahan, for "Improvements in ventilating screens for windows and similar openings." August 22, 1888.

12533. John Balbirnie, for "Improvements in fireplaces, grates, ranges, stoves and furnaces." August 31, 1888.

12685. Alfred Henry Spaul and Cornelius Callan, for "Improvements in window-sash fastenings." September 3, 1888.

12799. Hiram Jefferson Wells, for "Improvements in pumps." September 4, 1888.

12884. William Hickens Rickard and Thomas John Rickard, for "Improvements in or connected with hydraulic safety apparatus, applicable to hydraulic lifts or cranes, steel converters, and such like machinery." September 6, 1888.

12924. John Bradshaw, for "A chimney pot or top." September 7, 1888.

12984. George Robinson Cumpston, for "Improvements in means for preventing the spread of fire in buildings." September 8, 1888.

13199. James Hopwood, for "Improvements in the valves of taps for steam, water, or other liquids." September 12, 1888.

13225. George Chatterton Soper, for "Improvements in or relating to apparatus for mitring frame and panel mouldings and the like." September 12, 1888.

13305. Alfred Julius Boulton, for "Improvements in wood-planing machines." (Pedro Dominquez, Spain.) September 14, 1888.

13327. Hiram Waddington, for "Improvements in draught-preventers for doors or windows." September 15, 1888.

13384. Thomas Penn and Alfred Edward Penn, for "Improvements in and connected with oil-lamp and other burners

# KALLKOLITH.

## NEW PATENT PRIMING AND STAIN.

Acknowledged by experts of nearly every country to be one of the most important inventions of the Nineteenth Century.

PATENTED IN  
England,  
Belgium,  
France,  
Germany,  
Italy.

PATENTED IN  
Austria-  
Hungary,  
Denmark,  
United  
States  
of America.

TRADE MARK.

**KALLKOLITH** is one of the most marvellous inventions of the present age, and is used as a priming in place of the now almost obsolete oil-colour. It produces an exquisite smoothness, combined with great durability, and amalgamates thoroughly with wood, iron, cement, stone, plastering, &c.

**CHEAPNESS.**—It saves at least 100 per cent. in comparison with any other priming now in use, being less than half the weight.

**ECONOMY** is manifested by the fact that one 14-lb. tin of **KALLKOLITH** goes further than three times the same quantity of oil-colour.

**DRYING POWERS.**—It dries within one to two hours, thereby greatly facilitating the quick dispatch of labour.

**DURABILITY.**—Where **KALLKOLITH** is used it imparts an amount of durability to all oil-colours used upon it which has never yet been obtained, and one of the most important advantages in its use is that the paint put upon it does not blister.

**PAPER-HANGING.**—Walls prepared with **KALLKOLITH**, thinned with seven parts of water, give a great additional advantage to the hanging of all descriptions of papers.

#### TESTIMONIALS.

21 New Bridge Street, London, E.C.: February 23, 1886.  
I have had some trials made with the **KALLKOLITH** during the past few weeks, the results of which are very satisfactory. The **KALLKOLITH** is to be used as the first coat of paint on wood and other substances, and is of such a nature that the ordinary work in preparing for paint is considerably lessened, and the usual number of coats now given receded, and, once fairly introduced in the market, I am certain there will be a large sale.  
J. W. M. STEVENS, Architect and Surveyor.

75 Newman Street, Oxford Street, W.: Feb. 15, 1887.  
We are pleased to tell you that the **KALLKOLITH** supplied to us has been fairly tried, and we find that it answers all that you claim for it.  
CAMPBELL, SMITH & CO.

Price per case of 8 Tins of 14 lbs. each, net 40s., packing included. Special terms to Wholesale Buyers and Shippers.

Address—**KALLKOLITH CO., 175 STRAND, LONDON, W.C.**

or jets used for the burning of any hydrocarbon, and in the means or apparatus for operating the lighting and extinguishing of the same." September 17, 1888.

13525. Walter Ralston, for "Improvements in wall-papers." September 19, 1888.

13574. William Job Howcroft, for "Improvements in vehicles employed in the removal of mud and other refuse." September 20, 1888.

#### COMPLETE SPECIFICATIONS ACCEPTED.

Notice is hereby given, that all persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the date of the official *Journal*, give notice at the Patent Office in the prescribed form of such opposition.

14384. Richard Hocking and William John Hocking, for "Improvements in and relating to water-closets." October 22, 1887.

16048. Thomas Wilkins, for "Improvements in raising or adjusting mechanism for window-sashes and other sliding articles of similar character, required to be raised and lowered." November 22, 1887.

16510. Benjamin Oldfield and William Oldfield, for "A method of ornamenting in imitation of marbles and grained inlaid woods in combination with printed designs." December 1, 1887.

17206. Alfred James Hopkins, for "Improvements in water-closet apparatus." December 14, 1887.

17993. Joseph Winterflood, for "Improvements in chimney and ventilating cowls." December 31, 1887.

9556. James Holroyd, for "Improvements in the construction of faience or glazed terra-cotta mantelpieces, firesides, fronts of grates, and fenders for hearths or firesides, and such like articles." June 30, 1888.

13354. Johannes Sjöström, for "Improvements in, or relating to, fences or barriers, and supporting posts therefor." September 15, 1888.

13430. Clarke Merchant, for "Improvements in cowls for ventilators and chimneys." September 17, 1888.

#### PATENTS SEALED, OCTOBER 19, 1888.

10808. John Hurst, for "Improved apparatus or pump for lifting water—muddy or otherwise—or any other fluid or water mixed with sand or other gritty material." August 6, 1887.

11237. Harry Noble and George Haley, for "Improvements in the hearths of fireplaces, fenders, and dados of metal and enamel." August 17, 1887.

13407. Henry Marle, for "An improvement in drawing apparatus, viz., a demonstration stand for solid drawing models." October 4, 1887.

13534. Thomas Charles Hutchinson, for "Improvements relating to the treatment of blast-furnace slag, for the manufacture therefrom of hydraulic or similar cement." October 6, 1887.

13537. Thomas Constantine Fawcett, for "Improvements in brick-making and brick-drying machinery." October 6, 1887.

13976. William Henry Moore, for "Improvements in apparatus to prevent the bursting of water-pipes by frost." October 14, 1887.

4518. John Henry Marston, for "Apparatus for opening and closing fanlights, skylights, or casements." March 24, 1888.

9733. Elliott Emanuel, for "A double fan for wash-out closets." July 4, 1888.

#### ABRIDGMENTS.

"Improvements in the manufacture of material for use in the construction of fireproof curtains of theatres, ceilings, columns, partitions, &c." No. 37082. 1888. John B. Lee, of the Titancrete Co., 8 Deansgate, Manchester.

*Claim 1.*—The manufacture of the specified and indicated articles from a material or composition consisting of a mixture of cement or concrete and asbestos fibre, either with or without a further addition of finely broken or crushed slag, coke, fire-brick, or other suitable non-combustible material, in the manner for the purposes and substantially as hereinbefore described and shown.

"Improvements in the manufacture of decorative leather." No. 12393. 1888. H. J. Haddon, 18 Buckingham Street, Strand.

*Claim.*—The moulding of leather by pressure in a suitable mould by rubber sheets or the like, substantially in the manner described.

TO INVENTORS. — Patents for Inventions, Trade-marks, and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & CASSELL, Patent Agents, 43 Southampton Buildings, Chancery Lane.

## Wilson's Patent Dioptrical Pavement Lights.

WILSON & CO. beg to call the attention of Architects and others to the superiority of Wilson's Patent Dioptrical Lenses for pavement and floor lights. These Lenses are constructed on strictly scientific principles, and have been approved by some of the highest authorities on Light. They are made of the Best English White Flint Glass of high refractive power, and transmit more light than any other form of Lens yet introduced. The reflecting surface being spherical, the rays of light are distributed in every direction.

Wilson's  
Patent Lenses  
for  
Floor Lights,  
Deck Lights,  
and  
Pavement  
Lights  
of every  
description.  
Sample Lenses  
on  
application.

Wilson's  
Patent Lenses  
for  
Stall Boards,  
Cellar Flaps,  
Ornamental  
Tile & Glass  
Pavements,  
Safety Coal-  
Plates.  
Plans, Prices  
and Estimates  
Free.

Fig. 1 shows how the ordinary prism or semi-prism, by receiving the rays on a plane reflecting surface, throws them forward at one angle only, in parallel lines close to the ceiling.

Fig. 2 represents the Patent Dioptrical Lens, and shows by comparison how the rays of light, striking on the curved inner surface, are reflected forward through the face of the lens in every direction, filling the whole angle of 90°, thus illuminating the apartment from floor to ceiling and from wall to wall.

From the above diagram it will be seen wherein consists the advantages claimed for Wilson's Patent Lenses. The objection to the semi-prism is that it reflects the light, as shown in Fig. 1, at such an angle as to be of little use, and more especially if the line of the ceiling in below the line of the pavement; then the value of the semi-prism as a light projector is entirely lost.

It will be seen also, on reference to the above diagrams, in Fig. 1 that the first row of semi-prisms obstructs the rays of light from each succeeding row, whereas in Fig. 2 the bulk of the rays of light are projected at such angles as to pass unobstructed into the room.

The correctness of these illustrations can be practically demonstrated to any architect desirous of testing them.

PRICE LISTS AND ESTIMATES ON APPLICATION TO

# THE "THOMAS" LAMP.

Lighting Power with  
ordinary London Sixteen-  
Candle Gas, from tests  
taken by Professor Wm.  
Foster, M.A., L.R.C.S.

No.	
10.	11.4 Candle-power per foot.
11.	12.5           "           "
12.	12.5           "           "

These Lamps are made in three  
sizes, Nos. 10, 11, 12.

These Lamps can be obtained through Gasfitters, Ironmongers and  
Merchants. Foreign Orders through Merchants only.

The advantages of this Patent  
over other existing Lamps  
are:—

Small consumption of Gas  
with great Illuminating power.

No possibility of the Burner  
corroding or getting out of  
order, as is the case with other  
generative gas lamps.

The Lamp can be fitted by  
any gasfitter. No fine per-  
forated metal, gauze, or other  
obstructions are used in this  
Patent, as in other lamps which  
are liable to become choked  
through imperfect combustion,  
rendering the lamps smoky and  
useless.

FOR FURTHER PARTICULARS, APPLY TO

**Ridsdale's Railway Lamp & Lighting Company, Ltd.,**  
**55 & 56 MINORIES, LONDON, E.C.**

# The Architect.

## THE WEEK.

THE Royal Scottish Academy has long remained in a condition that needs reform. As a means towards that end the governing body have received petitions for an increase in the number of the Associates, and for the conferring voting powers on the Associates. They come from artists who do not belong to the Academy and from the Associates. It is generally supposed that the Academicians of Edinburgh have a higher opinion of themselves than their brethren in London, and a manner of superiority is sometimes adopted by them which is amusing. No wonder so many young artists, when they dream of the possibility of one day having to assume such airs, should fly southwards in order to escape from the ridiculous. At the present time any reputation which the Academy may possess is derived mainly from the works of the Associates. Let any amateur be asked to recall pictures or statues by one-half of the Academicians—and we may throw in the President—he will find himself in a difficulty. Their works have already passed out of recollection. Is it wise to have so many nonentities ruling the Academy, whilst the ablest members are in the position of the outside public?

THE new Spalding Club bids fair to rival its great predecessor. The full measure of five hundred members is maintained, and it is as difficult to gain admission into the society as to become a member of a select club. The two works issued during the year were "Memorials of the Family of Skene of Skene," with reproductions of sketches by the late JAMES SKENE of Rubislaw, and "Cartularium Ecclesie S. Nicholai Aberdonensis," with copies of sketches by Mr. G. REID, R.S.A. The illustrations have delayed the production of the books, but before the end of the year it is anticipated the monograph on the heraldic ceiling of the cathedral church of St. Machar will be ready for presentation to the members. The Lyon king of arms will explain the heraldry. Among the works which are in progress are the following:—"Collections for a History of the Shires of Angus and Mearns"; "The Folklore and Place Names of the North-Eastern Province"; "A History of the Family of Burnett"; "The Register of the Scots College at Rome"; "The Diary of the Scots College at Douai"; "A Bibliography of the Shires of Aberdeen, Banff, and Kincardine"; "A Calendar of the Correspondence in the Town-house of Aberdeen"; HECTOR BOECE'S "Lives of the Bishops of Aberdeen," reprinted from the edition of 1522; "Selections from the MS. Biographical Collections of the Rev. ROBERT WODROW, in the possession of the University of Glasgow"; "The Chartulary of the Church of St. Nicholas"; "Selections from the Records of Marischal College and University." The Archæological Committee have also issued a circular relative to the folklore, place names, and bibliographical investigations.

THE Glasgow International Exhibition is now drawing to a close, and the fate of the buildings has had to be determined. When the ground was conceded to the Executive Committee for the erection of buildings, it was agreed that the site was to be restored to its original condition. The committee considered it would be better for all parties to make over the buildings to the Town Council, on the understanding that the restoration of the site would devolve upon the Council. At the same time it was suggested that it would be well if the Council preserved that part of the buildings which formed the Fine Art Section until a fine arts gallery worthy of Glasgow was provided. Another suggestion was that such models and exhibits in the Indian Section as were considered fit for exhibition in the Museum of Glasgow should also be taken. Valuable gifts are thus made over to Glasgow in the simplest way. It would be well if the whole of the exhibition buildings could be conserved; but they are mainly constructed of wood, and it has yet to be seen whether they can stand a Scotch

winter. In June a good deal of damage was done by the rain which found admission to the stalls. But if the buildings could be rendered watertight, they could be well utilised for an industrial museum without any detriment to the art galleries. The Town Council will have time to consider the question, for it is well to know that on Tuesday the offer of the Exhibition Committee was accepted.

THE definition of what is an inflammable or combustible roof was tested on Tuesday in the Westminster Police Court. The district surveyor for St. Margaret and St. John, Westminster, summoned the secretary of the Royal Aquarium for infringing the Building Act by covering the Aquarium with a material that was combustible. It was described as a close wire mesh embedded in a gelatinous substance, and is supposed to be a foreign production. Witnesses stated that the new roof was practically fireproof. Mr. WILLIAM EMDEN said he considered that a glass roof was a constant source of danger. In places of amusement where it existed he had had wire netting put above, and in some instances under, the glass, because contraction and expansion caused breakage, and, in the event of fire, burning embers fell through glass without hindrance. Molten glass would pierce any one like a bullet. The magistrate gave judgment against the surveyor. He said there was hardly a substance that could be described as incombustible. It was a question of degree, and as he considered that the roofing complained of came within the definition of un inflammable, "not easily lighted," he felt that he should be doing a grievous injustice if he strained the Act of Parliament to decide that the Aquarium skylight was combustible, and order it to be removed at an enormous expense. The summons was therefore dismissed.

THE programme of the Leeds and Yorkshire Society for the coming session, which opens on the 12th, cannot be objected to on account of wanting interest. On November 26, Mr. A. MARSHALL, of Nottingham, who has published books on the subject, will discourse on the "Furniture and Woodwork of the Seventeenth Century." Mr. J. A. HEATON will next follow with a paper on "Beauty in Colour and Form; How to Seek, Where to Find," which ought to ensure a large audience. At the first meeting of next year, Mr. J. S. GARDNER will explain "Art Metalwork." Mr. R. T. BLOMFIELD takes up "Architects of the English Renaissance" for a theme, and Mr. R. J. JOHNSON will put in "A Plea for Old English Art." Miss GARRETT, who has made a mark as an artist for the household, will talk about "Interior Decoration and Furniture." Decoration inspires another author, for Mr. SCOTT MORTON is to expound the mysteries of "Colour in Architecture and Interior Decorations." Lastly, Mr. HADFIELD, of Sheffield, will bring the series to a close with a paper on "Canterbury Cathedral." It would be well if all the metropolitan societies had command of so excellent a set of contributions.

MR. JOHN GRIFFITH, who has died at the great age of ninety, was for many years well known among the architects of the City, where he resided as well as practised. Although most benevolent and generous, he has left over 170,000*l.* and about 20,000*l.* will be distributed for charitable purposes. His fortune is much larger than the one left by Mr. JAMES EASTON, who was prominent as an hydraulic engineer. The firms of EASTON & AMOS and EASTON & ANDERSON carried out several large contracts for waterworks, and their hydraulic machinery was known all over the globe. Mr. EASTON was considered to be a very rich man, but recent losses probably were the cause of his executors not having to pay duty on a larger sum than 91,000*l.*

SCULPTORS who care to enter into a competition have now a chance. It is intended to erect a bronze statue in Grantham of the Hon. F. J. TOLLEMACHE, who at one time represented the borough, and the sculptor is to be chosen by competition. The height of the statue will be from 7 feet to 9 feet. The money for the work appears to be easily obtained, for already subscriptions are promised amounting to over 1,500*l.*

## SIR WILLIAM SIEMENS.\*

A PHYSIOGNOMIST, who closely observed Sir WILLIAM SIEMENS on the evening when he conducted the Princess of WALES through the Fisheries Exhibition at South Kensington, must have concluded that the chairman was either very weary or very ill. He went through the task mechanically, without any apparent recognition of the privilege of his position, which was the crowning point of his career, and at times his voice sounded as if he were speaking a language which he was unable to comprehend. Yet in physique Sir WILLIAM appeared a strong and large-boned man, he stood nearly six feet in height; he was broad-chested, and well set up. The face, although at the time lacking in expression, was not without power, the forehead was ample and well developed, the bushy whiskers were parted to reveal a firm chin, and as his locks were scanty, there could be no objection raised against that redness which at one time brought him a nickname. The mouth was unusually large, and suggestive of a man who had little mercy in offering sacrifices to gain his own end. Did the excitement of that night tell more upon Sir WILLIAM than he was able to realise? A few months afterwards he knocked his foot against the kerbstone in Piccadilly and fell. In a fortnight he was dead, and then the doctors announced that under any circumstances he could not have lived long, and, as usual in such cases, they wondered how he reached his sixtieth year.

Two-thirds of his life were spent in England. During that time his name repeatedly appeared in the lists of patents, and he figured as an engineer, a manufacturer, and a man of science as well as an inventor, but he was only beginning to gain some popularity when he was so suddenly carried off. It was, in fact, difficult to imagine him as an individuality. He was one of four brothers who were all men of importance, three of them resembling Sir WILLIAM in inventive power, and as their business was world-wide, it was not unreasonable to suppose that SIEMENS was simply the distinguishing mark of a great company comprising many personalities and a variety of names.

That mighty business was the creation of poor men, who had to depend for success upon their own exertions. They were not only the heads of the firm but continued to be its chief workmen, upholders no less than creators. What is still more remarkable is that they were successful because they were scientists. They first worked out their schemes in theory believing, like all Germans, in the poet's words:—

Mit dem Genius steht die Natur im ewigen Bunde;  
Was der eine verspricht, leistet die andre gewiss.

For that reason the history of the SIEMENS family has an especial importance at the present time, when so much is talked about the subject of technical education. Few men can be so fortunate as the brothers in being among the earliest to utilise powers of nature which were supposed uncontrollable, but all may at least learn to imitate them in depending on principles rather than on empiricism, and in recognising the superiority of reasoning over accident.

The father of so notable a family was a farmer, who was well educated according to the old system, but he could not be more ignorant of science if he had been brought up in an English university. He died in his fiftieth year, when his eldest and cleverest son, WERNER, was twenty-three. Sir WILLIAM SIEMENS was the fourth son, FRIEDRICH was fifth, and CARL the sixth son. Two other brothers also made their mark, but in different ways.

WERNER, having entered the Prussian Artillery, rose to be superintendent of the workshops. He was a type of the scientific officer. He can claim to be the inspirer of his brothers, and under his direction they made their fortunes. When he was a cadet at Magdeburg in 1838 he proposed that WILLIAM, then a boy of fifteen, should enter the trade school of that town and be under his care. As the number of subjects in the school was limited, WERNER undertook to teach his brother mathematics. That would have to be omitted from the curriculum, since the English language was substituted for the science. The lessons were given

"in the early morning hours, before the opening of the school and the commencement of military duty." Three years afterwards WILLIAM was sent to Göttingen, where KARL HIMLY, a brother-in-law, was professor of chemistry. He spent about a year in the university, restricting his studies to science, and then his brother was able to obtain a place for him in engineering works at Magdeburg. But he was not destined to remain there for the two years' term which was proposed. With the help of his brother-in-law the chemist, WERNER SIEMENS had perfected a process of electro-plating, for which he took out a patent. England was supposed to be the most profitable field for its exercise; and where could a better agent be found than the young brother who had acquired a Magdeburg version of the language? But cash was required for the voyage, and it was necessary to borrow the modest sum of 100 thalers from a relative. That money, with a few pounds obtained on the way by selling some of the solutions in Hamburg, formed the financial basis of one of the most important houses of our age. WILLIAM arrived in London in March 1843, and, having scanty resources, his first domicile was a little inn called the Ship and Star at Sparrow Corner, near the Minories.

It is unnecessary to say that electro-plating was not then unknown in this country. In 1837 and 1838 SPENCER made experiments in that process, and, as usually happens with important inventions, JACOBI was simultaneously working towards the same end under the protection of the Emperor NICHOLAS. Messrs. ELKINGTON were able to apply the process about 1840, and if we believe the French, it was according to the attempts of their countryman DE RUOLZ. WERNER SIEMENS shrewdly recognised that if he competed it must be under restrictions. He therefore enjoined his brother to ignore colour and beauty of gilding and to restrict himself to simple plating, relying entirely upon the durability of the deposit as laid by the new process.

WILLIAM SIEMENS was advised by a firm of patent agents to bring the process before Messrs. ELKINGTON, and after treating with them through a local firm he went to Birmingham. He then discovered that his brother's prized solutions were actually described in the patent of the firm. But questions of novelty were generously set aside by Messrs. ELKINGTON, and it was decided to judge the new process by a practical test, viz. the deposition with a smooth surface of 30 dwts. of silver upon a dish-cover. He was so far successful that Messrs. ELKINGTON agreed to a patent being taken out at their expense for improvements connected with the deposition of metal, and in the apparatus for that purpose. A sum of about 1,500*l.* was paid to WILLIAM SIEMENS, although the process was not of any great benefit to the firm.

So much money was welcome to the SIEMENS family, and WILLIAM was welcomed on his return as if he were a second JASON; but to a man like WERNER SIEMENS, who knew something of strategy, it was still more important. It revealed to him that Englishmen were ready to pay for the slightest improvements of an invention, and that in his brother he possessed an agent who was at once a commercial traveller and a scientific expert. Is it surprising that another effort was made to gain English money on terms so easy? A project of WILLIAM's for an improvement in the governor of a steam-engine was put into shape with the aid of a practical mechanic, and to it was joined BALDAMUS's or APPEL's process of reproduction, to which the name of anastatic printing was given in England.

In order to dispose of the rights of the two properties, WILLIAM came over in February 1844. He was advised by the Prussian Consul to associate himself with Mr. JOSEPH WOOD, a civil engineer, who took out a patent for the governor, and read a paper upon it at the Institution of Civil Engineers. The value set upon this one invention by WILLIAM SIEMENS was 36,000*l.*, a proof that even in his youth he was not too modest in his consideration of himself. Everything that could be done by interest was accomplished to bring the governor into general use, and improvements were made in it, but up to this day there seems to be a prejudice against it on account of its delicacy. It is considered better adapted to regulate the instruments of an observatory than the machinery of a factory. The anastatic process was not more successful in bringing profit. The value was put down at 50,000*l.*, but as nobody was dis-

\* *The Life of Sir William Siemens, F.R.S., D.C.L., LL.D., &c.* By William Pole, F.R.S. London: John Murray.

posed to buy the rights at that price, an attempt was made to set up an establishment for the new kind of reproduction. The success of the copies is seen in the circumstance that, by the desire of a Committee of the House of Commons, letters bearing anastatic copies of postage-stamps were sent to the members, and the stamps were accepted as genuine by the Post Office examiners. Mr. POLE is evidently unaware of the history of the process. He calls RUDOLPH APPEL, who managed the printing in London, a workman, but APPEL claimed to be the inventor of the process, and the prepared plate was called after him, the *appelotype*. It was he also who invented "the anti-acid and anti-anastatic paper," which he introduced in order to calm the fears of people who believed that the process would give rise to forgeries of all sorts.

The second visit of WILLIAM SIEMENS brought heavy losses in hard cash to many people, and disappointment to himself and his family. In 1845 he seems to have sought employment in connection with one or other of the numerous railway schemes of that year, and a few months afterwards the brothers came to the conclusion that they must give up working the patents for the steam-governor and the printing. The failure was undoubtedly caused by the unreasonable valuation which WILLIAM had placed upon them. It did not strike him that purchasers needed a profit, and he was justly punished for his cupidity. All through his life he was a hard bargainer.

In 1847 WILLIAM SIEMENS settled down in Manchester, where he was engaged by Messrs. HOYTE to devise improvements in calico printing. But his restless brain was not satisfied with that sort of employment. His ambition was to make the steam-engine more effective by its becoming more economical in working. A new theory of heat had been promulgated by JOULE, of Manchester, and WILLIAM SIEMENS was probably the first man who was able to recognise its practical value. He designed a "regenerative engine" and a "regenerative condenser," which were to obtain more efficacy from heat than was practicable with the ordinary steam-engine. FOX & HENDERSON, of Birmingham, undertook to make the engines, and agreed to pay SIEMENS a royalty as well as a salary of 400*l.* a year for his advice. They also agreed to undertake his process for "regenerative evaporation," which was expected to be taken up by salt-workers and sugar-boilers. But the firm soon discovered that the inventions were not profitable. On a French contract for fitting-up salt works there was not only a loss, but the whole machinery was thrown on their hands. WILLIAM SIEMENS, however, took such catastrophes as a philosopher: they were to him only incidents that were of use in his education, and in helping him to make his way in the world. He was enabled to obtain experience in one of the largest establishments in England—for FOX & HENDERSON'S workshops merited that title—and his brother FRITZ was also able to be initiated into English practice at the same time.

Meanwhile WERNER SIEMENS was turning his own attention to applications of electricity. He informed his brother in England at the end of the year 1846 that he was resolved to devote himself to work of the kind, as he believed in its future and felt that he had a mission for it. In the course of the next year he discovered an able mechanic named HALSE, and on the first opportunity entered into partnership with him, his intention being to manufacture telegraphic instruments, signals, &c. But with an eye to the future the works were to be known as a machine factory, and by that title it was hoped all classes of engineering might be introduced. The factory was humble in appearance, but the partners were successful, and in 1851 they removed to much larger premises. It was not long before WILLIAM SIEMENS was asked to become the English agent of the firm.

He was still absorbed with the problem of the conversion of heat into energy, and had worked out more than one solution of it. In 1853 he was able to read an elaborate paper on the subject before the Institution of Civil Engineers, and in 1856 he described his new engine to the Royal Institution. But in the realisation of his theories there were constant disappointments. One of the engines in the Paris Exhibition broke down when the Emperor came to examine it; another, which was set up at Stettin, was ruined by the bursting of a cylinder, and when

SIEMENS went there to ascertain the cause, there was an explosion from which he was glad to escape. A company was established on the Continent to construct regenerative engines according to his system. But it had to be dissolved, for the reports of the engines which were made were too unfavourable, and it was found that the economy was dearly purchased. The old-fashioned engine of WATT was not to be superseded. WERNER was simultaneously trying to improve the apparatus for regenerative evaporation, but he had to confess that the more he did the worse it became, and he had to abandon it.

The failure which attended those applications of the new principles of the theory of heat and energy was happily absent when the improvement of furnaces was taken up. This work exemplified the power of a third brother. Mr. POLE informs us that "during the year 1856 FREDERICK SIEMENS appeared to have conceived the happy idea that the regenerative principle which WILLIAM had been so earnestly striving to carry into effect by complex arrangements of engines and evaporators, might be made available in a much more simple manner by applying it directly to the ordinary furnaces in which the fuel was consumed." The invention was at once a success, and the saving of fuel in iron manufacture alone is estimated at 500,000*l.* a year.

It was not the only success. The water meter which WILLIAM SIEMENS invented was so well patronised as to bring him in 1,000*l.* a year from royalties in Great Britain alone.

But profits of that amount were trivial if compared with those which arose from the telegraphic business of the brothers. WERNER SIEMENS having discovered the applicability of gutta-percha as a covering for the wires, he was able to convince the authorities about the advantage of laying telegraphic wires underground. He was entrusted with much work of that class. It was then only a step to submarine telegraphy, which was further demonstrated by a trial at Kiel. In the English work of the firm WILLIAM SIEMENS was a sharer, and the extent of his work is seen in the setting up of a manufactory of apparatus in London during the year 1858.

The position of WILLIAM SIEMENS in London was now assured. He could not be called presumptuous when he claimed admission into the Royal Society, for his first qualification was as "the discoverer of a law regarding the expansion of steam by heat, and certain properties of insulating materials." The Council placed him among the selected candidates, and he was elected in June 1862.

His twenty years of labour in England only incited him to new tasks. A great improvement was introduced in the regenerative furnace by an arrangement for decomposing the solid fuel and admitting it into the working chamber in a gaseous form. The first of the improved furnaces brought about a saving of 50 per cent. in fuel. The last lecture delivered by FARADAY was upon them. Apart from economy, the furnaces are considered indispensable on account of the intense heat which can be attained within them. The furnaces led to the SIEMENS process for producing steel, for which the first patent was taken out in August 1867. According to it steel could be produced directly from the ore, or by melting cast-iron and scrap-iron, or scrap-steel or blooms of puddled steel and iron in a reverberatory furnace, or the steel may be produced by both processes conjointly. WILLIAM demonstrated its worth by offering to convert the old rolled iron rails of the London and North-Western Company into ingots fit to make good steel rails. He was successful; and again, with the rails of the Great Western Company. Mr. POLE considers that WILLIAM SIEMENS should have stopped there and left the development of the process to others. But, with the aid of a few friends, steel works were established at Landore for the production of SIEMENS steel. Once more the inventor encountered failure. The shareholders, says Mr. POLE, had to submit to great losses, Dr. SIEMENS himself, who made every self-sacrifice to carry on the works, being the principal sufferer.

In 1863 it was found that much larger works were needed for electric work, and plans were prepared for new buildings at Charlton, near Woolwich. In that place WILLIAM SIEMENS was able to display marvellous resource. Mr. POLE suggests the shrewdness of the British workman in taking the measure of an employer or superintendent,

when he relates that it was a saying at Charlton, "that as soon as any particular problem had been given up by everybody else, it had only to be taken to Mr. WILLIAM SIEMENS for him to suggest half a dozen ways of solving it, two of which would be complicated and impracticable, two difficult, and two perfectly satisfactory." It was a summary of character that could not be surpassed. The Charlton works were of great use to WILLIAM SIEMENS in affording him opportunities for experimenting on a grand scale.

The rise of electric lighting offered a new field for the skill of the brothers, and they were as fortunate in it as in other applications of electricity. WILLIAM was concerned in the laying of some of the ocean telegraphs, and, indeed, the loyalty which marked the relations of the brothers was never abated. The position attained by them was not due entirely to their exertions as individuals.

In the latter years of his life WILLIAM SIEMENS was fortunately able to divert some of his thoughts from business. He was engrossed with practice for so long a time as to induce many people, and himself also, to be oblivious of his talent for considering questions in the philosophy of science. In spite of all his losses he could count his profits by hundreds of thousands of pounds, and he might therefore sacrifice some hours for the public good without suffering remorse. He was never likely to forget his works or to abandon profits, but it was plain that if WILLIAM SIEMENS lived, he must have given thought to many things which could not increase his banking account. He felt that he was about to be recognised as an English worthy, and he would be as loyal as if we could claim him as a native. His interest in technical education revealed the breadth of his views and the spirit in which he would judge social problems. England is a loser by his death, for no other man is likely to have so wide an experience in practical science, or could be a better illustration of GOETHE'S wisdom when he advocated an early initiation into the business of life:—"Man kann einem jungen Menschen keine grössere Wohlthat erweisen als wenn man ihn zeitig in die Bestimmung seines Lebens einweiht." The success of the Brothers SIEMENS will be always evidence of the advantage of a right system of technical education. Without egotism, WILLIAM SIEMENS could have pointed to himself as an example of the kind of leader which must be produced if England is to hold her own in the industrial competitions of the future; but the record of his life must now serve as a substitute, and the book by Mr. POLE should receive the careful attention of all who have a desire that England may preserve her position in the world.

#### THE RHIND LECTURES ON ARCHÆOLOGY.

THE third lecture of the course on the Lake Dwellings of Europe, by Dr. Robert Munro, related to the pile dwellings of Italy. The first described were the settlements on Lake Varese, the chief of which is situated on an island known as the Isola Camilla, which is about three acres in extent. Excavations made had resulted in the discovery that the island itself was a large crannog. The remains found in the Varese settlements showed that the series belonged to the bronze age. At one—Bodio—about 200 small silver coins of the Roman Republic had been found, and here too there was a remarkable find of arrow-heads. The stations at Lagozza and Polada, near Milan, were next dealt with. The remains found seemed to indicate that Lagozza came to an end by burning. One peculiarity about this settlement was, that not a single article made of bone or horn had been found, neither was there any trace discovered of any implement used in fishing or hunting. Three arrow-heads were, it is true, got near the place, but their authenticity was doubtful. From these facts it was suggested that the ancient inhabitants of the pile dwellings of Lagozza were vegetarians. Here was unearthed a wooden comb with teeth on one side—the only specimen of the kind found in the lake dwellings of Italy. At Polada, which is situated in a valley between Venice and Milan, the settlement was particularly rich in industrial remains. The pottery, which was all hand-made, was of an interesting kind, the arrow points were well formed, and among a find of 100 flint saws was one in which four separate flints were placed end on in a wooden grooved case, and held in position by asphalt. At one end of the handle was a hole, apparently for carrying the saw; at the other was a long horn-like termination which turned off at right angles to the saws. From the manner in which the implement was set it was concluded that the people

who used it must have been left-handed. The osseous remains found included part of a human skull, which, however, had no distinctive features, and the skull of a cat. There was also found a very fine dagger of bronze, set in a handle of bone, and a curiously perforated tube-like piece of pottery, which, it had been supposed, was used for making cheese. The interesting series of deposits known as the Terra Mare deposits, which had attracted the attention for a good many years of Italian archæologists, were next considered. The mounds in question occur in the provinces of Palma, Reggio, and Modena, and were sometimes about 20 feet in height. For a long time past they had been dug into by agriculturists, who discovered that the peculiar soil of which they were composed formed an excellent manure. In these diggings Roman coins, pieces of ancient pottery, the remains of domestic animals, and even human bones had been found, but little heed was paid to them. The old idea was that these mounds were the cemeteries of successive races, and some countenance was lent to this idea by the fact that in not a few instances the mounds were crowned by a modern church or convent around which interments were made. At Castione, in Palma, a mound which had been excavated there would probably cover about two acres. The discovery of the Swiss lake dwellings turned afresh the attention of Italian archæologists to the Terra Mare deposits, and the finding of piles led some to associate them with the same period. It came to be seen that the mounds had been the dwellings of the living and not of the dead, and the hypothesis adopted by some was that they had been artificial ponds into which piles had been driven, and dwellings erected upon them. But the weak point of this theory was that many of these mounds were far above the beds of the adjoining streams, and that water could not have been raised to them except by hydraulic power. A recent Government commission, which had excavated the mound at Castione, had, he thought, settled the difficulty. These ancient dwellers in the Italian plains had proceeded in this way. They dug a ditch round the place they meant to occupy, and the excavated earth became an enclosing wall on the inner side of the ditch. On the inner face of this wall they drove piles of wood so as to form small hollow squares, the interior of which was filled with sand and gravel. In the space between the two sets of piles they drove short piles, and on the top constructed an open platform, upon which they built their huts. Instead of cleaning, the debris and drainage was allowed to drop underneath, with the rain-water mixed, for the wall being of clay, it could not escape—and so the sedimentary-like character of the layers of different coloured earths which were found in the mounds was accounted for. When the space beneath the huts was filled up with rubbish, the platform was set fire to, and the huts consumed. This was cleaning with a vengeance, but the layers of black charcoal-like substance found seemed to favour the view that this method was adopted, and the inhabitants raising their piles and constructing a higher platform on the top of the old, lived as before until the second space was filled up. The same operation was then repeated, and so the mounds grew, and in some cases they had traces of as many as six or seven of these platforms in a mound. About a hundred of such mounds were known to exist in the provinces named, and they had also occurred in the valley of the Po, but the silting up of the valley by the river, which overflowed its banks yearly, had destroyed most of the traces of them. In the true Terra Mare deposits only articles of the bronze age were found. The Roman remains got were all in the upper portions of the mound.

In his fourth lecture Dr. Munro first treated of the settlements on Lake Neuchâtel, and described that at La Tène, or "The Shallows," situated near to the Gros Moos, through which a channel conducts the water to Lake Bienné. From the investigations made, it appeared that La Tène had originally been an island between two channels of the river Thiele, and it belonged exclusively to the iron age. Not a single trace of any remains belonging to any of the previous ages had been found. The excavations conducted along the filled-up channel of the river had disclosed the remains both of wooden houses and bridges. The section of the cutting gave first a bed of water-worn gravel and sand 3 or 4 feet to as many yards in depth. Beneath that was a blackish mossy bed, which was superimposed on the ancient lake sediment. It was in this mossy deposit, and sometimes buried in it, that the objects characteristic of La Tène were found. The remains found included weapons, implements, ornaments and coins, and from the character of some of these it was conjectured that the station had been a military stronghold of the ancient Helvetians, and that it had been subsequently occupied by the Romans. After a description of a Merovingian settlement on Lake Paladru, which had existed until the ninth or tenth century, Dr. Munro next considered a find which had been made at Maestricht, in connection with a railway cutting made in that locality. No upright piles were found; but the dwellings, which, it was supposed, were the lodges of the hunters, had affinity with the lake dwellings in other places. One of the remains discovered was a portion of a human

skull. There was more than ordinary interest, said the lecturer, attaching to this find, as it was near Maestricht that the celebrated Crahay jaw (now in the Leyden Museum), which was described by Sir Charles Lyell in his "Antiquity of Man" as coeval with a mammoth tusk, was found. The present skull was found from 3½ to 4 mètres below the surface layer of a gravel bed, on which the wooden structure of the ancient dwellings reposed. Mr. Ubaghs found that the two relics were identical as to their patina, consistency of bone, and the position of material in which they were found, traces of which still adhered to them, and he came to the prosaic conclusion that the two belonged to the Maestricht crannog. M. Kerkhoff denounced Sir Charles Lyell for mistakes he had made regarding the relative position of the Crahay jaw and the mammoth tusk. According to Sir Charles Lyell, the tusk was found six yards removed from the human jaw in horizontal distance. It turned out to be neither the fact nor in accordance with the Crahay jaw report, which stated that the former was 7.50 mètres deeper than the tusk. The stone age dwellings at Wismar were next referred to, and the mixed character of the settlements in Germany were commented on. The concluding portion of the lecture was taken up with an interesting description of the Terpen Mounds in Friesland, Holland, which had been found to be identically the same in character as the Terra Mare deposits in Italy. About 150 of such mounds were scattered over Friesland, and, as in Italy, the peculiar soil of which they are made up was largely used by agriculturists as manure. Large quantities of remains were found in these mounds—some of a very mixed character. One which he described from personal observation in Aalsum was about 400 yards in diameter and 20 feet high. A canal had been cut up to it, and from it barges were loaded with the earth for transport to other places as manure. Great care was taken by the diggers and loaders of the remains, which could not be sold until they had been seen by the curator of the museum. Among other curiosities found in the mounds were curiously-shaped narrow conical barrels, with iron hoops, from six to seven feet in length; hens' eggs, with the shells entire. The antiquities included loom weights, spindle whorls, vessels of coarse pottery, Roman fibula, beads, portions of Roman statues, and Samian ware.

The fifth Rhind lecture was devoted to the lake dwellings of Great Britain and Ireland, and at the outset Dr. Munro stated the circumstances of discovery of these lacustrine abodes. It was the discoveries which had been made on the Continent which had first drawn attention to similar remains in this country, and although as far back as 1812 Mr. John M'Kinlay had observed what were supposed to be the remains of a crannog in the island of Bute, it was 1857 before the subject was brought under the notice of the Society of Antiquaries. In that way inquiry had been stimulated, and various remains had been brought to light, chief among which Dr. Munro mentioned the crannogs at Dowalton, Lochlee, Buston, and Lochspouts—all in the counties of Ayr and Wigtown. Similarly he described the progress of discovery south of the Border, mentioning, at the same time, as a singular circumstance, that it was on the crannogs in Ayr and Wigtown that archaeologists were almost entirely dependent for their facts. All the wooden islands hitherto examined in Scotland appeared to have been built on a uniform plan, the main object of which was to give stability to the island, to afford fixed points on its surface, and to give a base for the buildings which were erected upon it. The topographical requirements seemed to have been a small marshy lake, secluded in the primeval forest. As to the manner of construction, it was obvious that heavy substances, such as stones and earth, would have been inadmissible, owing to the soft bottom of the loch. Accordingly, the general plan was to construct an island of fascines, stems of trees, and brushwood, laid transversely and mingled with stones and earth, the mass being pinned together towards the margin by a series of stockades, which were firmly united by intertwining branches, or in the more elegantly constructed crannogs by horizontal beams, with morticed holes to receive the uprights. These horizontal beams were arranged in two ways—some laid along the circumference, and bound together by all the uprights in a circle, while others took a radial position. Frequently a wooden gangway stretched to the shore, and these were sometimes ingeniously constructed. The great value of the investigations, however, lay in the great quantity and variety of the remains of human industry which had been brought to light in the investigation of these crannogs, and of these Dr. Munro went on to give some account. At the Lochlee crannog these had included glass beads, regarding which Dr. Munro had come to the conclusion that they were entirely Roman. There were also bronze fibulae, certainly of Roman origin; bronze leaf-shaped spear heads, which were very rare; querns, which were numerous in the British lake dwellings as distinguished from those investigated on the Continent. At Lochspouts there had been found a bridle-bit, a cross enclosed in a circle of metal, along with a crystal found in the same crannog,

supposed to be of Christian origin, and the only objects of the kind found in any of these dwellings. At Buston, gold rings had been found, and a portion of a curious lock; and at Dowalton the discoveries had included finely-shaped vessels of Roman origin, shoes, also apparently of Roman origin, beads, ornamented combs, pins, &c. Along with these there had been found at every one of the crannogs numerous weapons, domestic and other utensils; and Dr. Munro went on to consider what information could be gleaned from the remains regarding the original inhabitants of these dwellings. There could be no doubt, he said, that the inhabitants of these crannogs had come into contact with the Romans, although in the remains the Celtic characteristics were strongly developed, and the ornamentation was of a kind peculiar to Celtic art. The nature of the remains—mostly of the Domestic kind—were sufficiently indicative of the peaceful character of the lake dwellers. Military remains were but feebly represented. That many of the relics were the product of a refined civilisation was not more strange than the circumstances in which they were found. He thought there could be but one hypothesis, namely, that the lake dwellings in the south-west of Scotland were post-Roman, and had been constructed by the Celtic inhabitants as a means of protection when, from the frequent withdrawal of the Roman soldiers, they were left to defend themselves from the Angles on the east and the Picts and Scots on the north and west. Their military tactics would assume more the character of defence, and in order to escape from the marauding inroads of these tribes, experience had taught them the value of that mode of refuge. With their complete subjugation the function of these lake dwellings had ended. Dr. Munro passed to discuss in the same way the existence and discovery of lake dwellings in Ireland, commencing with the first notice of these after the discovery of the crannog at Lagore, Westmeath, in 1839, which archaeologists had assigned to a date in the tenth century. He showed how far subsequent investigation had disclosed the existence of these in Ireland, so that in 1885 the total number was stated to be 221. He showed how these were similar in structure and character to the Scottish crannog, and then went on to discuss the general question as to the prevalence of crannogs among the Celtic tribes in Britain, and the question whether they were of Celtic invention and the outcome of its peculiar civilisation. Speaking generally, he thought they were fragments of a wider custom, and that the system was derived from the Swiss lake dwellers, whose admirable system must have attracted the attention of the surrounding races. The early Celtic immigrants into Britain must have been acquainted with the advantages of these lake dwellings—a knowledge which they retained long after the system had fallen into desuetude on the Continent. It was as defenders, not as conquerors, that the Celtic inhabitants of Scotland and Ireland constructed their lake dwellings; and as to the structural difference between the pile dwelling which was common on the Continent, and the fascine dwelling which prevailed in Britain, he pointed to the evidence of both systems having been known both on the Continent and in Britain, while in Britain the artificial islands supplied more readily, and with less labour, the requisite stability. He saw no *prima facie* improbability against the hypothesis that they were the outcome of a system which was developed in Central Europe.

#### "MADE-UP ROADS."

THE vagueness which characterises the common phrase "made up" as applied to roads was exemplified in a case that was heard by Mr. Justice North on Monday. A piece of land situate about a mile from the Worcester Park Station, containing over twenty acres, was sold as building land for 1,500*l.*, or 7*o**l.* an acre. The descriptive particulars stated that a new road over the estate was made up and sewered. The expression "made up" was used in more than one place in reference to the road, and the road was also stated to be in continuation of Chedington Avenue, an existing road. The road across the property sold was about 350 yards in length. Some ballast had been put upon it. It had a path, but it had not been metalled. Chedington Avenue was gravelled, with a foundation of chalk instead of ballast. The sale was made shortly after an abortive auction under conditions of sale prepared for the auction. The purchaser had not seen the property when he bought it. There was a condition that a misdescription should not annul the sale, but entitle the purchaser to compensation. The vendors contended that there was no misdescription, and refused to allow any compensation. The purchaser, on the other hand, insisted on the right to have the road put in such a condition that it would be ready for the local authority to take it over, which, he contended, included kerbing and channelling, with two paths, or to have the amount of the cost of doing the work allowed him.

Mr. Justice North, in examining the evidence as to the technical meaning of the expression "made up," said that he

had no less than five different views presented to him by the surveyors who had made affidavits, varying from the view of a witness on the part of the vendors, who considered that a road was made up when it had been put in the state in which this road was, to the view of a witness on the part of the purchaser that the words implied that the road was in a fit state to be taken over by the local authority. His lordship pointed out that such a description as the last did not afford a clear guide on which to act, for the requirements of different local authorities were different. He was of opinion that there was no general meaning of the expression which the Court could adopt. But looking at the construction of the whole particulars, he came to the conclusion that the meaning of the words as used in the description of the property, taken with their context, amounted to a statement that the road was made up in the same sense that Chedington Avenue was. That being so, there remained the question of what compensation the purchaser was entitled to. He claimed to be allowed the whole sum that it would cost to put it in the state it was represented to be in. His lordship was of opinion that that was not so. The vendors might, if they pleased, put the road in the state in which it was represented to be, and thus satisfy their contract; but they were not bound to do so, and he did not consider that was the measure of the compensation they were bound to pay. In his opinion the measure was the difference of the price agreed to be given and the decreased value in consequence of the road not being made up. It might be that because the land was to be used either as pasture or building land in the one case the road would not be required, or in the other, if made up, it might be so cut up by building operations before it was taken over that it would require to be remade. His lordship directed an inquiry at Chambers to ascertain the damages sustained by the purchaser.

### TESSERÆ.

Truth in Architecture.

S. SMIRKE.

PAINTING and sculpture are so fortunate as to have in nature a standard of excellence for ever before them, a frequent recurrence to which keeps them on their own true course. But architecture is less able to draw her inspirations from that pure source: her wants are too artificial; she is too dependent on the requirements of man to enable her to look implicitly up to nature. But architecture still has a ruling principle, which is truth. From Vitruvius downwards this has ever been taught, although in practice it has often been grievously disregarded. There is an honest simplicity—a plain manliness—about truth which wins our regard, whether in ethics or æsthetics. But whilst we recognise truthfulness as a cardinal virtue in our art, as well as in morals, we must take care not to allow that analogy to carry us too far. We often meet in the practice of our art with necessities utterly inconsistent with beauty. Hard lines, unsightly angles, heavy, graceless forms, imposed on us by structural requirements; it would be a mischievous error to suppose that, because in our social conduct there should be no deception nor concealment whatever, we are therefore bound to expose to view these mechanical deformities from which we cannot escape; whilst to depart from the form that is mechanically the right form, only to make it more agreeable to the eye, would be a still graver error. That there should be a politic concealment sometimes studiously resorted to, some ingenious art practised occasionally—such, for example, as the concealed buttresses and the hidden ties and props common in old buildings—seems therefore to be an unavoidable condition of our calling. In the most natural-looking schools nature is not, and never has been, copied with a stern adherence to exact truth. The simplest leaf requires treatment to fit it for the purpose of decoration, and treatment implies some modification or humouring of form or of colour; in short, some departure from nature and consequently from truth. Nearly allied to this is another principle of our art, which although by no means universally acted upon, yet justly claims our most respectful submission. We should have a care how we introduce into our design anything which does not serve some good purpose. I do not mean that mere utility would justify a deformity, nor do I mean that every architectural feature in our design should be a structural necessity; but that, although it may not be to add strength or to afford support, it should at least have its appropriate purpose: a valid reason should be assignable for it; some good end must be sought to be attained by it; some offensive angle or feature to be removed; some unsightly blank to be relieved; some monotony of line to be broken; some needed light or shadow to be introduced; some discord in form or colour to be allayed.

### Cruciform Churches.

A. H. DIDRON.

In the West the churches are usually in the form of the Latin cross of unequal parts, the apex and arms being shorter

than the shaft or trunk. The foot or shaft forms the longitudinal nave, the arms form the transept or transversal nave, the apex forms the choir. In the Middle Ages the choir was shorter and the nave longer. In the basilicas of Constantine the transverse nave (called the transepts or cross aisles) cuts the longitudinal nave immediately adjoining the apsis, it leaves no room for the choir. In the thirteenth century the choir lengthens and forces the transept towards the west. There are even some churches in which the transverse nave is nearer to the portal than to the apsis, so that it is still a Latin cross, the divisions being unequal, and the cross aisle cutting the transverse nave into two unequal portions, but it is a Latin cross reversed, the apex of which is longer than the pedestal. The church of St. Germain l'Auxerrois at Paris is of this form; from the portal to the transept the nave is four widths in length, from the transept to the bottom of the church the distance is nine widths; the top, which ought to be much longer, is really shorter than the bottom: the arms are short, as is usual in the Latin cross, only occupying three widths between them. Many of the English cathedral churches have a form which is neither that of the Latin cross nor of the Greek cross, nor even that of the simple tau. These singular edifices are divided not by one transept but by two. The first cuts the longitudinal nave in half; the western or inferior end forms the nave properly speaking, and the eastern end forms the apsis of the church; this apsis itself is divided by a second transept, usually shorter than the first. On this side, viz., from the first to the second transept, is the choir; on the other, viz., from the second transept to the bottom of the church, is the sanctuary. The cathedrals at Salisbury, Lincoln, Beverley, Rochester, and Worcester are of this character. Let a figure be drawn of the Cross of Christ, with a long and wide label attached to it bearing the inscription "Jesus of Nazareth, King of the Jews." This label, as it were, is adopted in English churches, and forms the eastern transept, that which divides the top of the cross into two parts; then comes the usual cross aisle or transept, on which the arms of Christ were extended. This is derived from the Cross of Lorraine, the Cross of the Knights Hospitallers, and from that which denotes at present the archiepiscopal dignity, it is the double cross; it seems to be borrowed from Greece, for we meet with it frequently in Attica, in the Morea, and at Mount Athos. The designs for churches in the form of a cross were often revealed in visions. In the night an angel appeared to a sleeping saint, perhaps to a bishop, and made known to him the form of a monument which was to be erected by the command of God; immediately the work was put in hand according to the model seen in the dream. Sometimes bright lines were observed in the sky, tracing on the clouds the form of the church to be erected. In this way Constantine caused his Labarum to be executed in the form of that which he had seen traced in lines of fire in the sky, and according to which luminous design the edifice was erected. Sometimes the plan and form of a basilica might be discovered traced with drops of dew on the dry ground, at another time it was the snow which indicated the spot and marked the form in which the walls should rise. Thus the French abbey and church of St. Michael in the department de la Manche, and the Italian church St. Michael at Gargano were traced upon the earth by the steps of a bull.

### Fifteenth-century Glass.

T. GAMBIER PARRY.

The improvements in the arts of painting during the fifteenth century were the first poison-drops which ultimately ruined the art applied to glass. Up to the end of the fourteenth century little harm was done. Shadows were used in the draperies, but they were used as they ought to be—for glass. The folds were marked, as in the previous style, by strong and fine lines, the shadows in the fewest possible places so darkened as to save the rest from weakness. The points in the figure composition and the relief of the parts were maintained in the genuine spirit of glass-painting, by the contrast of colours and the shapes of the pieces, and pre-eminently by the reckless boldness of the leading. Too much praise cannot be bestowed on the care that was lavished on the ornamental as distinguished from the pictorial parts. It is a great mistake to suppose that a high and refined sense of beauty can only be shown in figure-painting. Ornamentation is to art what the varieties in form and tint of leaves and flowers are to nature, and often expressive of its great beauty. It is a branch of art never despised by the really great artist. The principle of an arabesque, if only used in the right place, is admirable. The Early Gothic and Norman arabesques were magnificent. There is just in them that legitimate place for wild fancy which is wanted somewhere—a sort of safety-valve for fun which must break out somewhere, and might otherwise become dangerous. About the middle of the fifteenth century the treatment of pictures in glass became more and more relaxed. The artists had hitherto been guided by the safe principle of deference to the architecture of which their work formed a part. After that time the architect's design seemed to be beneath the notice of

the painter's condescension. He spread his pictures over the whole window-space, regardless of all obstacles. A little later than this a magnificent style of glass-painting was developed in Italy. Glass was treated pictorially indeed; but, like most genuine artists as they were, the Italian designers of those pictures felt intuitively that the compositions and resources of other styles were unsuitable for glass. So they went in for light and colour like men; and designed, for breadth of contrast and vigour of effect, figures, architecture, fruit, flowers, animals; and then leaded them altogether, regardless of atmospheric effects and perspective, and with an equality of colour throughout and relief in the detail just enough to save all the objects from confusion. The effect was the most powerful that glass could produce. It was flat, architectural, and grand in the extreme. The success of those windows consisted in this, that their designers were, first of all, consummate artists themselves, and then that they had the genius and wit to seize the true and complete idea of the materials they had to work with. There was the last blaze of that fine art for many a long year. Their successors adopted a new system by painting upon glass with enamel colours. The result was the rapid decline of the art. They would paint. The art of glass, therefore, was no more.

#### Park Roads and Garden Walks.

J. HUGHES.

In gentlemen's parks, gardens, and pleasure grounds it is exceedingly difficult, if not impracticable, to make ornamental carriage roads or private walks by the old system of laying on loose gravel or broken stones; for whatever pains be taken in selecting the best kind of gravel, and afterwards in forming and rolling, worms will find their way through and destroy it by depositing a portion of adhesive earth wherever they work to the surface; and these deposits are so numerous, particularly in the autumn and through the winter and spring of the year, that in the case of the carriage-roads this earthy material first adheres to the rims of the wheels, and then again sticking to the gravel, tears up the whole surface to the entire destruction of the road. Garden walks from this cause frequently cannot be traversed with any pleasure: the dirt adheres to the feet, and is so exceedingly unpleasant that such roads and walks, instead of having a hard, clean, and smooth surface, become dirty and unsightly in the extreme. I would recommend in such places that the roads and paths should uniformly be made with a concrete bottom of only a very few inches in thickness—say three inches for carriage-roads and two inches for paths, and with a slight covering of binding gravel on the top. This system, I think, would effectually prevent the roads from being destroyed in the manner I have described; for, independent of the antipathy which the worm, and I may add every description of insect, entertains against lime, and notwithstanding their capabilities of boring, they never could penetrate half an inch into the concrete. As an instance of the perseverance of worms and the mischiefs they sometimes occasion, I have myself, during a very dry hot summer, met with them in canal excavations, four feet below the surface, in hard clay; and I have known them penetrate afterwards out of this depth, and through three feet of clay puddle, thereby actually occasioning leakage in the canal.

#### Italian Gothic.

W. BURGESS.

Much—very much—is to be learnt from Italian Mediæval architecture, but its details by no means suit it either for our climate or materials; and although certain things may look exceedingly well executed in marble in the half-Oriental town of Venice, it hardly follows that it should do so executed in soft stone, and placed in a street of some provincial town. So much is this the case that I am half afraid that nearly all our faults in modern architecture may be traced to the misuse of Italian examples. Of course, Italy is a delightful country to study in, and replete with all sorts of associations, and it is far more pleasant to make a tour which shall include Florence, Venice, and Rome, than to spend week after week in a dull town like Chartres. When, therefore, it was found that Mediæval art could be studied in Italy, students of the new school flocked thither, and, wishing to bring back telling sketches (the curse of architecture), copied the details, which ought not to have been copied at all, forgetting to study the great broad masses, the strong unchamfered angles, the beautiful figure sculpture, or the wonderful frescoes. It may be asked, What has an architect to do with sculpture or frescoes? I repeat that, unless he can give small drawings sufficient to show what groups or figures he wants, and what those figures are to do, he only knows one-half of his profession, and has only half a claim to be considered an artist. The same with regard to the frescoes: he should know how to dispose of them in the building; how to separate them by bands; how to allow for height of situation; and, in fact, be able to give every assistance to the painter actually employed in their execution; and for all this he must know how to draw the figure tolerably. But if

he has studied these things, and can draw the figure tolerably, he will be able to make the building interest the spectator, and tell wondrous stories without a moulding or piece of foliage in his architecture. It was to this that Mr. Ruskin alluded when he said that a square yard of stone was sufficient for any man to show what was in him; and, so far as I may be permitted to say so to such an authority, I consider Mr. Ruskin to be thoroughly in the right.

#### Formation of Granite.

SIR C. LYELL.

The study of late years of the constituent parts of granite has led to the conclusion that their consolidation has taken place at temperatures far below those formerly supposed to be indispensable. Gustav Rose has pointed out that the quartz of granite has the specific gravity of 2.6, which characterises silica when it is precipitated from a liquid solvent, and not that inferior density, namely 2.3, which belongs to it when it cools and solidifies in the dry way from a state of fusion. But some geologists, when made aware of the intervention on a large scale of water in the formation of the component minerals of the granitic and volcanic rocks, appear of late years to have been too much disposed to dispense with intense heat when accounting for the formation of the crystalline and unstratified rocks. As water in a state of solid combination enters largely into the aluminous and some other minerals, and therefore plays no small part in the composition of the earth's crust, it follows that, when rocks are melted, water must be present, independently of the supplies of rain-water and sea-water which find their way into the regions of subterranean heat. But the existence of water under great pressure affords no argument against our attributing an excessively high temperature to the mass with which it is mixed up. Still less does the point to which the melted matter must be cooled down, before it consolidates or crystallises into lava or granite, afford any test of the degree of heat which the same matter must have acquired when it was melted and made to form lakes and seas in the interior of the earth's crust.

#### Roman Bricks.

J. TURNER.

They had several sizes of bricks, one of which they called bipeda, or 2 Roman feet long; another, didoron, about 6 inches broad and 1 foot long. In Palladio's time artificial stone or bricks were called quadrels, and, according to Pliny, those chiefly used were a foot and a half long and a foot broad, which also agrees with the size mentioned by Vitruvius, though Alberti says, "We see in some of their buildings, and especially in their arches, bricks 2 feet every way." He afterwards remarks that in several of their structures, particularly in the Appian way, were several different sorts of bricks, some smaller and some bigger, and he mentions having seen some not longer than 6 inches nor broader than 3 inches, and 1 inch thick, but these were chiefly used in their pavements and edgeways. Palladio observes, bricks may be made bigger or smaller, according to the nature and quality of the building, and the use to which they are designed. They also made bricks of other forms than those enumerated. "I am best pleased," says Alberti, "with their triangular ones, which they made in this manner; they made one large brick a foot square and an inch and a half thick; while it was fresh they cut it in two lines crossways from one angle to the other, which divided it into four equal triangles. These bricks had the following advantages: they took up less clay; they were easier to dispose of in the kiln and to take out again; they were more convenient for working, because the bricklayer could hold four of them with one hand, and with a small stroke divide the one from the other; when placed in the wall they appeared like complete bricks of a foot long. Some of these bricks are to be seen in the walls of Rome, particularly that part built by the Emperor Aurelian." Hope speaks of bricks being made in the form of lozenges, and some were even moulded, or were, after being cemented together in regular layers, carved out into every variety of architectural ornament, as we see at Rome in the remains of the Amphitheatrum Castrense, of the temple of the god Ridiculus, and in another building, where even the capital and foliage of the Corinthian order are cut out of solid masses of brickwork. With regard to the method of manufacture, we learn from Vitruvius that a red or chalky white earth, of a strong sandy nature, mixed with straw, was considered the best, on account of its not being heavy, which it was thought better to dig in the autumn, and make it into brick early in the spring; after they were moulded they were placed in the shade to dry, and, when made properly, they were not put into the kiln for two years afterwards. Alberti says the ancients mixed marble with the red earth; and it was also customary for the Romans as well as the Egyptians to inscribe and impress their bricks with various devices. In the bigger sort holes were left, that they might dry and burn better.

## NOTES AND COMMENTS.

ACCORDING to the diary of JOHN THOMPSON, of which a portion appears in an American magazine, we must henceforth recognise CARLYLE as one of the admirers of WREN as an architect. One night in October 1864, CARLYLE walked with THOMPSON from Chelsea to Pimlico. "On the way," says the diarist, "passing Chelsea Hospital, he burst into a tribute to WREN, the architect, of whom he said there was a rare harmony, a sweet veracity, in all his work." There was a limit to CARLYLE'S wanderings, for if he had gone so far as to behold the outside of St. Paul's, and had ever ventured inside in the daytime, he must have known that the sweet veracity could at times become sweet shamming. The strange thing in the passage is the assumption of the office of art critic by CARLYLE. At one time he maintained that we ought to be silent about the qualities of a work of art. When he was writing upon WREN some thirty years before, he evaded an estimate of WREN'S St. Paul's as a work of architecture. He cited it as an example of what could be done by a man who was able to wrestle with "the stern brute powers of fact." The virtue was not in the harmony or the veracity of the building, but in the overcoming of foolish unarchitectural bishops, red-tape officials, idle NELL GWYNNE defenders of the faith, mutinous masons, and Nature herself, "who carries her mathematics and architectonics not on the face of her, but deep in the hidden heart of her." It was not the artist, but the brave man who obtained the commendation. CARLYLE may have based his estimate of WREN on the Chelsea Hospital alone, a building where it was difficult to be unvarnished; but, in any case, it is satisfactory to discover that he could condescend to praise an architect's work.

It is a fatality that whatever is done to make life more endurable creates new demands for the exercise of medical skill. Sanitarians, for instance, have been looking forward to the time when gas illumination would be superseded by electric lighting. It is found, however, that the latter has created a new malady, which for the time is known as electric prostration. According to the *Lancet*, several cases are reported from Creusot, in France, the sufferers being the workers in the great factory of the Schneider Company. The light exceeds 100,000 candle-power, and it appears that it is this excess of light, and not the heat, which produces the nervous symptoms. "A painful sensation in the throat, face, and temples is first noticed, then the skin becomes coppery red, and irritation is felt about the eyes; much lacrymation ensues, and these symptoms then disappear, whilst the skin peels off in five days. The effects are comparable to those produced by walking over fresh snow in the sunlight, and may be regarded as a sort of 'sunburning.'" Probably there are causes in Creusot which contribute to the illness. It is not uncommon to find people who work under the electric light for a long time becoming brown, as if they were exposed to the sun's rays; but hitherto it was supposed that the colour was an indication of a favourable atmosphere.

M. GRAU, of Vienna, has discovered a series of portraits in Egyptian tombs, which are in a condition that surprises every one who has seen them. Although they are at least two thousand years old they seem to be as fresh as many more modern works in oil. They are painted in encaustic. Altogether there are about seventy portraits of men and women; some are on wood panels and some on canvas. It might easily be supposed that they are counterfeits by some living artist, but Herr EBERS, the Egyptologist, and Herr MENZEL, the painter, have expressed a belief in the authenticity of the portraits.

THE fifteenth annual competition between the various sketching clubs of London was held on Wednesday, in the rooms of the Royal Society of British Artists in Suffolk Street. The judges were Mr. FRANK DICKSEE, A.R.A., Mr. THOMAS BROCK, A.R.A., and Mr. DAVID MURRAY, A.R.S.A. The award of honour was given to the Heatherley Sketching Club, which gained also six out of the twelve competitions for the excellence of the works submitted.

The first, second, and third prizes for figure fell respectively to TOM TAYLOR, KATE STREET, and M. CLIFFORD, all of the Heatherley. The following awards were also made:—For landscape, E. A. ROWE and E. FOX, of Lambeth Schools, and Miss HOMAN, of the Heatherley. For animals, Miss SOWERBY, of the Union Club. For design, P. KEMP, of Lambeth, and Miss HOMAN, of the Heatherley. For sculpture, J. R. ESSEX, of South Kensington, A. LUCESI, and H. FEHR, of the Royal Academy Schools.

THE Finance Committee of the London School Board have reported that, in consequence of the improvements which are now made in the erection of schools, the loan at present sanctioned by the Education Department is insufficient to cover the cost of schools in London. Among the improvements which cannot come within the 10% per head normal rate are the plastering of walls and class-rooms, cement dados, facing staircases and corridors with glazed bricks, providing a hall for each department, and a drawing class-room in every school, arranging covered playgrounds with a view to their conversion into technical class-rooms or workshops, providing more efficient heating, hot-water apparatus, and extra grates in case of its failure, being now found in each school. In the pupil-teachers' centres (for which a loan of 1% per foot superficial of floor space is allowed) the walls are now plastered, and the walls of staircases and corridors are lined with glazed bricks; and, in addition, there are also provided open and covered gymnasias on the top of the buildings. The Committee recommend that a letter be sent to the Education Department calling attention to the additions, such as the above, which are now a necessity.

As the stage presents a representation of life which is never truthful, we must not wonder if actors, when they pose as historians, should also have a leaning towards fiction. Mr. WILSON BARRETT was invited on Saturday evening to the Art Club in Liverpool. He tore a passion to tatters for the amusement of his hosts, in this style:—"To some kind of men the very word 'art' is in itself offensive. It is a red rag, the slightest flutter of which is madness to the Philistine bull. How he will snort and stamp, foam and fret, rage and roar at the mere sight of it. Like other bulls, he is ready to toss and gore all within his reach, and like them he could not for the life of him tell why. Actors, authors, painters, we are now told, are over-paid, over-praised, over-petted. As if genius was ever over-paid, or could be over-valued! Over-paid, indeed! So said the canons of Parma, who docked one-half the price charged by ANTONIO of Correggio for his glorious fresco—the *Assumption of the Virgin*; docked it one-half, and then added insult to injury by paying that half all in copper. So that, having nearly broken his heart by this want of appreciation, they tried to break his back by the underpayment. Where are these depreciators now? Their very names are forgotten, and only the record of their meanness remains. But CORREGGIO lives still. As he himself expressed it, he had thoughts at the end of his pencil—thoughts which burn as freshly now as they did four centuries ago in the little Tuscan village where he was born, existed, was misunderstood but painted, was despised but painted, starved but painted—painted himself into the hearts of generations to come, living ever, teaching always." The Art Club, it is needless to say, is not an artists' club, and the hosts were on an equality with the guest in their knowledge of the history of Italian painters, for not one of them rose to suggest that all Mr. WILSON BARRETT'S pity was wasted over a narrative that was not true. Liverpool is, we suppose, the only place in England where a man could get excited over the woes of CORREGGIO. The absurdity of the story was demonstrated years ago; and no other proof is needed than the joyousness which is found in CORREGGIO'S pictures. It is evident from them that he was among the happiest of men. Let Mr. WILSON BARRETT put one of the translations of OEHLenschläger's "Correggio" on the stage and we will applaud him in the title rôle, but we beg of him for his own sake to keep from orations on the history of art unless on occasions when he finds himself in the Liverpool Club. There he cannot be too wild in statement.

## ARCHITECTURAL ILLUSTRATION SOCIETY. SECOND SERIES.

NO 36.—HOUSE, PALACE COURT, KENSINGTON. [LEONARD STOKES.]

MISSION CHURCH, ROUNDHAY ROAD, LEEDS.

WHEN it was decided, in connection with the Leeds Church Extension Society, to form a new church district in Roundhay Road, taken partly from the parishes of St. Clement's, St. Martin's, and St. John's, Newtown, three firms of architects were invited to submit plans, and we publish to-day the designs prepared by Mr. T. BUTLER WILSON, architect, of Leeds and Harrogate. Accommodation is provided for 400 persons, at a cost of 1,000/.

FIREPLACE, SWAN INN, KNOTTINGLEY.

THIS fireplace is 7 feet 10 inches wide and 10 feet 6 inches high. There is uncertainty about its origin. In the centre, it will be observed, is a shield with arms, which should be a clue in the inquiry, but it has failed in that respect. On the top is the god PAN, and the figures at the sides suggest pastoral pursuits. The frieze is of the same character, and in one part a wolf is introduced with a lamb on his back.

The plate is taken from Mr. BULMER'S "Architectural Studies in Yorkshire," which contains representations of valuable fragments of ancient work, besides a map of the county, showing the railway approaches to them. A copy of the volume was accepted by the Queen.

PROPOSED CORN EXCHANGE, ALNWICK.

THE execution of this design is deferred owing to difficulties regarding the acquisition of a site. The design shows the Corn Exchange, which will also be suitable for holding concerts, &c., on the first floor, and shops on the ground floor. The large hall could be readily emptied in case of panic by means of its three staircases, and the building is designed so as to be fireproof throughout. Mr. GEORGE REAVELL, jun., of Alnwick, is the architect.

## ST. MICHAEL'S, COVENTRY.

A MEETING of the Restoration Committee of St. Michael's Church, Coventry, was held in St. Mary's Hall, on Thursday in last week, for the purpose of considering Mr. Scott's amended plan and the estimate for work at the east end of the church, the question of the groining of the tower, and hanging the bells.

The following report by Mr. John O. Scott was read:—  
Gentlemen,—As notice has been given that, at the next meeting of the general committee on Thursday next, the question of ordering the stone groining in the tower will be raised, and as this seems to involve the larger question of the bells, I think it may be useful for me to send a statement of my own opinion and of those which have been expressed by others on this subject. I have before me a copy of a letter written in 1851, by the late Sir Gilbert Scott, to Mr. S. Vale, of Coventry. It is chiefly an appeal for the restoration of the interior of the tower. He writes:—"The whole interior of that magnificent tower was originally open to the church, and visible from within to a height of about a hundred feet from the pavement. The walls are throughout ornamented with niche work, and the windows are as richly moulded within as without, while the whole was closed in overhead with a beautiful groined vaulting of stone, thus forming altogether a most magnificent open lantern, probably nearly (or quite) the finest in England." He goes on to advise the taking-down of the great timber framework, and rehanging the bells in the chamber above the groining, so that the whole of the lantern might be thrown open to the interior of the church.

It requires but little consideration to see that this position for the bells could only be suitable for chiming, as opposed to ringing them in peal, for if the lantern were opened as my father so strongly urged, there could be no ringing chamber at all, the entire height of the tower being open and without any floor, from the stone vaulting to the pavement. My father's recommendation can therefore refer only to chiming the bells, and I will say at once that I am of the same opinion, that if the people of Coventry are satisfied that the bells should in future

be chimed only, I see no reason why they should not be placed above the stone groining.

In reading the reports drawn up by Sir Gilbert Scott, it is important to bear in mind that the shattered condition of the tower and its serious inclination from the perpendicular were not ascertained at that time—nor indeed till the scaffolding was erected four years ago.

That this is so is proved by the fact that my father speaks only of the disintegration of the stone owing to the action of the weather aggravated by the vibration of the bells. Neither the settlements nor the inclination towards the north-west are mentioned by him.

After the actual condition of the tower had been ascertained at the end of 1885, the opinion of Mr. Pearson was asked for at my request. His report is dated December 21, 1885. It concludes by advising the entire rebuilding of the tower as the best course to adopt, though he previously speaks of the tower becoming strong enough for the bells, provided that it was strengthened by the additional masonry which I had recommended.

It will be well to place by the side of Mr. Pearson's report the letter which has recently appeared in the *Times* from Lord Grimthorpe, as his opinion seems to agree with Mr. Pearson's. He finds great fault with all concerned for not having rebuilt the tower with larger buttresses. He states that if this had been done the bells could have been rung in it with perfect safety, clearly implying that the tower as it now stands is not strong enough to receive the bells. This opinion is of much importance, as no one knows more of the effect produced by bells than Lord Grimthorpe.

The sub-committee have a letter from Canon Cattley, of Worcester, who stands only second to Lord Grimthorpe in his knowledge of bells and their requirements. His opinion is as follows:—"If the recent work only includes a recasing of the old, without any additional buttresses, it would be folly to place the bells as before; the thrust of that heavy weight of metal is enormous, the old troubles would again soon show themselves, and the same anxiety would ensue. If that splendid offer towards a new bell-tower still holds good, I hope the authorities will accept it."

Canon Cattley is of opinion that even chiming the bells would be injurious.

That the tower of St. Michael's was not originally intended to carry a heavy peal of bells is shown by the fact of their being no ringing chamber provided, except indeed the room above the groining. It would appear that the bells were at first hung in the octagon storey below the spire, where the corbels for the beams still remain. That the bells hung in such a slightly built structure as this is must have been of very light weight is certain. This peal was hung in the year 1429.

There are various records of the bells being added to and recast, and probably at some period they were placed in the chamber above the groining, in which position they must either have been chimed or rung from some stage inserted in the lantern below.

The present peal of bells was contracted for and erected in 1774, and the following significant paragraph relating to them occurs in Sharpe's "History of Coventry":—

"The apprehension of injury to this beautiful tower and spire became so general after the new and enlarged peal of ten bells was hung in 1774, that a committee consisting of the neighbouring noblemen, gentlemen, and principal inhabitants of the parish, was appointed on June 19, 1793, to examine into the state of the tower, and conduct the necessary repairs.

"On July 17 following, the late Mr. Wyatt and Mr. Potter, of Lichfield, attended the committee, and gave their decided opinion that the bells had been a considerable injury to the tower, and would continue so whilst in their present situation."

It was after this report, and only nineteen years after the peal of bells had been hung, that they were taken down and the structure of timber erected to carry them, as it was hoped, independently of the tower itself; at the same time extensive repairs were carried out, "the decayed and fractured stones being taken out and replaced by new ones, and strong bands of iron let into the stone at different intervals, thus rendering the fabric, in the opinion of the architect, as strong as when first built." It is not necessary to pursue the history of the bells any further, as it is familiar to all how, in spite of all that was done at this time at a great expense, "to make the tower as strong as when first built," the mischief went on getting worse and worse, till the present greater work of restoration was begun in 1885.

No one doubts for a moment that if the tower had been entirely rebuilt and its walls and buttresses increased in strength, as advocated by Lord Grimthorpe, it could have been made strong enough to bear the strain of the bells, but to have done this would have been to alter the beautiful design to a very serious extent, and the opinion of the committee was absolutely against this. Even the small addition to thickness of two of the walls recommended by me was not entertained, and a resolution was unanimously passed to restore the tower

exactly on its own lines. This determination was come to by the committee with the full knowledge of what Mr. Pearson had just reported, and also that both the architect and contractor had expressed the opinion, that while on these lines the tower could be made perfectly secure, it would not be able to bear safely the strain of bells ringing in peal.

The opinion which I then expressed I still hold. The tower was never designed to bear any such strain. Its walls are thin, its buttresses very light, whilst its stonework is pierced by a larger number of openings than can be found in any other steeple.

It is these features which give it its wonderful beauty and grace, but at the same time they deprive it of that immovable strength which is essential in a bell tower.

No doubt we have substituted a good foundation for a bad one, and have faced the tower with a hard and durable stone. We have also bonded the cracks and repaired all the settlements. But the weakness inherent to the design remains; the tower still inclines seriously from the perpendicular, and in spite of all the new stone used in refacing the exterior and in repairing the fissures, the body of the walls is still composed of the stone they were originally built of, and which has proved so untrustworthy. Nothing but rebuilding the tower entirely could have got rid of this.

I claim that we have, by the great work of restoration, rendered the tower absolutely secure, and, if fairly dealt with, able to stand for centuries to come in all its recovered beauty. Our pledge did not go beyond this, and I cannot but think that the past history of the tower affords a warning against exposing it once more to a strain which it is not designed to withstand.—Believe me, yours very faithfully,

J. OLDRID SCOTT, F.S.A.

31 Spring Gardens: Oct. 22, 1888.

A discussion followed, when it was agreed that the question of hanging the bells should be submitted to a body of referees, and that information was to be first obtained as to whether a committee of architects would consent to become referees, and as to whether it would be desirable and possible to associate with them, or to obtain independently, the opinion of an engineer or engineers, and at what cost the opinions could be obtained; the sub-committee to report the result of their inquiries at a future meeting.

### THE EDINBURGH GUILDRY.

ON Monday the annual meeting of the Edinburgh Guildry was held in the Council Chamber. Bailie Russell presided, and moved the re-election as Dean of Guild of Sir James Gowans. Sir James had had a great deal to do with the improvement of the city. His tact and ability and professional training had all been very marked, and had been of the greatest service to the city. The motion was unanimously adopted.

Sir James Gowans, who then took the chair, thanked the meeting for the honour they had done him in re-electing him for another year as Dean of Guild. He had great pleasure in the work of the Guildry Court. It went to his heart, it was quite in his way, and he was bound to say he would not have been in such good health if it had not been for the work of the Dean of Guild Court. He then gave a report of the work during the past year. The members of the Court, he said, took the opportunity of expressing their appreciation of the support and friendly co-operation which has been so readily given by the architectural profession and the leading master builders of the city. In connection with tenements of flatted houses, the Court had been at great pains to improve upon the old arrangements of dark, precipitous, and insanitary staircases. After careful consideration of the subject, for four-storey tenements the Court were of opinion that nothing less than a large roof-light or cupola over the staircase of an area of over 150 superficial feet, and an open "well" for light in the centre of the staircase of an area of 40 superficial feet, should be the minimum. The Court had also insisted on the heightening and thickening of the walls of chimneys, with a view to prevent smoky flues. Special attention had been given to new bakehouses. The practice had long been to utilise the basement or cellar flat of a tenement for bakehouses, where sufficient light and ventilation were impossible, and the heat and fumes were extremely liable to penetrate the occupied flats above. Parties had therefore been urged to arrange for having these erected above ground; and although the Court had not always been fully successful in this respect, still abundance of light and ventilation had been obtained in cases where they had been sanctioned, in addition to complete disconnection from the remainder of the tenement. In the beginning of the current year the Court prepared a pamphlet entitled "Memoranda for the Guidance of Petitioners, Architects, and Master Builders, with reference to the Preparation of Plans for the Dean of Guild Court and the Erection of New Houses and Buildings." This had not been taken advantage

of as it ought to have been, and they were still having complaints that they had not published a list of the requirements of the Court in the very particulars contained in the pamphlet referred to. Another important matter to which the Court had had its attention directed has been the disposition of parties to let and occupy new houses too soon. Of course, with modern appliances of steam cranes and mortar-grinding mills, houses were now erected more expeditiously than in former years, and the result was that the walls, plaster, and deafening retained moisture for a longer period after the houses were finished. It was, therefore, of vital importance that reasonable time be allowed for drying and seasoning, especially with houses and apartments where the light and heat of the sun did not directly operate. During the past year there had been 531 applications to the Court, as against 539 in 1886-7; 527 warrants were granted, as against 508; 163 had reference to first-class houses, villas, &c., as compared with 186; 125 had reference to tenements, as against 136; and there had been eleven prosecutions, as compared with 16 for 1886-87. The number of separate houses included in the statement for the year was:—Villas, 55; self-contained houses, 111; public buildings, public works, and business premises, 29; alterations on existing buildings, 403; 127 tenements, consisting of 148 shops and 1,229 houses—total number of dwelling-houses, 1,395. Of these 127 tenements, 14 had one apartment, 439 had two, 344 had three, 289 had four, 105 had six, 3 had seven, 1 had eight, 5 had nine, 2 had ten, and 1 had twelve. In 289 new buildings, drainage had been examined and tested, the extent of drains tested being 12¼ miles. The following houses and tenements had all the drains entirely outside the walls of the buildings:—Villas, 38; self-contained houses, 57; tenements, 62. The number of houses examined and certified by the burgh engineer and master of works as being fit for occupation in accordance with the Act was:—Self-contained houses, 63; villas, 27; public and other buildings, 14; 76 tenements, consisting of 112 shops and 711 houses—total number of houses, 801. The rental of the foregoing certified houses was as follows:—Houses of one and two apartments, yearly rental 5% to 13% inclusive, 275; houses of three apartments, yearly rental 14% to 18% inclusive, 124; houses of four apartments, yearly rental 19% to 29% inclusive, 194; houses of five or more apartments, and several self-contained houses, yearly rental 30% to 40% inclusive, 115; self-contained houses and villas, yearly rental 41% to 100% inclusive, 87; first-class villas, yearly rental 101% to 170% inclusive, 6. The total rental of the new houses certified during the year was 19,195%, and it was interesting to note that the increase of rental over that of the past year, as reported by Mr. Paterson, the city assessor, amounts to 28,375%, the following wards contributing to that sum as follows:—St. George's, 6,074%; Newington, 5,935%; St. Luke's, 3,194%; St. Cuthbert's, 3,047%. House accommodation of a most satisfactory and healthy description had thus been provided for an estimated population of 4,000 persons. The last extension of the city boundaries was made in 1882, over six years ago. That extension was evidently far too limited in its range, as already feuing had extended so as to certain points to touch, and even to stretch beyond, the city limits. Several fine healthy suburbs are being rapidly filled up, such as Craigmillar, Grange, Braid, and Plewlands. The acquisition of part of the Braid Hills as a public recreation ground would no doubt tend to develop feuing in that direction. Towards the west, the city was already touching the extended boundary at Gorgie, and feuing would no doubt stretch westwards still further. In the first-mentioned cases, such as Craigmillar, Grange, and Braid, and part of Plewlands, the feuing arrangements were such that each house possessed an extent of open ground far in excess of the minimum standard prescribed by the Act. But just in proportion as a city stretched her bounds, the more valuable became the ground towards the centre, as they are now having experience of in endeavouring to acquire a public park at Pitt Street. These facts showed the wisdom of securing ground for "lungs" and "recreation places" in time. Reference was made in last year's report to a movement which was then being inaugurated, viz., the registration of plumbers. This scheme was now in operation, and the result had been a healthy stimulus to the trade and the tradesmen, and improved workmanship. But it was worthy the earnest consideration of every one interested whether other tradesmen belonging especially to the building trades—such as masons, joiners, plasterers, &c.—should not adopt a similar registration scheme.

### BUILDING REGULATIONS IN GLASGOW.

AT the last sitting of the Glasgow Dean of Guild Court, Lord Dean of Guild Walls said:—Before entering upon the business of the Court this morning, I desire to draw attention to two or three questions of importance suggested by the fire which recently occurred in Buchanan Street. These valuable properties will no doubt be rebuilt, and it is the unanimous

opinion of the Court that in this, as in all cases in the city, the following suggestions ought to be rigidly followed out, the object, of course, being to use every means to prevent and limit the spread of fires. It is felt, therefore, first, that all foundations ought to be uniform in depth—that is to say, the foundation of a new building ought to be carried to the same depth as the old. This can easily be effected by either going deep enough with the new or under-building the old. Second, the walls of all buildings ought to be of a thickness and strength proportionate to the proposed height. Third, the height of all buildings, and especially of all warehouses intended for valuable combustible goods, ought to be uniform. Fourth, and what I consider most important, the utmost care ought to be exercised when joisting or any wood is necessarily brought contiguous to fireplaces or vents. Such timber ought to be bridled, and never carried nearer than a foot from vents or fireplaces. All hearths ought also to be placed on brick arches. I need scarcely say that these suggestions are thrown out alike in the interests of proprietors, tenants, and insurance offices, and if carefully carried out by architects and contractors much property, as well as many lives, may be saved. I cannot better illustrate the importance of what has been suggested on the subject of placing wood near fireplaces than to say that on the Monday following the great fire which took place in Buchanan Street, another fire originated in a large warehouse in Buchanan Street from this very cause. Fortunately it was detected in time, but had it occurred in the night it is impossible to say how disastrous it might have been. Other instances of a similar nature have recently come to my knowledge as having occurred in private houses from the same cause. I feel it to be my duty to add that the suggestions I have thrown out are entirely approved of by Mr. Paterson, chief of the fire brigade, and so far as is in the power of this Court they will be enforced.

#### FINE ART IN EDINBURGH UNIVERSITY.

ON Tuesday last Professor Baldwin Brown delivered the opening lecture of the session in his classroom of Edinburgh University. After sketching the main outlines of the session's course, which was to be on the general subject of Fine Arts in their origin, history, and relation to human life as a whole, the lecturer went on to deal briefly with the theme of the opening lecture, "Art as Decoration." This side of art was not so well understood and appreciated in the present day as in the past. When the ordinary person thought of a "work of art," he generally had before his mind one of the cabinet pictures or gallery pieces of sculpture familiar in exhibitions. But such were not to be looked on as typical forms of art. The cabinet picture was a comparatively modern invention. Both in painting and in sculpture the works of the finest periods of art in the past were of a decorative or monumental kind. Such, for example, were the frescoes of Giotto, Signorelli, Michel Angelo, and the sculptures of Pheidias. These works of decorative art differed from the pictures and statues of our exhibitions in their public character. The cabinet picture was the production of an individual artist, and was destined to pass into the private collection of some patron. Its interest was wholly in itself, it was independent and self-contained; while the monumental or decorative work appealed more largely to the public. This public character in decorative art led to healthful co-operation of many workers upon a single task, and as appealing to the ideas and beliefs current in a community, such decorative undertakings had a fulness of intellectual and moral interest often absent from works carried out in the modern spirit. The first point might be illustrated from the building and decoration of the great Mediaeval monuments, such as the Gothic cathedral or the churches and civic palaces of Italy. All grades of workmen toiled together upon the same social level, and opportunities were always being afforded for a man to rise to the higher branches of his art. The qualities of imagination and thought required for decorative work of the highest kind might be judged of by a reference to productions like the sculptured decoration of the Parthenon or the frescoes of Michel Angelo in the Sistine Chapel. With regard to these last, probably twenty people were familiar with the single figures for one who had entered into the spirit of the whole composition. The lecturer then illustrated Michel Angelo's scheme by a photograph and description of the Sistine vault, and concluded by urging the need for artists of education and attainments to turn their attention to the higher branches of decorative work. The national history and the ballad literature of Scotland would furnish motives in abundance, if any person or public body would come forward to give a commission, say for the adornment with mural paintings of the Parliament Hall in the Castle of Edinburgh. Now that there was no longer such a demand for cabinet pictures as there was ten years ago, there should be available a large amount of artistic talent for this great but neglected sphere of work.

"Antiquity after a time has the grace of novelty."—HAZLITT.

### HOW LORD ELGIN ACQUIRED THE PARTHENON SCULPTURE.

LORD BYRON, speaking as Minerva (see the "Curse of Minerva"), showered many curses upon the head of his brother peer, the Earl of Elgin, for carrying off the sculpture which is now in the British Museum. The diplomatist was a butt for the poet, and in "Childe Harold" he is said to be—

Cold as the crags upon his native coast,  
His mind as barren and his heart as hard.

Lord Byron explained the reasons which made him inimical towards the ambassador. "I am not," he said, "a collector or admirer of collections, consequently no rival; but I have some early prepossession in favour of Greece, and do not think the honour of England advanced by plunder, whether of India or Attica." But we imagine there was a still stronger reason. Lord Byron, as became a poet, was an admirer of nature; but in his famous letter on the Pope and Bowles controversy he maintained it was in a measure through the aid of art that nature became poetical. "Am I to be told," he asked, "that the 'nature' of Attica would be more poetical without the 'art' of the Acropolis? of the Temple of Theseus? and of the still all-Greek and glorious monuments of her exquisitely-artificial genius? Ask the traveller what strikes him as most poetical, the Parthenon or the rock on which it stands?" Owing to the acquisitiveness of Lord Elgin the Parthenon was mutilated; it was no longer able to exercise its old powers on poets, and therefore the culprit had committed one of the greatest of crimes. Such was Lord Byron's reasoning. He wrote as a poet who felt that a source of inspiration was lost.

There is no doubt that many people at the time felt that Lord Elgin's conduct was not praiseworthy. It was a time when England was very sensitive about acquiring any part of the property of another nation; and as Lord Elgin filled the office of ambassador his acts were supposed to compromise the country. Accordingly, when his lordship petitioned the House of Commons to purchase the marbles, his method of obtaining the works was declared by the House to be flagitious and dishonest. Afterwards a better spirit prevailed. The fact that the King of Bavaria lodged 30,000*l.* with a banker for the purpose of purchasing the sculpture could hardly fail to be without effect upon the Government of the time. A committee was appointed to inquire into the subject. Lord Elgin was examined, and, as will be seen from the evidence, was questioned in a manner which suggests the strength of the prejudice against his lordship. Finally, the sum of 35,000*l.* was voted as the value of the sculpture.

The Earl of ELGIN was called in and thus questioned:—

Your lordship will be pleased to state the circumstances under which you became possessed of this collection, and the authority which you received for taking the marbles from Athens?—The idea was suggested to me in the year 1799, at the period of my nomination to the Embassy at Constantinople, by Mr. Harrison, an architect, who was working for me in Scotland, and who had passed the greater part of his life in Rome, and his observation was that, though the public was in possession of everything to give them a general knowledge of the remains of Athens, yet they had nothing to convey to artists, particularly to students, that which the actual representation by cast would more effectually give them. Upon that suggestion, I communicated very fully with my acquaintances in London. I mentioned it to Lord Grenville, Mr. Pitt, and Mr. Dundas, upon the idea that it was of such national importance that the Government might be induced to take it up, not only to obtain the object, but also to obtain it by the means of the most able artists at that time in England. The answer of Government, which was entirely negative, was that the Government would not have been justified in undertaking any expense of an indefinite nature, particularly under the little probability that then existed of the success of the undertaking. Upon that understanding I applied to such artists here as were recommended to me as likely to answer the purpose, in particular to Mr. Turner, to go upon my own account. Mr. Turner's objection to my plan was that, as the object was of a general nature, and that the condition I insisted upon was that the whole results of all the artists should be collected together and left with me, he objected because he wished to retain a certain portion of his own labour for his own use; he moreover asked between seven and eight hundred pounds of salary, independently of his expenses being paid, which of course was out of my reach altogether; therefore nothing was done here preparatory to the undertaking at all. When I went to Sicily

I met Sir William Hamilton, to whom I explained my views; he encouraged my idea, and applied to the King of Naples for permission for me to engage his painter Lusieri, who was at that time employed in picturesque views of Sicily for the Sicilian Government; who went with Mr. Hamilton to Rome, and, upon the plan arranged with Sir William Hamilton, engaged the five other artists who accompanied him ultimately to Turkey. Those five persons were two architects, two modellers, and one figure painter. Lusieri was a general painter. They reached Constantinople about the middle of May 1800, at the time when the French were in full possession of Egypt, and of course no attempts could be made with any prospect of general success. I sent them to Athens, however, as soon as an opportunity offered: for several months they had no access to the Acropolis, except for the purpose of drawing, and that at an expense of five guineas a day; that lasted from August 1800 till the month of April 1801.

That limited access lasted about nine months?—Yes.

The fee of five guineas was one usually demanded from strangers?—There were so few strangers there I do not know, but in the instances which came to my knowledge it was so. During that period my artists were employed in the buildings in the low town of Athens. In proportion with the change of affairs in our relations towards Turkey, the facilities of access were increased to me and to all English travellers; and about the middle of the summer of 1801 all difficulties were removed. We then had access for general purposes. The same facilities continued till my departure from Turkey in January 1803, at which period I withdrew five out of the six artists; and having sent home everything that was in the collection, till the year 1812 Lusieri remained, with such instructions, and such means, and such powers, as enabled him to carry on the same operation to the extent that then remained to make it, as I concluded, more perfect: but from that period of 1803 till the present day, during my imprisonment in France, and during the remaining years, he has acted without any interruption, in the enjoyment of the same facilities, with a renewal of the same authorities; he has incurred the same expenses and done the same as before.

Where is he now?—Remaining there still; he was not there during the war, but he has obtained a renewal of the same authorities since.

Your lordship has stated that when the change took place in the political relations between this country and Turkey a facility of access was continued to you and all your artists?—Yes.

And in 1801 all difficulties were removed which applied to the erecting scaffolding and making excavations; was the same permission to erect scaffolding and make excavations given to other persons at Athens at that time?—I do not know of any such instance; other persons made use of the same scaffolding of course. I do not know that any specific permission of this kind was applied for; I believe the permission granted to me was the same in substance and in purport as to any other person, with the difference of the extent of means and an unlimited use of money. There was nobody there, I believe, who was doing anything but draw.

Did the permission specifically refer to removing statues, or was that left to discretion?—No; it was executed by the means of those general permissions granted; in point of fact, permission issuing from the Porte for any of the distant provinces is little better than an authority to make the best bargain you can with the local authorities. The permission was to draw, model, and remove; there was a specific permission to excavate in a particular place.

Was the permission in writing?—It was, and addressed by the Porte to the local authorities, to whom I delivered it; and I have retained none of them. In a letter I addressed to Mr. Long in the year 1811 I made use of these words:—"That the ministers of the Porte were prevailed upon, after much trouble and patient solicitation, to grant me an authority to remove what I might discover, as well as draw and model."

Does your lordship suppose this to have been the same form of permission that had been given to other people; and that your lordship employed it to a greater extent than other people?—It was so far different that no other person had applied for permission to remove or model.

Does your lordship know whether any permission had been granted to any other person to remove or model?—Monsieur de Choiseul had the same permission; and some of the things he removed are now in my collection.

He removed them while he was minister at the Porte?—Yes.

Had that permission ever been granted to excavate and remove before Monsieur Choiseul had it?—I do not know.

There seems to be a considerable difference between to excavate and remove and to remove and excavate; the question was not whether your lordship was permitted to remove what you should find on excavation, but whether your lordship was permitted to remove from the walls?—I was at liberty

to remove from the walls; the permission was to remove generally.

Was there any specific permission alluding to the statues particularly?—I do not know whether it specified the statues, or whether it was a general power to remove. I was obliged to send from Athens to Constantinople for permission to remove a house.

That was a house belonging to the Turkish Government; did not your lordship keep any copy of any of the written permissions that were given to your lordship?—I kept no copies whatever; every paper that could be of use at Athens was left there as a matter of course, because Lusieri continued there: the few papers I brought away with me were burnt on my detention in France; my private papers I mean, and all my accounts, which I had brought away from Turkey.

In point of fact, your lordship has not in England any copy of any of those written permissions?—None.

Did the committee understand you to say that it is possible Lusieri has such copies?—Certainly; they will be at Athens, either in his possession or in the possession of the authorities there.

Has your lordship any distinct recollection of having had such copies of the authorities, and of having left them in Lusieri's possession?—I cannot speak to the fact so precisely as the committee may wish; the authority itself was given over to the proper officer, and then Lusieri obtained from him any part of it that was necessary to be exhibited on any future occasion.

Did your lordship, for your own satisfaction, keep any copy of the terms of those permissions?—No, I never did; and it never occurred to me that the question would arise; the thing was done publicly before the whole world. I employed three or four hundred people a day; and all the local authorities were concerned in it, as well as the Turkish Government.

When your lordship stated that the permission granted to your lordship was the same that had been granted to other individuals, with the difference only of the extent of means, did you mean to convey to the committee that permissions to remove marbles and carry them away had been granted to other individuals?—No; what I meant to say was this, that as far as any application was made to the Turkish Government through me, or to my knowledge, the same facilities were granted in all cases. I did not receive more as ambassador than they received as travellers; but as I employed artists, those permissions were added to my leave. I am not aware of any particular application being made for a specific leave that was not granted where a similar leave was granted to myself.

Your lordship has stated that no individual had applied for leave to remove?—To the best of my recollection no application had been made to remove.

No application, either through you or to your knowledge?—Yes; as far as I can recollect.

Of course your lordship means to except the permission that you stated before had been long antecedently given to Monsieur Comte de Choiseul?—Yes.

Do you know, in point of fact, whether the same permission was granted to Monsieur Comte de Choiseul as was granted to you?—He exercised the same power.

But you do not know whether he had the same permission?—No.

Then within your lordship's knowledge there is no instance of a private individual having obtained such permission?—I have no knowledge of any individual having applied for it, and I do not know whether it has been granted or not; I do not know that there was any difficulty in the way of removing by anybody.

Was it necessary that those powers should be renewed after your lordship came away, and that the artists already employed by you are employed ostensibly by the ministers there?—I do not know what distinction there is between Lusieri and any other artist.

Is he acting under the permission your lordship obtained?—There has been war since.

Has it been renewed to your lordship, or individually to themselves?—They have made the application through the channel they thought proper; what it was I do not know; but it was probably the same permission that Lord Aberdeen had, and many other travellers that have been there.

Your lordship does not know whether it was renewed to your lordship or to Mr. Liston, or whether they are acting under a permission granted to him, or individual permissions granted to the artists?—I do not know what the detail is; I conclude they are acting exactly as any other traveller there is: there is no advantage from the ambassadorial title that I had then that can apply to them now, because there has been war since.

Have they power to excavate, model, and remove?—They have removed a great deal from thence.

And you do not know in what shape those powers have been renewed since the war?—No, I do not.

In the letter to Mr. Long, which you have stated, you speak as having obtained these permissions after much trouble and patient solicitation; what was the nature of the objections on the part of the Turkish Government?—Their general jealousy and enmity to every Christian of every denomination, and every interference on their part. I believe that from the period of the reign of Louis XIV. the French Government have been endeavouring to obtain similar advantages, and particularly the Sigean marble.

They rested it upon that general objection?—Upon the general enmity to what they called Christian dogs.

That was not the manner in which they stated their objection?—No, but that is the fact; it was always refused.

Without reasons?—Without reasons assigned; everybody on the spot knew what those reasons were, that they would not give any facility to anything that was not Turkish.

All your lordship's communications with the Porte were verbal?—There was nothing in writing till an order was issued.

The objection disappeared from the moment of the decided success of our arms in Egypt?—Yes; the whole system of Turkish feeling met with a revolution, in the first place, from the invasion by the French, and afterwards by our conquest.

Your lordship has stated in your petition that you directed your attention in an especial manner to the benefit of rescuing from danger the remains of sculpture and architecture; what steps did you take for that purpose?—My whole plan was to measure and to draw everything that remained and could be traced of architecture, to model the peculiar features of architecture. I brought home a piece of each description of column, for instance, and capitals and decorations of every description, friezes and moulds, and, in some instances, original specimens; and the architects not only went over the measurements that had been before traced, but by removing the foundations were enabled to extend them and to open the way to further inquiries, which have been attended since with considerable success.

You state that you have rescued the remains from danger?—From the period of Stuart's visit to Athens till the time I went to Turkey a very great destruction had taken place. There was an old temple on the Ilissus had disappeared. There was in the neighbourhood of Elis and Olympia another temple, which had disappeared. At Corinth I think Stuart gives thirteen columns, and there were only five when I got there; every traveller coming added to the general defacement of the statuary in his reach: there are now in London pieces broken off within our day. And the Turks have been continually defacing the heads; and in some instances they have actually acknowledged to me that they have pounded down the statues to convert them into mortar. It was upon these suggestions and with these feelings that I proceeded to remove as much of the sculpture as I conveniently could; it was no part of my original plan to bring away anything but my models.

Then your lordship did not do anything to rescue them in any other way than to bring away such as you found?—No, it was impossible for me to do more than that; the Turkish Government attached no importance to them in the world; and in all the modern walls these things are built up promiscuously with common stones.

It has been stated that in a despatch from Turkey, at a very early period after your lordship went out, that your lordship had an occasion to write to His Majesty's Government concerning your public appointment as a minister, and that you stated some circumstances distinctly to them at that time which showed your understanding, and their understanding, that your proceedings in Greece were entirely upon your own private account; is that statement correct that there is a document in existence, dated in the year 1803, which will prove that fact?—There is, precisely what is alluded to in a despatch at the period of my leaving Turkey.

In point of fact, did the Turkish Government know that your lordship was removing these statues under the permission your lordship had obtained from them?—No doubt was ever expressed to me of their knowledge of it; and as the operation has been going on these seventeen years without any such expression, so far as I have ever heard, I conclude they must have been in the intimate knowledge of everything that was doing.

In point of fact, your lordship does not know that they were ever apprised of it?—It is impossible for me to have any doubt about it.

Did your lordship ever apprise any of the Government of it in conversation?—The chance is that I have done it five hundred times, but I cannot answer specifically when or how.

Did not the committee understand your lordship to say that they must have so well understood it that in one instance your lordship got a special order to remove a particular thing?—There was a special permission solicited for the house; when I did excavate in consequence of getting possession of that house there was not a single fragment found; I excavated down to the rock, and that without finding anything, when the Turk to whom the house belonged came to me and laughingly told me

that they were made into the mortar with which he built his house.

Then the permission was to buy the house?—To pull it down.

Since 1803 has Lusieri continued to remove things?—I can answer that question by a fact of considerable importance. When I was in Paris a prisoner, in the year 1805, living in Paris perfectly tranquilly with my family, I received a letter from an English traveller complaining of Lusieri's taking down part of the frieze of the Parthenon. The next morning a common gendarme came and took me out of bed, and sent me into close confinement away from my family. Such was the influence exercised by the French to prevent this operation.

Your lordship attributed it entirely to the French?—Yes; the French sent me in that way down to Melun.

In reference to what was stated in a passage of your lordship's petition, will your lordship be so good as to say whether you have ever heard of the Turkish Government taking any care that the works of art should not be destroyed?—Certainly not; within my knowledge nothing of the sort was ever done; the military Governor of the Acropolis endeavoured to keep them after people had appeared anxious to get them away.

So that the hesitation on the part of the Government your lordship attributes to a dislike to the Christians?—The general apprehension of doing any act displeasing to the French operated at the time the French were in Egypt.

Has your lordship any knowledge of any particular application made to the Turkish Government by any individual, and granted, of an equal extent with your lordship's?—I have not any knowledge of what has passed since, except the details of Lusieri's own operations.

From an observation in part of your lordship's evidence, the committee concluded that your lordship has, since 1812, received several of these marbles?—In the year 1812 about eighty cases arrived.

Have there been any received subsequently?—I believe there have, but I am not very certain, having been out of the country myself.

(To be continued.)

## SCHOOL BUILDINGS.

**Birmingham.**—The latest addition to the buildings of the Birmingham School Board, the commodious schools which have been erected in the Soho Road, near to the Soho Station on the Great Western Railway, were open lately for educational work. All the other existing schools of the Board have been erected from designs by Messrs. Martin & Chamberlain, but in this case an exception to the previous rule has been made. In 1886 five invitations were sent to selected Birmingham architects to send in designs for school buildings on the Soho site, which were to be arranged on the central hall principle, and to be of one storey in height. One of the five sets of designs was, after careful consideration, unanimously selected by the Sites and Buildings Committee, and subsequently approved by the Board, and this design, which it subsequently transpired was by Messrs. Thomason & Whitwell, has now, after considerable delay, been carried out. The site, though considered to be the best obtainable in the neighbourhood, was extremely uneven and depressed below the level of the road. The lower parts have required to be filled up to a considerable depth, and as it proved that the land had been deeply excavated for clay, and that but little of it was solid ground, a very heavy outlay was occasioned in the foundations, retaining walls, brick arching to carry paved floors, &c. Sixteen classrooms are provided, each to accommodate sixty scholars. Eight of these are arranged in pairs divided by revolving screens. The classrooms are grouped around two large assembly halls, the first of which measures 67 feet by 30 feet, and the second, for the junior half of the school, 55 feet by 30 feet. Five spacious entrances, which serve as cloak-rooms, give easy access to the playgrounds. Three private rooms are provided for the teachers. All the parts are in easy communication, and the whole is arranged so as to give every possible facility for inspection and control. The rooms and corridors are well lighted throughout, and the aspect internally and externally is rendered pleasing and cheerful without resort to expensive ornament. The exterior architecture is of a distinctive character. It is Gothic in feeling and expression, but does not closely follow any particular phase or period of that style. The material of the external walls is brick, with terra-cotta, principally of buff colour, moderately used in the windows and doorways. The central windows in the classroom gables are of very large size, mostly three lights in width, with terra-cotta mullions and transoms, behind which are wood frames to contain the glazing, designed so as to give the greatest possible lighting space. The ventilating turret is of simple outline, and terminates in a slated spire. The caretaker's house adjoins the entrance to the girls' department from Soho Road, and has

dressings of buff terra-cotta to the windows, varying in design from those in the schools proper. The terra-cotta used was made by Messrs. Joseph King & Co., of Stourbridge. Messrs. Wilson & Son, of Soho Hill, are the builders. The school desks and other furniture are the work of Messrs. David Clark & Co. and of Messrs. Bernard Clarke & Sons. As already stated, Messrs. Yeoville Thomason & Cooper Whitwell, of Cannon Street, Birmingham, were the architects; and Mr. J. Chattaway, the clerk of the works to the School Board, acted under them in superintending the erection of the buildings. The builders' contract amounted to 8,900*l.*, but to this sum considerable extra cost has to be added for the extension of the playgrounds and for additional work necessitated in making the foundations.

### GENERAL.

**Mr. J. F. White, LL.D.**, has presented to the Aberdeen Art Gallery Committee a landscape picture, *The Water Lilies*, by W. Roelofs, the Dutch painter.

**Mr. Crozier, C.E.**, county architect of Durham, has sent in his resignation, after fulfilling the duties of that office for about forty years.

**Messrs. Paley & Austin** have prepared plans for the erection of the proposed new church, St. John's, Cloughfold, Rawtenstall.

**Mr. H. Ross Hooper** will read a paper on "The Practice of Foundry Work" at the meeting of the Society of Engineers on Monday evening, the 5th inst.

**Mr. James Ormrod**, of Halliwell Lodge, Bolton, is erecting at his own cost a church in the neighbourhood of his Welsh seat, near Ruabon.

**The Prince of Wales** has engaged to open the Jubilee Memorial Hall at Ealing about the middle of this month.

**Lady Whitworth** and her co-executors are giving to Darley Dale, Derbyshire, under the will of the late Sir Joseph Whitworth, an institute for educational and recreative purposes, a hospital, and a smaller hospital for infectious diseases. The total expenditure is estimated at upwards of 25,000*l.*

**The Council of the Sanitary Institute**, at a meeting held on October 25, enrolled thirty-eight members and Associates.

**The Public Buildings** erected at Darlaston from the designs of Mr. J. A. Cossins, of Birmingham, as a Jubilee memorial, were formally opened on Wednesday.

**The Town Hall**, which has been erected at Burnley at a cost of 40,000*l.*, was formally opened on Saturday.

**The Bridge House Estates Committee** purpose obtaining parliamentary powers for an extension of four years' time for completing the Tower Bridge.

**The Gordon Institute** for working lads was opened at Liverpool on Saturday by the Earl of Meath.

**The Jubilee Nursing Institute**, erected from the designs of Mr. J. Houghton Spencer, at Taunton, at a cost of 10,000*l.*, has been opened by the Hon. W. H. B. Portman. Among the subscribers was an anonymous donor, who gave 5,000*l.*

**The Plans** of the Roman Catholic church, which is to be erected at St. Anne's-on-the-Sea, at an outlay of 12,000*l.*, have been prepared by Messrs. Pugin & Pugin, of Westminster.

**Derby House**, in Watergate Street, Chester, known as the ancient palace of the Stanleys, has been purchased from the Chester Archaeological Society by Lord Derby, who intends to preserve the building as an archaeological and historic relic.

**An Executive Committee**, of which the Mayor is the chairman, has been appointed to raise 5,000*l.* as an expenses and guarantee fund, for the visit of the British Association to Leeds in 1890.

**A Conservative Club**, erected from the designs of Messrs. Pierpoint & Fraser, of Warrington, in Elizabethan style, has been opened by Lord Cranborne at Widnes.

**A Faculty** has been granted for the addition of a south aisle to All Saints' Church, Edmonton, according to the designs of Mr. Scott. A sum of 1,900*l.* is also to be spent in alterations at South Hackney parish church.

**A Professorship of Architecture** is proposed to be established for the province of Ontario, Canada.

**Lord Egerton of Tatton** has promised 500*l.*, and Mr. Samuel Hargreaves 1,000*l.*, towards the cost of the restoration of the chancel and other parts of St. Wilfrid's Church, Mobberley, Knutsford.

**A Bazaar** in aid of the building fund for a manse at the Presbyterian church in Dunfermline is open in the Drill Hall, which is arranged to represent a street in Jerusalem.

**Burton Dassett Church**, Warwickshire, has undergone partial restoration under the direction of Mr. J. A. Cossins, of Birmingham.

**The Brighton Alhambra**, built from the designs of Mr. Frank Matcham, as a music-hall, was opened with a performance on Monday night. The building has been constructed so that, if required, it can be converted to the purposes of a circus.

**The Glasgow Town Council** on Monday gave approval to a scheme for building a public hall at Camlachie, and granted a site for the purpose at a nominal rent of one shilling per annum.

**The Foundation-stone** of a Conservative club at Watford, which is being erected from the designs of Mr. W. H. Syme, A.R.I.B.A., has been laid.

**The Conversazione** of the Edinburgh Architectural Association was held on Thursday evening, when Professor G. Baldwin Brown, M.A., the president, delivered an address, his subject being "Some Aspects of the Work of an Architectural Association."

**H.R.H. the Prince of Wales** has consented to visit Middlesbrough in January for the purpose of opening the new town hall and municipal buildings, Middlesbrough, which have been erected from the designs of Mr. G. Gordon Hoskins, F.R.I.B.A., at an estimated cost of 120,000*l.*

**A Church** is to be built at Seascale, at a cost of about 2,000*l.*, from the designs of Mr. C. J. Ferguson, of Carlisle.

**A Surplus of £90** has been realised from the Art and Industrial Exhibition lately held in Penrith.

**The Church** built by Lord Northbrook on his estate, at Stratton, was opened on Thursday.

**The Winter Garden** at Cheltenham is being utilised for a ten days' bazaar. The building has been formed into an Oriental city, with gate of the Palace of Aladdin, streets of palaces, an imitation of the Alhambra with its court of lions, the Bridge of the Golden Pactolus, and a sky of Eastern blue.

**A Bazaar** has been opened in the town hall of Atherstone in aid of the restoration fund of the parish church chancel.

**A Building**, to comprise a public hall and recreation-rooms, is proposed to be erected at Newtown St. Boswells, as a memorial of the late Hon. Major Baillie, of Dryburgh.

**Mr. Alexander Duncan**, of Rhode Island, U.S., has offered to give 1,000*l.* to the directors of the Arbroath Infirmary, for the purpose of building a convalescent house for that institution.

**The Heritors of St. Cuthbert's Parish, Edinburgh**, have approved of plans for reseating and alterations in the church, which will cost 10,000*l.* to carry out.

**The Society of Architects** will have a conversazione at the New Gallery, Regent Street, on the 13th inst., when the President will deliver an address. A special general meeting will be held in St. James's Hall on the 27th inst.

**Mr. C. Gourlay, Architect**, has commenced a course of lectures on "Hygiene for Architects and Builders," in connection with the Glasgow and West of Scotland Technical College.

**The Portuguese Government** are inviting tenders of designs for the building of a Palais de Justice for the accommodation of all the Courts of Justice in that capital, with the exception of the Commercial Court. Further particulars may be learned on personal application to the Commercial Department of the Foreign Office.

**Mr. Mark H. Judge**, architect, is a candidate for a seat on the London County Council for North Paddington.

**Operations** for widening Irvine Bridge have been started. The first mention of an Irvine Bridge was in a document bearing the date of 1533. On August 8 of that year Hugh, first Earl of Eglinton, was appointed by Patrick, Earl of Bothwell, Great Admiral of Scotland, to be Depute-Admiral within the bounds of Cunninghame—"This is to say, betwix Kelly burn and the brig of Irwyn." The brig of 1533 was probably the "faire stone brydge" mentioned by old Timothy Pont in 1608. The contract for the rebuilding of the old portion of the present structure is dated 1748. It was only 11 feet wide, and in 1826 that width was doubled from plans by the late Mr. Paterson, of the Union Bank here. The present widening will throw the whole space between the parapets into the roadway, and give broad pavements besides. There are three arches, and the river is at this part about 70 yards broad.

**CRIMINAL PROCEEDINGS**, under the new Merchandise Act, will be instituted against any person falsely representing any form of ventilator to be a Self-acting Air-pump Ventilator, said title being registered and our Trade-Mark, applicable only to ventilators manufactured by us. Any infringement renders the person infringing liable to two years' imprisonment. ROBERT BOYLE & SON, LD.

A. H. Steele, Dover . . . . .	2,625	0	0

For Improvement Works, Odo Road and Widred Road, including Surface Drains, &c., catchpits and tarred footways. Plans and Specifications by Mr. W. THOMAS, Borough Surveyor.

A. H. Steel, Dover . . . . .	£245	0	0
W. Bromley, Dover . . . . .	200	0	0
W. T. DOWLE, jun., Dover (accepted) . . . . .	145	0	0

# IMPROVED FLAT BRICK FIRE-PROOF FLOORS.

No. 1.—Longitudinal Section.

No. 2.—Longitudinal Section.

## NO THRUST ON WALLS.

The BEST as well as the CHEAPEST Fire-proof Floors yet introduced.

THEY are constructed with purpose-made hard-burnt bricks, with specially moulded dovetail projections, forming a mechanical key to hold the plaster protecting the iron, and provided with wedge joints throughout, forming the most compact and solid floor known. Experiments show a resistance to load and impact greater than furnished by the ordinary concrete floors. No thrust is transmitted to the walls, as in all arched construction, the walls being tied in and strengthened.

The floors are practically noiseless, the different densities of the concrete, brick and plaster, with the air space above, intercepting the sound vibrations.

The depth of the finished floor is 6 to 9 inches only, and when the saving on this head is taken into account, the cost does not exceed that of the ordinary combustible timber floor of corresponding strength.

# HOMAN & RODGERS,

**TRADE NOTES.**

It is proposed to form a company for the construction of swimming baths and steam laundries at Inverness.

THE Sheffield Chambers of Commerce will meet on Tuesday next to receive a report by Mr. Abernethy, C.E., and Mr. C. Hawkesley, C.E., who were appointed to survey the route of the proposed ship canal from Sheffield to the Humber.

A SCHEME has been drawn up by Mr. J. T. Woodhouse, of Hull, for the administration of the 50,000l. given to the borough for educational purposes by Mr. Robert Hymers. After providing for site and buildings, it is estimated that there will be 30,000l. available as an endowment.

EXCAVATIONS in the nave of St. Michael's Church, Millbrook, which was restored over thirty years ago by the Duke of Bedford, have been made to form a heating chamber, with the result that one of the nave pillars and arches has collapsed. No architect apparently was called in to superintend the work.

ON Saturday, at the meeting of the Skipton Rural Sanitary Authority, in connection with the Barnoldswick water supply, it was resolved that boring operations be renewed in accordance with Mr. De Rance's recommendations. Tenders for the work are to be obtained for submission at the next meeting.

A BRIDGE in course of erection at Appleby, Westmoreland, was washed down on Sunday afternoon. The Eden was at high flood, and the newly-erected arches with the wooden centres fell with a crash into the flood.

THE Caputh Bridge over the Tay, in presence of Mr. Arrol and Mr. Tylis as representatives of the contractors, was satisfactorily tested for traffic on Friday.

EFFORTS are being made to improve the electric-lighting system in Leamington, and it is expected that three new methods of using the light for purposes of street illumination will be before the public by the end of next week.

A LOCAL Government inquiry will open at Pontefract next Wednesday, to consider the application of the Town Council for sanction to borrow 23,152l. for works of water supply.

A GANG of men engaged in cleaning the flues of the blas furnaces at Cyfarthfa Ironworks, near Merthyr, on Sunday were overcome by the vapours, causing the death of three men the lives of five others being despaired of.

THE Infectious Diseases Hospital, Northfield, is warmed and ventilated by means of Shorland's patent Manchester grates, supplied by Mr. E. H. Shorland, of Manchester and London.

ON November 8 another penny journal will make its first appearance. *Information*, as the new comer is entitled, appeals to "all classes" for their support, and in return promises information on all subjects. With illustrated articles on "Royal Residences" and on "Early English Newspapers," copious notes on scientific and other facts, current musical and dramatic events, an able chess column, &c. &c., it seems well worth buying; and if the subsequent numbers keep up the high standard of the advance copy the new venture will obtain a large circulation.

ALTERATIONS have been made at the Guildhall, Worcester,

SOMETHING NEW

AND EFFECTIVE.

embracing the ventilation, Messrs. Robert Boyle & Son's latest improved patent self-acting air-pump ventilators being adopted for the extraction of the vitiated air.

A HANDSOME and massive eagle lectern has just been presented to Ranmoor Church, Sheffield. It is entirely of polished brass, with a richly chased foliated capital and twisted shaft, supported by three lions at the base. The work has been carried out by Messrs. Hardman, Powell & Co., of Birmingham.

MESSRS. AIRD'S tender has been accepted for the Contract No. 6 of the new Manchester Waterworks. It amounts to 163,745*l.* 6*s.* 9*d.* Messrs. Knight & Co. have obtained the contract for the construction of the Prestwich reservoir, amounting to 23,297*l.*

SWIMMING BATHS are proposed to be constructed at Dorking, and a company is to be formed to obtain the funds for carrying out the work. Mr. F. J. Dibble has been appointed architect.

THE quarterly return of expenditure by the Liverpool Water Committee for the three months ending September 30, shows that 45,725*l.* 10*s.* 3*d.* has been expended in connection with the Vyrnwy works. This amount is made up as follows:—Llanwddyn embankment works and works in connection with the reservoir, 9,685*l.* 10*s.* 1*d.*; Llanwddyn quarry, 2,022*l.* 17*s.* 7*d.*; aqueduct, 29,373*l.* 18*s.* 1*d.*; land and easements, 3,257*l.* 7*s.* 8*d.*; and maintenance of the Vyrnwy estate, 1,373*l.* 16*s.* 10*d.* The total expenditure since the commencement of the works is 1,812,375*l.* 18*s.* 5*d.*

MESSRS. WRIGHT SUTCLIFFE & SON have issued a handy little book, with instructions how to fix their "National" chimney pot and "National chimney top" smoke cure, with also a valuable reprint of the testimonials received by the firm.

THE arbitration as to the amount to be paid to Captain Park Yates by the Manchester Ship Canal Company for land at Ince and Thornton required by the company concluded on Tuesday. The landowner claims upwards of 73,000*l.*, but the company contend that 26,000*l.* will be fair remuneration. The umpire, Mr. Beadel, M.P., will give his award without delay.

IT is proposed to place a stained-glass window in St. Leonard's parish church, Middleton, in memory of the late rector, the Rev. Waldegrave Brewster.

WAR OFFICE authorities contemplate a considerable extension of Warley Barracks, and the creation of a military

centre for the Eastern counties. It is rumoured that the intention is to form headquarters for an Army Corps, and to build extra barrack accommodation for five thousand men.

AN important addition has just been made to the Aberdeen Waterworks, in the two large reservoirs which have been constructed at Mannofield and Slopefield. The water storage of the town will be thus increased by thirteen million gallons. The Mannofield reservoir is 20 feet in depth and 370 feet in diameter, and is capable of containing twelve million gallons of water. The walls of the reservoir are built of granite, the bottom being filled in with concrete. The total cost has been 21,211*l.* The Slopefield reservoir, which is 270 feet in diameter and 18 feet 8 inches in depth, has storage capacity of six million gallons. The cost, including ground, has been 11,053*l.*

AT the meeting of the Works Committee of the Dundee Police Commission it was reported that Messrs. Young & Co., Glasgow, the contractors for the Fairmuir Railway extension, had come upon a large amount of rock, and that an arrangement had been made with them to bring this rock to Ninewells and construct the embankment from that point to the foot of Windsor Street, Mr. Will, the present contractor, having given up that part of his contract on consideration that he should build a parapet wall along the whole length of the embankment. The committee approved of this arrangement, by which they expect to save a considerable sum of money.

#### PRESTON PARISH CHURCH, &c.

A MEETING of seatholders was held in the vestry on Thursday of last week "to consider how best to meet the heavy extra expenses which have been incurred in the recent cleaning and renovation of the church and in effecting improvements consequent on the removal of the organ." Mr. T. Harrison Myres, architect, asked permission to make some remarks. He said: I have felt it my duty to attend this meeting to-night in response to the notice duly received, and while I hope earnestly there will be a liberal and satisfactory amount of the needful raised, I ask to be allowed to lay before you a few facts, mainly in connection with a course lately adopted by the cleaning committee. I was not aware that it was the intention of anyone in power to include in any contract such works as have been carried out until I happened to see an account—mild in its form—in a local paper of a protest against

# "EMPRESS" SMOKE CURE.

EWART & SON,  
346 EUSTON ROAD,  
LONDON, N.W.

such. It has for some time been a parochial, nay, I may say a national, cry that the beautiful Bath stone arcade of the nave of our mother church should have received a coating of wash, to make it harmonise with the plaster walls. I call this vandalism in its true sense. I have not the pleasure of knowing any of the cleaning committee, but I should heartily have liked to have seen them whitewashed. Surely, the churchwardens and sidesmen ought not to have allowed such disfigurement to be done in this sacred building. Rather I take it to be their office to protect the fabric, and prevent any contractor spoiling the interior. My wrath at this destructive work has been intense. Let me read you a letter I have received upon this subject from one who has had great experience—a diocesan surveyor of Staffordshire, and an architect of some repute. "Stoke-upon-Trent.—My dear Myres,—When last in Preston you very kindly took me to see your fine parish church, which struck me as being well worthy of artistic respect in every way. It is a matter of regret to me to hear that the natural face of the stonework to the nave arcades has been tampered with in a way to destroy the pleasant variety of stonework in contrast to plaster facing. One does not like to be harsh in respect of the judgment of others, but this proceeding does appear to be of very questionable taste.—Yours sincerely, CHARLES LYNAM, F.R.I.B.A." I have also received another long letter of protest from the Hon. Corresponding Secretary of the Society for the Protection of Ancient Buildings, but the writer wished the contents to be regarded as private. I will just read you one or two extracts issued by the Royal Institute of British Architects:—"Hints to workmen engaged in the repairs and restoration of buildings. If directed to clean off whitewash or paint from internal or other stonework, recollect that the object of so doing is to bring to view the original surface, not to destroy it. You must, therefore, avoid the use of the tool, and study what is the best way of removing the whitewash without in any degree disturbing, much less removing, the ancient surface." You see, therefore, Mr. Chairman, we shall have great difficulty now in taking off that which has so indiscreetly been placed upon these stones by the cleaning committee. I would, therefore, suggest before money is asked for, that the whole of the colour wash be taken from the nave arcades, including the pillars, caps, and arches, at the expense of the wise committee, and then appeal to the seatholders. I should have thought that the refusal of the lay rector to allow the chancel to be touched would have given the keynote for the nave not to be touched also. Let "protection"

for the future be our motto in place of restoration or destruction. It is to prevent further desecration of this and other buildings that I have thus spoken out, but I assure you, Mr. Chairman, I must and will on all occasions speak plainly upon such a subject as the one before us. It was afterwards resolved that a voluntary rate equal in value to each sitting be laid, to be paid before Christmas. Votes of thanks to the wardens for their services and to the vicar for presiding were next accorded, and the meeting then closed.

#### LIVERPOOL THEATRES.

A SPECIAL session of the magistrates of the city of Liverpool was held in the Police Court, Dale Street, on Friday, for the purpose of considering applications for theatrical licenses for the performance of stage plays. Sir James Picton presided, and the other justices present were Admiral Gough, C.B., Dr. Costine, Alderman Samuelson, and Mr. G. Behrend. On the magistrates taking their seats, the chairman said he would, before they began business, say a word or two as to what had been previously done. They were all aware that public attention had been called to the necessity of preventing fire and panic in public places of entertainment. A committee was appointed by the Bench to examine carefully into the matter, and they had the advantage of the assistance of the engineer and surveyor to the Corporation, who went into the question thoroughly and made reports upon the subjects. The committee appointed had taken a great deal of pains both by personal inspection and the reports of professional gentlemen. A number of regulations and alterations were prescribed, which were agreed to very cheerfully and properly by the lessees of the theatres. A great many of these were carried out in a very satisfactory way, but some of these remained to be done. They would take the theatres in order. Mr. Sheldermine would refer to them, and it would be for the Bench to determine if in case the requirements were not satisfactory, whether they should give a full license now or only a provisional one until the alterations were carried out.

The applications were then heard and granted.

Admiral Gough, at the close of the business, moved the following resolution:—That the thanks of this special meeting of justices assembled for granting theatre licenses in the city should be tendered to the chairman and members of the committee who were appointed to inspect the said theatres for their

valuable services and labours, completed with such satisfactory results.

Dr. Costine seconded the motion, which was adopted.

The Chairman, in reply, said the committee had acted in this matter with a deep sense of their responsibility. The public might now rest assured that they could go to the theatres with the full confidence that everything had been done in the way of structural alterations to prevent danger in case of fire. He would only say to the public who went to the theatres that in case of an outbreak of fire they should sit still. If they did not do so, and made a rush, they would create a panic, and if anything happened to them it would be their own fault. The theatres were now in a safe condition if reasonable precautions were taken.

#### BURNLEY TOWN HALL CLOCK.

THE clock and bells for the new town hall at Burnley, which was opened on Saturday, have been supplied by Messrs. W. Potts & Sons, of Leeds. The clock shows the time on four external dials, 7 feet  $1\frac{1}{2}$  inches each in diameter, made of skeleton cast-iron frames to form the circles, minutes, and figures, and glazed with white opal glass, behind which are patent gas-burners and reflectors. The hands are of strong copper, balanced or counterpoised within four sets of strong dial or motion wheels for carrying the hands of gunmetal, cut and polished on the engine, and mounted in strong iron frames. There are also large bevel wheels, mounted in brass bushed iron frames, also double and single universal joints of gunmetal. The clock is constructed on the solid horizontal cast-iron bed frame, the top of surface of which is planed perfectly flat, so that all the necessary fittings can be properly adjusted; there are also two index dials inside the clock-chamber to set the outside hands by, the one showing the seconds, the other the minutes, as at the Cathedral, Lincoln, the first of the kind in the country, which was designed and first brought out by Messrs. Potts & Sons, of Leeds, the makers of the town hall clock, who also made the Preston, Bolton, Rochdale, Wakefield, Hyde, New Mills, Newbury, and Lerwick Town Hall clocks. The main wheel is 15 inches in diameter of the going part, cut on the engine, and of solid gun-metal, with Lord Grimthorpe's maintaining power attached on the bolt and shutter principle for keeping the clock going during the time of winding up, and so arranged that the attendant cannot put the key on without putting the power in gear, or take the key off till power is

removed. The going part will go eight days with once winding. The escapement is the double three-legged gravity by Lord Grimthorpe, same as in use at the Parliament House, Westminster, Rochdale Town Hall, Leeds Royal Exchange, &c., and one now making for the county magistrates, for the Prestwich Asylum, Manchester, by Messrs. Potts & Sons, Leeds. This escapement, if properly made, is one of the finest ever introduced for enabling a clock to keep correct time. The pendulum is compensated with zinc and iron tubes with steel rod through the centre, and cylindrical shaped bob of about 2 cwt. beating every  $1\frac{1}{4}$  seconds, also an engraved degree plate. The striking part for the hours, large or main wheel, is of gunmetal, cut and polished on the engine, and fully 18 inches in diameter, with necessary cams attached, faced with steel, for lifting the hour hammer that strikes on the large or tenor bell of about 25 cwt. The Westminster chimes are struck on the four smaller bells, which weigh over 32 cwt. The total weight of hour and quarter-past bells altogether is 56 cwt. 1 qr. 23 lbs.

#### ALL SAINTS, WEST DULWICH.

THE foundation-stone of this church was laid on Wednesday by the Bishop of Rochester, about 900 people being present. The site of the new church is a fine piece of land given by the Governors of Dulwich College, and is most conveniently situated within five minutes' walk of the L. C. and D. Railway Station, Dulwich. It is triangular in form, and has a fall from west to east of about 28 feet. The architect has tried to utilise this very considerable fall so as to add great dignity to the east end and enhance the general effect of the church.

The main scheme of plan shows a wide and lofty nave of proportional length. There are seven double-arched bays, the shafts and main arches being carried up in red brick, with stone caps, bases, and bands; the remaining portions of walling being of yellow brick, relieved here and there with red brick and stone bands. Spaces for colour decoration are placed immediately over the lower arches, and a clerestory is formed in spandrels above. The three easternmost arches open into wide north and south aisles, which are gable-roofed. An apsidal baptistery, with north and south narthex at sides, is thrown out at the west end immediately under a row of five single windows and a large rose window in western gable. Two towers placed anglewise, and pierced with arches on all four sides, flank the great chancel

# FIRE! FIRE! FIRE!

## GRIFFITHS' "PYRODENE" FIREPROOFING LIQUID

(NON-POISONOUS).

Transparent Liquid for Rendering Woodwork Uninflammable,

Without altering its appearance, and where Painting is not desired, such as Wooden Fittings in Exhibitions, Churches, Pews, Matchboarding, Theatre Scenes, Wooden Stairs, Joists, Beams, Floors, Factories, Stables, Mills, &c., in fact, Structures of an inflammable nature of all descriptions. Acts as a priming for new Woodwork for Paint or Varnish. Also for rendering Theatrical and Ball Dresses, Curtains, Paper, Felt, Canvas, &c., perfectly uninflammable.

Griffiths' Liquid penetrates the pores of the wood. It lasts as long as the wood itself. It prevents Dry Rot and decay in house timbers. It does not crack, peel, or rub off.

It is perfectly innocuous and free from smell. It will keep any length of time. Any one can apply it. One gallon will cover double that of any other priming.

AND

All Woodwork in new houses should be fireproofed with this liquid, the cost is so trifling in comparison with the preservation of the timber and freedom from risk of fire. If work is desired to be painted afterwards, Griffiths' Pyrodene Paint is best for the purpose.

## GRIFFITHS' "PYRODENE" FIREPROOF PAINT.

READY FOR USE. NON-POISONOUS. ALL COLOURS.

This Paint is manufactured for preservative and decorative purposes equally as for its FIRE-RESISTING qualities. The Fireproof Paint and Fireproofing Liquid is used at some of the principal Theatres in the United Kingdom.

#### RECENT TESTIMONIALS.

From Messrs. MAXWELL & TUKE, Architects, 29 Princess Street, Manchester: December 28, 1887.

DEAR SIRS.—We used your Paints in nearly the whole of the works for the Royal Jubilee Exhibition, and with very satisfactory results.

Yours truly, MAXWELL & TUKE.

To Messrs. Griffiths Bros. & Co., Dashwood House, London, E.C.

From S. C. LOWE & SON, House Decorators, 32 Cavendish Street, Stretford Road, All Saints, Manchester: November 22, 1887.

DEAR SIRS.—In reply to your inquiry, we, as one of the contractors for the painting of the Manchester Jubilee Exhibition, which closed on the 10th of this month, have pleasure in stating that both your "Aguol" Paint, and also your "Pyrodene" Fireproof Paint, have given great satisfaction. We found them work easily with a covering power of from 30 to 40 per cent. over ordinary paint. Although applied during intense frost, and having been subjected to an almost tropical summer, followed by the drenching rains of this autumn, they are as fresh in colour and have as firm a grip as when applied, and appear quite unaffected by the nine months' exposure. We consider them, therefore, well adapted for all work in any climate.—Yours truly,

To Messrs. Griffiths Bros. & Co., London.

S. C. LOWE & SON.

CHEAPER AND MORE DURABLE THAN ORDINARY PAINT.

GRIFFITHS' "PYRODENE" FIREPROOFING COMPANY, Limited,  
4 & 5 DASHWOOD HOUSE, NEW BROAD STREET, E.C., LONDON.

arch north and south. It is important to note that by this uncommon form of plan, a view of the altar is obtained by those occupying seats in the north and south aisles. The chancel, which is the same height as nave, is pentagonal in form at east end. It is divided from nave by a very lofty arch, the upper portion of which is filled with rich tracery, forming a sort of lacework of stone, carried on two slender shafts, the basis forming portion of a low chancel screen. A kind of rood screen is formed of wrought-iron, about 30 feet from nave floor, which, whilst acting as a constructional help, adds greatly to the general richness of effect. It is considered that this screen will be one of the marked features of the new church. The eastern walls of chancel will be enriched by seven lofty three-light windows, the heads being filled with tracery. An arch on the south side divides the chancel from the vestries and the organ-chamber, and another on the north side from the ambulatory and chapel and gallery for musicians or additional choir.

An ambulatory running round eastern wall forms a connection between chapel and vestries, musicians and organist. At the east end of north aisle is formed a complete chancel and sanctuary, which, together with north aisle, accommodating as it will about 200 people, forms almost a complete small church, with separate entrances for clergy and laity. This portion of the church will be heated and lighted independently of the main building. The nave floor being 28 feet above the ground level at east end, ample room is gained in the basement for a large crypt, which is designed to be used for various parochial purposes.

The main features that the architect has tried to realise in the exterior have been, firstly, loftiness throughout; secondly, to take every advantage of the fall in site to get as grand an effect as possible at the east end; thirdly, to group the principal parts of the building as picturesquely as possible.

With the means at his disposal the architect saw he could not hope to build a tower or spire of large dimensions, and therefore has designed a kind of minaret tower which, while it is in accordance with the feeling of the design generally, is sufficiently large to admit of a peal of bells. A flèche of very considerable height is placed on the centre of roof at the junction of the nave and chancel.

The church when finished will accommodate about 1,400 adults. The entire work is designed by, and is to be carried out under the superintendence of, Mr. George H. Fellowes Prynne, A.R.I.B.A., of London. The present contract only

includes the foundations of a small portion of the east end put in for the purpose of laying the foundation-stone on the eve of All Saints' Day, the contractors being Messrs. Kynock & Co.

The contract plans for the complete work are now being prepared, and the work will be proceeded with as soon as possible after the invited tenders have been received.

#### REGISTRATION OF PLUMBERS.

AT the examinations of plumbers for registration, just held at the City and Guilds Institute, applicants were present from several towns of North and South Wales, from Somerset, Stafford, and Hants, as well as from various parts of London and district. The examinations embraced tests of joint-making, lead-laying, &c., and a set of questions relating to the qualities of materials, the construction of various forms of house-fittings, and the principles of sanitation. The examiners were Messrs. Hudson, Webb, Millis, Clarke, and Lyne, the two last representing the Polytechnic Plumbing Classes and the United Operative Plumbers' Association respectively. Just half the applicants succeeded in passing the examinations.

At a meeting held yesterday at the Guildhall the Plumbers' Company issued their certificates of registration to plumbers from Bath, Battle, Brighton, Brynmawr, Burnham, Cardiff, Chester, Chippenham, Egham, Emsworth, Halifax, Hereford, Kirkby Lonsdale, Landport, Manchester, Salisbury, Sheffield, and Southampton.

#### WENHAM LAMP COMPANY.

THE first ordinary general meeting of this company was held on Tuesday at Winchester House, Old Broad Street, London. Mr. D. A. T. Christie (chairman) stated that the shareholders would notice that although the company only dated from May last, the accounts had been made up as representing a whole twelve months, in order that the business might be a continuous one, with practically, if not technically, the same proprietary. It was satisfactory that the normal charges were substantially less than in the previous year, and in the current year there would be a still further reduction. The manufacturing gross profit was 28,561*l.*, or a falling off of 9,800*l.* compared with the previous year. Of this amount 1,500*l.* at least was attributable

to the rise in the price of metal and the increased discounts to the trade, but the real disappointment had arisen entirely from the Continental department, especially France. They had, in consequence of certain ill-advised transactions, found it necessary to reorganise that Branch; both in France and Germany they had various local difficulties to contend against. They had during the past year, notwithstanding the falling off in the Continental department, sold 3,000 lamps in excess of the previous year. The net profit had amounted to 13,175 $\frac{1}{2}$ l., the directors had paid an interim dividend of 5 per cent., and they proposed to apply the sum of 2,000 $\frac{1}{2}$ l. in the reduction of patents and business purchase account, and to recommend a present distribution of 3d. per share, making a distribution for the year of 6 $\frac{1}{4}$  per cent on the capital. The report was adopted, and the dividend as recommended declared.

#### AMERICAN NOTES.

IN Philadelphia underground brick conduits, 8 feet high and 4 feet wide, are being constructed for the electrical wires in the main streets and avenues. In these will be 50 3-inch pipes, each containing 100 wires. One connection will be made in each block, with a main from the conduit under the house line to the middle of the block, where a tall pole will distribute wires to the rear of the houses. Powerful pumps will keep the conduits full of dry air.

It is noted by *Building* of New York that the *Sun* has published an interesting article on the architecture of residences on the west side of Central Park, and other recent additions to the more important residential structures of the city. In enumerating a number of the more impressive edifices about completed, it contains some pertinent remarks, but to our minds, *Building* says, the utility of the entire article is lost from the fact that while owners' names are given, no architect is mentioned. It is disappointing to find that an article of such merit should be spoiled by the fact that the writer passes over the most important information which the public should have, viz. the name of the author of the building he criticises.

ONE of the most satisfactory features in the completion of the twin spires of St. Patrick's Cathedral, the same journal states, is the fact that, although the work of building them above the roof level has been going on since the fall of 1885, not a single accident has happened to any person employed in

the undertaking. The spires are of white marble throughout, except that a copper rod through the centre holds the extreme upper pieces composing the finial in place. They are octagonal in form, mounted on octagonal lantern towers that rise from the level of the roof. They are the tallest church spires in America, and rank among the tallest in the world. They measure about 330 feet from the curb, while Trinity spire in this city is but 284. The spires have been erected under the supervision of the architect employed from the conception of the cathedral, Mr. James Renwick.

In an article in the *Scientific American*, by Mr. Robert E. Masters, on "Melting Iron," the following passage occurs:— I have before me about all the reports of cupola workings that have been published for several years past, and I find among them a number from men who claim, with cupolas of 35 inches to 40 inches inside diameter, and in heats of less than 18,000 pounds of iron, to be able to melt from twelve to over nineteen pounds of iron to one pound of fuel. For instance, the following figures look well on paper:—

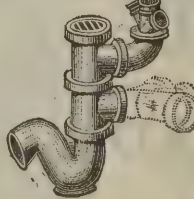

Amount of Iron Melted.	Amount of Fuel Consumed.	Ratio of Fuel to Iron Used.
17,920 pounds	1,232 pounds	1 to 14.54 pounds
9,800 "	635 "	1, 15.43 "
8,800 "	530 "	1, 16.60 "
10,700 "	610 "	1, 17.54 "
13,100 "	680 "	1, 19.26 "

Simply because I have not been able to reach these high figures, or see anyone else do it, I do not say that it cannot be done. I try to be progressive, and am a thorough advocate of any improvement in machinery or advancement in mechanical work, but I am not going to try to compel any man who is in my employ as foundry foreman to produce results in melting iron that are beyond anything I have known to be accomplished. I would like to see some of these figures demonstrated, and I am now talking to the men who claim to produce them. I will present any man with 250 dols. who will come to our works (Marshall, Texas) and melt 18,000 pounds of iron in a 38-inch cupola at a ratio of over 14 pounds of iron to one of fuel, and have the metal fluid enough to produce good, clean, solid castings for locomotives, architectural work, and machinery. These figures will give the

one who undertakes it the highest amount of iron to melt and the lowest ratio of iron to fuel given in the above table. I will furnish as good, or better, cupola to melt in than can be found in the average foundry: good blast, first-class dry Connells-ville coke, Scotch and American pig-iron, and a regular run of car and locomotive cast scrap. All I ask is to do the weighing on the charging-floor and keep the figures jointly with the man who is to accomplish it, and I will take pleasure in publishing the results.

### AN AMERICAN CHIMNEY.

THE *Scientific American* gives a description of the great chimney recently erected at Kearney, near Newark, N. J., by the Clark Thread Company. It possesses the distinction of being the tallest chimney in America, and the fourth tallest in the world. It is the highest chimney ever built for boiler furnaces. The others that surpass it in altitude were erected for carrying off the products of chemical processes and for distributing the noxious gases produced.

The shaft is circular, and rises with a perfectly uniform batter from the bottom to the neck below the cap. Its diameter at the base is 28 feet 6 inches, and at the neck is 14 feet. This gives a batter of 7 feet 3 inches, or 2·85 inches for every 10 feet. Its total height is 335 feet. Its internal diameter is 11 feet, giving one circular flue. At the summit it expands into a well-proportioned capital surmounted by a cast-iron coping. The latter weighs 6 tons; and is composed of thirty-two sections. They are bolted together by inside flanges, so as to present a smooth exterior.

The foundation is in concrete. The ground was excavated until a layer of firm gravel was reached, 1 foot below the water. Upon this the concrete was deposited. It was composed of crushed limestone 6 parts, sand 3 parts, and German Portland cement 1 part. It is 40 feet square and 5 feet deep, forming a block of 8,000 cubic feet volume, and weighing about one million pounds.

On this the base was started, composed, like the shaft proper, of brick laid in cement mortar. For this portion, up to 4 feet above the ground, a mixture of 1½ parts sand to 1 part German Portland cement was used for the mortar. The shaft up to a height of 160 feet is laid with the following mixture:—Sand 6 parts, lime 2 parts, and cement 1 part. The sand and lime were made into mortar, and had stood three months

before use. This method of treatment is considered to improve the quality of the mortar. Just before use the cement was added. From this point up the proportion of cement was increased until, at the top, the proportions became, sand 3 parts, lime 1 part, and cement 1 part.

Two qualities of brick were used. The outer portions were of the first quality North River, and the backing up was of good quality New Jersey brick.

Every twenty feet in vertical measurement an iron ring, 4 inches wide and ¾ to 1 inch thick, placed edgewise, was built into the walls, about 8 inches from the outer circle.

As it starts from the base the chimney is double. The outer wall is 5 feet 2 inches in thickness, and inside of this is a second wall 20 inches thick and spaced off about 20 inches from main wall, and, of course, concentric with it. From the interior surface of the main wall eight buttresses are carried, nearly touching this inner or main flue wall, in order to keep it in line should it sag. The interior wall, starting with the thickness described, is gradually reduced until a height of about 90 feet is reached, when it is diminished to 8 inches. At 165 feet it ceases, and the rest of the chimney is without lining; no fire-bricks are used in the lining.

As the chimney receives two horizontal flues placed diametrically opposite to each other, a 12-inch deflecting wall is built across the vertical shaft, starting from the base and rising 16 feet. The plane of this wall is perpendicular to the axis of the flues.

The two flues just alluded to are arched tunnels 7 feet wide and 8 feet high. An arched opening is formed for their entrance into the chimney, and a space of 2 inches is provided between the outside of the flue and the main structure. The walls of the horizontal flue as they enter the stack are 16 inches in thickness.

In these flues it is proposed to place feed-water heaters for the boilers. About one thousand pipes will be included in them. It is believed that much more of the waste heat can be economised than is usual, as, owing to the great height of the chimney, a comparatively slight heat in the products of combustion will generate ample draught. The advantage, in an engineering sense, of so large a chimney will be derived from this factor of economy.

Twenty-one boilers of 200 horse-power each will depend upon the chimney.

The general methods of construction adopted were characterised by simplicity as well as by efficiency. A steam

elevator, with a platform 3 feet 6 inches by 3 feet, was arranged to run up and down inside the shaft. It had 3,000-lbs. capacity, but never had to raise more than 800 lbs. Two uprights, 4 by 6 inches, were braced against the inside walls, and served as guides to the elevator. As the work progressed, these and other fixtures of the elevator were carried up, until finally the crane, carrying the main sheave, was above the coping nearly 340 feet from the earth. Interior scaffolds were built every few feet as the work progressed, two beams, 3 by 8 inches, being built into the walls to carry each one.

The greater part of the main shaft and lining was executed by eight bricklayers and five helpers. Their material was supplied from below by seven labourers on the ground. A system of bell and flag signals was arranged, so that no confusion could exist, and the men below could tell at once what material to send up in the elevator.

Two operations were needed to keep the chimney true. The circle had constantly to be verified or trained. By accurate plumbing a series of centre points were carried up, one being established at every 40 feet of height. From the line of those representing the axis of the shaft the training was done. The other operation was the plumbing. The batter or slope being a constant, a mason's plumb rule was planed off to give the true slope, and the sides were constantly tried with this. Both these operations were in charge of one man, who constantly was training or plumbing. By many hours of practice he acquired the art so perfectly that he never looked to the ground, his eye not ranging below the end of his rule.

Eventually the chimney was plumbed from a height of 300 feet, a 40-foot plumb-bob being used. The deviation from the vertical was practically imperceptible.

The foundation, base, and 18 feet of the shaft were built in December 1887. The work was then closed in for the winter. Operations were resumed in April 1888, and continued when the weather permitted. The brickwork was completed in September. Altogether 150 days of 9 hours each had been devoted to the construction—a remarkably short period for so great a work.

The total weight of the chimney is put at 5,000 tons, divided as follows:—

Brickwork	9,051,899 lbs.
Concrete	1,000,000 "
Ironwork	40,000 "
Total	10,091,899 lbs.

The bearing surface is 1,600 square feet, giving about 2·8 gross tons per square foot, or more exactly 6,312 lbs. The total number of bricks in the stack is 1,697,231; 201,000 were used in the base and foundation, and 66,277 in the caps.

No means are provided for ascending the chimney after the elevator is removed. Should it become necessary to do so, a balloon, with a line, can be sent up through the central flue and allowed to lose its gas and descend on the outside. This will provide means for drawing up a line of sufficient size to enable a man to ascend the shaft.

We append some dimensions of the three chimneys that exceed this one in height:—

<i>Townsend's Chimney, Glasgow, Scotland.</i>	
Height from ground to coping	454 feet
Outside diameter, at ground	32 "
" " " top	13 " 4 inches
Thickness of wall at base	5 " 7 "
Cost	£8,000

<i>Tennant &amp; Co.'s Chimney, Glasgow, Scotland.</i>	
Height from ground to coping	435 feet 6 inches.
Outside diameter, at ground	40 "
" " " top	13 " 6 "

<i>Dobson &amp; Barlow's Chimney, Bolton, England.</i>	
Height from ground to coping	367 feet 6 inches.
Octagonal in section.	
Outside diameter, at base	33 " 10 "
" " " top	13 " 2 "
Cost	£3,000

Over three years were devoted to the building of the Townsend chimney. Tennant & Co.'s was built in one year.

The Clark chimney was erected by the company, under the superintendence of their foreman, Mr. Cunningham. It cost 30,000 dols. The builders have allowed for about 6 inches of sway, which is about the amount of motion anticipated during a violent blow.

#### CENTRAL STATION ELECTRIC LIGHTING.

For some little time past there has been growing up on the banks of the Thames at Deptford a structure of somewhat colossal proportions for those parts, being about 200 feet square and close upon 100 feet high. This building is the combined

engine, machinery, and boiler-house for the central lighting station of the London Electric Supply Corporation, which bids fair to be one of the most remarkable industrial establishments of the metropolis. The object is to supply London with the electric light, and to this end the corporation have laid down lines for the eventual supply of two millions of lights from this great central station, from which they will be able to convey the electric current to all parts of the metropolis. It is, however, for the future to witness the possible completion of this gigantic installation. For the present the corporation is erecting plant and machinery for the supply of 250,000 glow lamps; the building now under construction, however, will be capable of containing the necessary machinery for four times that number. Before proceeding to describe this enormous electrical plant it may be as well to note the small beginnings of which it is the outcome. Some four years since Sir Coutts Lindsay decided to light the Grosvenor Gallery by electricity, and when this became known many in the neighbourhood requested him to enlarge his proposed installation and to supply them with the electric light. This demand went on increasing, until at length a small company was formed and a large central generating station, which is known as the Grosvenor station, was built and equipped. From that station the electric current is now being supplied to some 33,000 lamps, the area covered extending from Regent's Park on the north to the River Thames on the south, and from the Royal Courts of Justice eastwards to Knightsbridge westwards. The whole of this extensive area is effectually supplied with the electric current by five separate circuits. The success thus attained only led to a greater demand for the electric light, and the small company became merged in the present corporation, which consists of a very few subscribers, who have hitherto found the necessary capital among themselves and intend to find it up to 1,000,000, that being the authorised capital.

The Deptford station is being built on a riverside site of about four acres in extent, known as Stowage Wharf, nearly the whole of which it is expected will be eventually covered by the engine and machinery houses. The buildings at present being constructed occupy a space of 210 feet by 195 feet, with a height of about 100 feet. The boiler-house, which is nearest the river, is 195 feet long by 70 feet wide, and is constructed to contain boilers of 65,000 horse-power. Of these boilers, which are of the Babcock & Wilcox tubulous type, a number are now being erected, which will supply steam for engines of 13,000 horse-power. These boilers are arranged on two floors, the

fuel store being on a third floor. The coal will be delivered from the colliers alongside a substantial wharf on the river, and will be run up in trucks by rail to the store, and delivered thence by gravity to the boiler furnaces. The engine-houses now being built are two in number, each being 195 feet long by 66 feet wide. They are separated from the boiler-house by a wall of masonry and from each other by iron columns. In the first engine-house a pair of engines of 3,000 united horse-power will be shortly erected. These engines are of the compound Corliss type, and are being supplied by Messrs. Hick, Hargreaves & Co., of Bolton, who will supply the other engines and machinery. These engines will drive two Ferranti dynamo machines, each capable of generating the current for 25,000 glow lamps. These will be by far the largest electrical generators that have yet been constructed. They will, however, be greatly eclipsed by the large dynamos which are to follow in the second engine-house. Of these there will be two sets, the dynamos being combined with the engines and driven direct. Some idea of the magnitude of these dynamos will be realised when we state that each will weigh 400 tons, and will have an armature 40 feet in diameter. Each dynamo will eventually be driven by a pair of engines of 10,000 horse-power; but at first only half that power will be developed for driving each dynamo, which will primarily supply current for 100,000 lights. When the time arrives for the creation of more lighting power each dynamo will be driven by the full power of the engine, and each will then supply current for 200,000 lamps. The further anticipated extensions will be carried out on the scale of the larger plant. The details of this great undertaking have been worked out by Mr. Ferranti, the engineer to the corporation.

The current—which is known as an alternating current, and is generated at high tension—will be conducted from Deptford to the various parts of the metropolis by means of a novel contrivance which will convey the current to a great distance without material loss, and, what is of more importance, with absolute safety, as has been proved beforehand. The current will be delivered in London at several points, where distributing stations will be established. Here the corporation will have transformers, by which the current will be converted to a lower tension, by which process it will be increased or expanded in quantity very much as compressed vapour is expanded. Thence it will be distributed to the public at a medium tension by other or subsidiary mains, and again finally converted or expanded to low tension on the premises of each.

consumer. In all the arrangements—which we have just been afforded the opportunity of inspecting—ample provision has been made to guard against any interruption in supply that might be caused by the temporary disablement of any portion of the machinery and appliances. It is anticipated that before the end of the present year there will be in actual operation at Deptford machinery capable of supplying 50,000 lights, and by the spring of 1889 200,000 more, making, with those already being supplied by the corporation from the Grosvenor Station, a total of 283,000 lights.

#### HOUSE DRAINING.

A LECTURE was lately delivered at Northampton by Mr. T. Pridgin Teale, M.A., F.R.S., of Leeds, on "Ignorance about House Drains and its Dangers." The lecturer began by remarking that very few houses were in a state of sanitary soundness, and the only way in which this defect could be remedied was by creating a public opinion which should aid those in authority in carrying out the powers with which they were entrusted by the legislature. After stating that he had not lectured for years, and that, therefore, his views were not quite so much up with the times as they should be, the speaker went on to say that much sanitary work was needed in Northampton, as shown by the medical officer's report for 1887, in which it was stated that something like 200 houses were inspected as to the drainage system, with the result that nearly the whole of them were found to be defective. In some instances the medical officer ordered the absolute demolition of the houses, and the report added that the Sanitary Committee had visited these, and ordered that no further action be taken. This implied, said the lecturer, that either the committee had no confidence in their officer or else that they had no confidence in the support of the town. In Leeds last year seventy-six houses were closed, and many of them pulled down, owing to defects in the drainage system. There were three points, continued Mr. Teale, which he wished them to carry away. First, the result of bad drainage was that a large proportion of illnesses arose therefrom, which might be proved by medical men over and over again in the kingdom. Secondly, of houses that had not been recently built under sanitary rules, a very large proportion were wrong in their drainage. Given a house built twenty years ago, they might

almost take it for granted that the drainage was wrong. In Leeds last year 35,000 houses were superficially inspected, and 7,000 found defective; 1,100 were more thoroughly tested, and 927 of them found defective. Thirdly, the question of right or wrong sanitary arrangements in a house was a very simple one indeed when reduced to its proper factors. The wrong system that they had been submitting to in past years was a very complicated and expensive one, whereas the good system insisted upon now was very simple, and much less expensive if carried out when the house was built. Architects and builders, before they were instructed in sanitary matters, seemed to exercise their ingenuity in putting as much of the drainage as possible inside the house. The modern system was to put it all outside, where bad workmanship could do comparatively little harm. To get the work done properly the public should be instructed that they might find out for themselves the A B C of sanitary arrangement, which was not a very difficult matter to learn. The public authorities should then be charged to see that the work was carried out well. The lecturer believed that no systematic code of building laws had yet been adopted in Northampton as there had been in Leeds. He could not understand why such laws had not been made compulsory throughout England. Mr. Teale then proceeded to illustrate, by means of several large diagrams, the effects of bad drainage upon the health of a household, and showed that leaking pipes underneath a building caused the effluvia to rise and enter the house, especially in rooms where there were fires. He showed the danger arising from having sinks, baths, and lavatories connected direct with the drains, and condemned very strongly the bowl-traps, saying that the only effective method was the water-trap. The cardinal principles of sanitary arrangements were that all drains must be outside the house, and disconnected with the pipes leading thereto which should run into gullies, and have a water-trap higher up. The old-fashioned pan-closets were horrible abominations, and ought to be replaced in every instance by ordinary syphons. No drains should run under buildings except where unavoidable, in which case they should be embedded in concrete. The lecturer went on to show specimens of bad workmanship in the joints of leaden pipes in specimens furnished by Mr. Councillor Tomes, and also of cases in which foul gases had eaten holes through the convex sides of curved leaden piping. He also alluded to the grave results that might arise from an escape of effluvia through cellar drains and coming into contact with articles of food, and said that rats were often a sign of direct communica-

tion with drains, and showed a need of remedy. He concluded by saying that all houses, and especially public buildings, should be furnished with plans of the drains, so that they might easily be found when required.

## PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

## APPLICATIONS FOR PATENTS.

15041. George James Randall and Frederick Carter, for "Hardening the faces of all soft oolites, limestone, for the purpose of enamelling same, and producing imitation marble ebonite." October 19, 1888.

15058. Wilhelm Lönholdt, for "Improved valve apparatus, serving either for ventilation or for hot-air supply." (Complete specification.) October 19, 1888.

15074. Alfred Ashmore, for "Improvements in axle pulleys and in axle pulley frames." October 20, 1888.

15132. Richard Stanfield, for "Improvements in pencils, penholders and the like." October 22, 1888.

15136. Edward Cain, for "Improvements in and relating to weather strips of doors for excluding draughts." October 22, 1888.

15142. Hugh Edwards, for "Improvements in locks and keys." October 22, 1888.

15152. James Denham, for "Improvements in brick-making." October 22, 1888.

15176. Lionel Henry Teale, for "Improvements in fire-places." October 22, 1888.

15178. Alfred Robinson, for "Improvements in apparatus in combination with water-waste preventers." October 22, 1888.

15181. Edward Seitz and Sibbett Landells, for "An improved machine for cleaning streets." October 22, 1888.

15221. Charles James Harcourt, for "Improvements in the manufacture of ventilators for oven doors and other like uses." October 23, 1888.

15223. Samuel Russell, for "Window fastening." October 23, 1888.

15235. George Hayes, for "Improvements in and relating to sheet metal lathing and the like, chiefly designed for use in the construction of fireproof buildings." (Complete specification.) October 23, 1888.

15236. John Dewrance and Bonneval Edward Church, for "Improvements in the process of cementing asbestos." October 23, 1888.

15243. John George Witte and William Lewis Witte, for "Improvements in door springs." (Complete specification.) October 23, 1888.

15267. Horace Budge and Frederick John Jackson, for "A device for preventing the opening of doors." October 23, 1888.

15271. William Thomas Leach and Charles W. J. Notte, for "A combined rule, set-square, and section-liner, for draughtsmen and others using drawing instruments." October 24, 1888.

15272. Frederick James Bantin and Charles W. J. Notte, for "Improvements in or relating to overmantels." October 24, 1888.

15278. John Bell Millar, for "Discharge and overflow for baths, sinks, lavatories and similar vessels, to be named or called 'The Luxor.'" October 24, 1888.

15355. David Richmond, for "Improvements in the construction of drain-pipes." October 25, 1888.

15361. Andrew Nicol Porteous, for "Improvements in rotary engines, applicable to water meters, pumps, and blowers." October 25, 1888.

15379. John Crosby Hargreaves and Alfred Robert Armitage, for "Improvements in firegrates." October 25, 1888.

15389. Alfred Winrow, for "Improvements in machinery for pressing or stamping tiles or bricks." October 25, 1888.

## PROVISIONAL SPECIFICATIONS ACCEPTED.

11392. William Price and Edward Webb, for "Improvements in apparatus for gas-lighting, warming, and ventilating." August 7, 1888.

12470. Gurney Lindoe Falconar, for "An improved method of framing sash-windows, doors, or shutters." August 30, 1888.

12583. George John Bellingham, for "Improvements in portable alarm fastenings for doors or windows." September 1, 1888.

BOX TUNNEL, G. W. RAILWAY (East End).  
CORSHAM DOWN QUARRY (Entrance from Railway).

## BATH FREESTONES.

We are prepared, as heretofore, to supply these sound  
and fine Building Stones on terms advantageous to Buyers.  
Orders promptly executed, and Blocks selected to suit  
all requirements.

Prices quoted by return of post, and all letters to be  
addressed to

YOCKNEY & CO. (Sole Owners,

CORSHAM DOWN QUARRY,

CORSHAM, WILTS.

Note.—No Connection with the other BATH  
STONE FIRMS.

12660. Thomas Bloomfield Secker, for "Improved automatic door-holder." September 3, 1888.

12946. Timothy Line and James Daveney, for "Improvements in wainscots and linings for walls, ceilings, and the like." September 7, 1888.

13211. Jesse Rust, for "An improved vitreous material for paving and other purposes." September 12, 1888.

13243. Andrew Turnbull and John Mathieson, of the firm of Turnbull, Mathieson & Co., for "Improvements in stoves and cooking-ranges." September 13, 1888.

13309. John Henry Abel, for "Improved spring-check, stop and alarm apparatus for doors." September 14, 1888.

13553. Franz Wengel and Wilhelm Cronmeyer, for "A novel construction or arrangement of affixable table for draughtsmen, engineers, and general drawing-board supporting purposes." September 19, 1888.

13633. William Charlesworth, for "Improvements in window fastenings." September 21, 1888.

13643. William Snelgrove, for "Improvements in circuit making and interrupting devices for electric bells and other purposes." September 21, 1888.

13696. Charles Herbert Scott, for "Improvements in brick-kilns fired by gas." September 22, 1888.

13977. Alexander de Guerra, for "Improvements in opening and closing window-sashes." September 28, 1888.

14073. Robert Hyde, for "Improved apparatus or means for raising and lowering sliding windows or sashes (or shutters) in railway-carriage, cab, or other doors, or sliding windows, or sashes or shutters in houses or buildings." October 1, 1888.

14198. Stephen Francis Smith, for "An improved combined ventilator and gas bracket for walls." October 3, 1888.

#### COMPLETE SPECIFICATIONS ACCEPTED.

Notice is hereby given, that all persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the date of the official *Journal*, give notice at the Patent Office in the prescribed form of such opposition.

16061. Robert Harris Reeves, for "Improvements in the construction and ventilation of soil pipes, house drains, or other sanitary fittings." November 22, 1887.

16165. Benjamin Lewin Mosely, for "Improvements in pavement kerbs, conduits, and road gutters." November 24, 1887.

16418. Frederick James Baynes, for "Hood or damper for domestic fireplaces, either for warming or cooking." November 29, 1887.

17588. Henry Arthur Ball, for "Improvements in apparatus for opening and closing fan-lights and the like." December 21, 1887.

17630. James Bingham Allcott, for "Improvements in or pertaining to the disposal of refuse of towns, and the like, by burning, utilising heat generated therefrom, and apparatus therefor." December 22, 1887.

118. Stephen Brooks, for "Improvements in and connected with smoke consuming arrangements for steam boiler and other furnaces and domestic fireplaces." January 4, 1888.

12460. Thomas de Garis Cohn, for "Improved means of fastening or securing window-sashes." August 29, 1888.

#### PATENTS SEALED, OCTOBER 26, 1888.

11300. William Green, for "Improvements in apparatus for raising water for the supply of public or private baths, street watering, flushing sewers, and other purposes." August 18, 1887.

12341. Edward Kirby, for "Improvements in window fastenings, commonly known as sash or casement fasteners." September 12, 1887.

13786. Thomas William Helliwell, for "Improvements in the means or method of fixing and making secure sheets of glass, zinc, slate, or other suitable material employed in covering the roofs, flats, or sides of railway stations, green-houses, or other structures or places where adaptable." October 12, 1887.

13885. Alfred George Wass, for "A new or improved combination of substances for the manufacture of varnish, paint, enamel, or other similar articles." October 13, 1887.

13902. Robert Punshon, for "Paving, roofing, and flooring material." October 13, 1887.

14056. John Edward Beanland, for "A new or improved hinge or connection adapted for either doors, gates, or windows, and means or method of fixing same." October 17, 1887.

TO INVENTORS.—Patents for Inventions, Trade-marks, and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & CASSELL, Patent Agents, 43 Southampton Buildings, Chancery Lane.

*This work will be presented to EVERY ARCHITECT whose name appears in "The Building Trades Directory for England, Scotland, and Wales."*

## THIRD YEAR OF ISSUE. THE ARCHITECTS', SURVEYORS', AND ENGINEERS' COMPENDIUM, AND COMPLETE CATALOGUE.

EDITED BY JOHN ED. SEARS, A.R.I.B.A., F.A.S., AND C. STANLEY PEACH.  
ILLUSTRATED BY MAGNIFICENT PLATES.

#### IMPORTANT NOTICE.

The next issue will contain a **DICTIONARY OF MANUFACTURERS' SPECIALTIES**, and the Editors will be pleased to receive particulars or catalogues of goods, with the leading specialties marked. Names of approved specialties are inserted **WITHOUT CHARGE**. The special feature of the work is **THE COMPLETE CATALOGUE**, in which detailed and priced particulars of goods, with each article indexed, are brought together and classified for the reference of Architects, Contractors, and others.

#### TESTIMONY OF MANUFACTURERS.

**NOTE.**—Of the Firms who have already taken space, **Seventy** have ordered from 1 to 8 pages and upwards each, and the following and others have taken greatly increased space:—

D. Bostel, 1 page (increase from  $\frac{1}{2}$  page).

Broad & Co., 8 pages (increase from 1 page).

Burt & Potts, 2 pages (increase from  $\frac{1}{2}$  page).

Doulton & Co., 2 pages (increase from  $\frac{1}{2}$  page).

Maw & Co., 2 pages (increase from  $\frac{1}{2}$  page).

Richardson, Ellson & Co., 2 pages (increase from  $\frac{1}{2}$  page in first and 1 page in second issue).

S. Saunders, 1 page (increase from  $\frac{1}{2}$  page).

J. Wright & Co., 2 pages (increase from  $\frac{1}{2}$  page).

Hitchins' Fireproof Plastering Co. write:—"Was of great service to us. We can distinctly trace several good orders to it."

James Brown writes:—"Has resulted in business with several firms in the course of the year."

Thos. Gregory & Co. write:—"We have proved its worth." "We find that a great benefit has accrued to us from this excellent method of advertising."

#### SPECIMEN OPINION OF ARCHITECTS.

R. Norman Shaw, Esq., R.A., &c., writes:—"I am quite certain it would be of the greatest value, and secure universal support. Manufacturers' Catalogues are of very little use, and go freely into the waste-paper basket, as they are so numerous that it would be impossible to keep them, and unless kept systematically they would be of no use. At least, I know when I set to work to find a name or address I rarely succeed."

Full particulars of JOHN E. SEARS, 16 NEW BRIDGE STREET, LONDON, E.C.

# ART DECORATORS AND FURNISHERS.

## High-class Furnishing Art Decorations.

# THE "THOMAS" LAMP.

Lighting Power with  
ordinary London Sixteen-  
Candle Gas, from tests  
taken by Professor Wm.  
Foster, M.A., L.R.C.S.

No.			
10.	11.4	Candle-power	per foot.
11.	12.5	"	"
12.	12.5	"	"

These Lamps are made in three  
sizes, Nos. 10, 11, 12.

These Lamps can be obtained through Gasfitters, Ironmongers and  
Merchants. Foreign Orders through Merchants only.

The advantages of this Patent  
over other existing Lamps  
are:—

Small consumption of Gas  
with great Illuminating power.

No possibility of the Burner  
corroding or getting out of  
order, as is the case with other  
generative gas lamps.

The Lamp can be fitted by  
any gasfitter. No fine per-  
forated metal, gauze, or other  
obstructions are used in this  
Patent, as in other lamps which  
are liable to become choked  
through imperfect combustion,  
rendering the lamps smoky and  
useless.

FOR FURTHER PARTICULARS, APPLY TO

**Ridsdale's Railway Lamp & Lighting Company, Ltd.,**  
**55 & 56 MINORIES, LONDON, E.C.**

# The Architect.

## THE WEEK.

THE address which Mr. WATERHOUSE delivered on Monday was worthy of himself. For once at the Institute there was nothing to suggest a chairman of a vestry endeavouring to give importance to very trifling things. Mr. WATERHOUSE, although a president, could not forget that he was an artist, and that artists who keep aloof from Conduit Street were to read his address. It was a suggestive address and a sympathetic one. Many a contractor will be grateful to Mr. WATERHOUSE for what he said about errors in estimates, and his recommendation that justice should be done in such cases. When so much prominence is given to a grievance there is a chance of its removal. In the same spirit was the remark about the very rigorous conditions of the travelling studentships through which six months have to be sacrificed to gain fifty pounds. In speaking of architects who died lately, the longest notice was devoted to H. H. RICHARDSON, who, by "doing exactly what he thought best for his buildings, without going out of his way to look for precedents," may be said to have imitated Mr. WATERHOUSE's practice. Often we hear it said that archæology is ruining invention in architecture, but Monday was the first time for a President to be sceptical about the advantages of eternal copying and adaptation. The subject will bear longer treatment than was possible in the peroration of an address, and we hope Mr. WATERHOUSE will hazard the experiment of giving a special discourse upon Past *versus* Present before the session closes.

THE next session of the Birmingham Architectural Association will begin on the 14th inst. with a conversazione. Mr. APPLETON will read a paper at the following meeting on "The Affiliation of Architectural Student Societies." "The Examination in Architecture and the necessary Preparation" will be the subject of a paper by Mr. F. R. FARROW. Mr. BLASHILL will also come from London to lecture on "Venice." Local support will also be given by Mr. PONTING ("Edington Church"), Mr. WALLIS ("Pompeian Art"), Mr. WARD ("Decorative Art and Fashion"), Mr. TONKS ("The Cross in Art"), MESSRS. KENDRICK and MACCONNAL ("Old Woodwork"). These, with the remaining papers, of which the subjects are not announced, are signs of the efforts now made to enhance the importance of the Society.

AN exhibition of drawings and photographs of architectural subjects and the allied arts will be opened in New York on next Christmas Eve, and closed on January 12, 1889. It is stipulated that the drawings must not have appeared before in any exhibition in the city. They are to be framed or mounted. Drawings will be received at the Fifth Avenue Galleries on December 14 and 15. The exhibition is got up by the Architectural League of New York, of which Mr. J. BEVERLY ROBINSON is president.

WE have maintained that the investigation by the Commission of the affairs of the Metropolitan Board of Works was favourable on the whole to the great body of the members. The interim report, it is now found, takes that view, for the Commissioners admit that the irregularities, so far as disclosed, affected only a small part of the Board's operations, and there was no evidence that malpractice or corruption affected the greater part of the work of the Board, which had really rendered valuable services to the metropolis. Although the conduct of the two members who represented architecture on the Board is censured, it is said there is no evidence to show that any professional employment by them induced them to act at the Board in a manner which they might not otherwise have done. The incapacity of Mr. VULLIAMY, especially during the latter years of his tenure of the office of superintending architect, is noted as contributing to the irregularities of which there were no suspicious circumstances within the cognisance of the Board. The report will be a disappointment

to many; but every one who is jealous of the honour of public bodies will be gratified at finding that the Metropolitan Board has come out so clear from the inquiry.

IN the *Nineteenth Century* for this month Mr. SHAW LEFEVRE has an article on public buildings in London, which is a glorification of his own foresight and good taste at the expense of his predecessors. The conclusion of the article is a recommendation of the project for the erection of a monumental chapel in connection with Westminster Abbey, and for the appropriation of a share of the surplus coal duties to meet the expense. One point is worth attention, viz., the control of the new building. "Every care must be taken," says Mr. SHAW LEFEVRE, "that no sectarian influences should prevail in the future use of the proposed building. It will necessarily be a part of the Abbey, but it will probably be expedient to provide that the building should be maintained or repaired, as in the case of the Chapter House, by the Government, and that the regulation respecting burials in it, or the placing of monuments there, should be subject to the approval of some Minister." In these remarks all will agree, although it would be safer to trust deans of the ARTHUR STANLEY type than a Minister with the magnanimity of Mr. AYRTON. There will also be satisfaction at finding Mr. SHAW LEFEVRE asking whether Mr. BOEHM is not being allowed too great a monopoly of work in the Abbey in this generation.

A SUM of 500,000 francs was voted by the French Chambers for the alterations of the Hôtel de Chimay, which was purchased, in 1885, for the sum of 4,300,000 francs, in order that it might afford room for the ateliers of the adjoining Ecole des Beaux-Arts. It is not easy to foresee the cost of remodelling a building with that object, and the half million of francs is found to be insufficient. In consequence, the contractors have had to diminish the number of workmen, which means carrying out a contract under a loss. It is expected that the Minister will apply for an extra vote, and as it will be bad policy if the Ecole des Beaux-Arts cannot be seen next year in a complete state, we suppose the Chambers will not object to grant the money.

ON Sunday last the French sculptor who bore an almost English name, CHARLES DE GEORGE, died in Paris in his fifty-first year. He was a native of Lyons. In 1866 he obtained the Prix de Rome as a medallist, but soon after his return he set up as a sculptor, and was rewarded by a medal in 1872. The bust of *Henri Regnault*, which forms part of the fine memorial of the painter in the Ecole des Beaux-Arts, was from his hand. His *Youth of Aristotle* gained him a first medal in 1875.

THE firm of Messrs. CROMPTON & Co. has been closely associated with the progress of electric lighting in this country. The position which the firm has attained is suggested by the contracts which Messrs. CROMPTON have undertaken. Among them we find installations in Windsor Castle, Buckingham Palace, the Law Courts in the Strand, the Glasgow Post Office, the Enfield Factory, the Bute Docks, Birmingham Town Hall, the residences of the Duke of WESTMINSTER, Mr. W. H. SMITH, Lord RANDOLPH CHURCHILL, the Attorney-General, Mr. AKERS DOUGLAS, besides factories, banks, clubs, railway stations, &c. To the lighting of the Vienna Burg Theatre, which is the most remarkable example of what can be done with the aid of electricity, Messrs. CROMPTON contributed eleven high-speed engines and eight dynamos of a thousand lights each. Their selection for that work is by itself a testimony of great value. The business of the firm is likely to be increased in proportion to the spread of electric lighting, and, owing to its present magnitude, it is now proposed to hand it over to a limited liability company that will become possessed of the plant and premises in Chelmsford and all interests in the patents which are transferable. It rarely happens that a business is in the market which offers so many advantages to investors. Electric lighting is only in its infancy, and CROMPTON & Co., Limited, should have a large and profitable share in its expansion. There are other applications of electricity which will bring additional commissions to the company.

## THE ARTS AND CRAFTS EXHIBITION.

WHEN RENÉ DESCARTES had completed his studies in one of the first schools of Europe, and was thereby ranked among the wise men of the time, he was, according to his own account, embarrassed by the number of his uncertainties and errors. He resolved to seek after wisdom in ways which were unknown to the philosophers. For that purpose he mixed with men of all conditions, believing that the knowledge which they could impart of the causes which led to success or failure in their affairs would be a better clue to what he sought than anything which was to be found in books or heard in lecture-halls. The first conclusion or sample of wisdom, or, as he would say, of philosophy, which DESCARTES derived from his new mode of study, would not meet with the approval of modern economists. He affirmed that there was less perfection in works which were made by several hands than in those which came from one master. It may seem an odd sort of axiom, and the weakest of all foundations for a new system of philosophy. But DESCARTES was not a fool, and he was able to bring forward many arguments in support of his words, and to demonstrate their importance for all men and in all times.

His system no longer rules, and what he wrote against the co-operation of "divers maitres" in a work will, in our time, be taken as a proof of its absurdity. Everywhere the principle of division of labour, which was so obnoxious to DESCARTES, is accepted as indispensable if there is to be success or, rather, profit. As we are all under its sway, it is difficult to resist the conclusion that the principle must have correspondence with the constitution of man, as seen in a developed state. Without division of labour life would hardly be possible for the majority of us—at least, in the present time, when, as SHAKESPEARE says, "a thousand actions end in one purpose."

It would be useless to ignore that, as in all things human, there are shortcomings in the system of production which now prevails in most parts of the world. A workman or workwoman becomes only a substitute for a machine; he or she can have only a partial, an infinitesimal, interest in whatever he or she helps to make, and in time may degenerate into a "thing of shreds and patches." The desire for recognition, which might be called an instinct, is denied to operatives, their personality is ignored, and they become "hands."

It is not possible to escape from these grievances, but in proportion to the difficulty is credit due to those who make the trial. It is well to show that one pair of hands can work as well in the nineteenth as in the fifteenth century, and that a workman's eyes can see a thing as a whole, and realise his own or an artist's design without any great expense for machinery. Whatever helps in that way keeps up the traditions of humanity. All the novel cannons of which we hear will not enable us to dispense with old-fashioned courage, and it will be an evil day whenever machinery makes men forget that they are endowed with the same powers as the early weavers, smiths, carpenters, and potters, and are under obligation to exercise them.

The Exhibition of the Arts and Crafts Society, which is now open in Regent Street, will reveal the strength of the opposition against what is sometimes called the "commercial system," of which one of the characteristics is production by division of labour aided by machinery, and when co-operation of that sort is not feasible and the work must be produced by one man, declines to recognise him. Evidently the opposition is well supported, for otherwise it would be impossible to bring so many fine objects together. The exhibitors may esteem themselves as a sort of forlorn hope against industrialism as it exists, but if so their attack is conducted under enviable conditions. We see no indications of self-sacrifice. The prices of the objects shown are not marked, but, as in picture-galleries, they "may be obtained from the secretary at the table," a statement suggestive of costliness. But the designers and craftsmen and the manufacturers who employed them deserve to be well paid. The Exhibition is one of the most important in our time, and to a foreign expert it would be more suggestive than some of those which were fifty times its size. He would see there evidence of the skill of English designers unlike any which came before

him in Paris, Antwerp, or Vienna, and the delicacy of the workmanship would dispel all illusions about the two left hands of Englishmen. He would see enough to fill him with apprehension about contests with such rivals. If he were a Frenchman he must believe that his philosophic countryman was right when he spoke of the advantages of having an individuality about a work, rather than tokens of a plurality with as little distinction as a cloud of atoms.

As the Arts and Crafts Exhibition is essentially one of decorative works, the visitor would do well to begin with the North Gallery, which contains many cartoons. Although wanting colour, of which the value is now esteemed, a study of the designs will form the best preparation for an examination of the remainder of the Exhibition. First, they suggest that in decoration, at least, some approach is made towards a style, or perhaps it would be more true to say there is an overstepping of the lines which were supposed to hem in styles. Take, for instance, the designs for stained-glass. Mr. BURNE-JONES's noble *David's Exhortation to Solomon concerning the Building of the Temple* is unlike any of the standard Gothic windows and equally unlike anything in Gouda or Brussels. From the importance given to the draperies, the design is more allied to Greek sculpture. But the arrangement is suggestive of Gothic, although in the figures there is a power which no Mediævalist ever cared to exhibit. Some of the figures might be compared with FRA ANGELICO's in absence of worldliness. From the number of sources to which the picture may be traced, it might be called an example of eclecticism, but of a kind that is very different to what is associated with the CARACCI, and the principle which the drawing exhibits is seen also in many objects throughout the galleries. In the figure of *St. Michael*, which is of heroic size, Mr. BURNE-JONES has had the courage to draw wings which have something of nature about them; the angel is entirely unlike the elegant posturers which are found in Italian pictures. The range of Mr. BURNE-JONES's studies is suggested by two versions of the Crucifixion. In the *Tree of Life* CHRIST is attached to a conventional tree, which, with geometric branches, occupies the entire background, and at the sides are figures of ADAM and EVE. The cartoon for the Birmingham window, probably suggested by the hymn of FORTUNATUS, "Vexilla Regis prodeunt," introduces so many spears and banners around the Cross as to make it seem like an experiment of a modern Frenchman in contrasting rigid with flowing lines.

The chalk studies from the nude, for some of the figures by Mr. HOLIDAY, are signs that the days for conventional figures are past. In his cartoons of *Ecce Homo* and *Christ Bearing the Cross*, we see a pictorial spirit, but with a recognition of the limitations of space. It is difficult, however, to understand why the arms of the Cross should be so short. Mr. SHIELDS, in his cartoons, clothes his figures in drapery which falls in broad folds. His *St. John* is admirable, the head being intellectual. Near it are a couple of figures in fresco, by Mr. AVELING GREEN, of *St. John* and *St. James*, which are painted with breadth, and cannot excite anger when seen in a church. A wide field for this sort of work exists in England. The two figures of *St. Michael* and *St. Raphael*, for Morthoe Church, by Mr. SELWYN IMAGE, show the angels in the capacious robes that are associated with apostles, and which do not appear compatible with wings at the back, or with a two-handed sword. Height is suggested by making the heads small. In these cartoons simplicity is carried to excess.

The experiments of Mr. HEYWOOD SUMNER, for the decoration of the interior of a church in Abergavenny with polychrome sgraffito, are deserving of close attention. The South Kensington experiments have raised a prejudice against sgraffito, and its use is therefore handicapped. The photographs from the building only help in indicating the position of the works, as the church is not well lighted, and we must judge of the effects from the cartoons and specimens. The artist has not hesitated to employ landscape, treating it suggestively. Conventionalism is most suited for sgraffito and avoiding attempts at detail. Two of the evangelistic symbols show how well sgraffito can be applied to that form of decoration. The "fibrous plaster silvered and tinted with lacquers" which Mr. WALTER CRANE sends, is brilliant in effect, but we fear it is the kind of decoration which would be imitated in a vulgar style, and

isolated examples would not be effective, nor would it be easy to work up to them. There are some gesso panels. One by Mr. T. W. HAY resembles an inlay in woods. Another, by Mrs. WYLIE, might, at a distance, be taken for a piece of lace. Mr. CRANE has some cabinet panels, which are Greek in spirit. But, in one way, the piano by Messrs. BROADWOOD, which is ornamented in gesso by Miss FAULKNER, is the most novel application of the material. The detail is fine and the general effect is rich. The question will arise whether the oak case could not be made to look as handsome without coating it with gesso. The piano is one of those things which could not come into existence without an organisation that has a close resemblance to division of labour. Miss FAULKNER designed and executed the decoration, but no less than ten names are given of men who were employed on the case and instrument.

The cassone which Mr. BURNE-JONES has designed and painted is an innovation. The workmanship is excellent. Mr. CHARLES LUMLEY made the chest, and the gesso-work is by Mr. OSMUND WEEKS, who is well represented in the Exhibition. The gilding is as uniform as if received in a dip, like an ordinary colour in a pottery. Comparisons will be made between the garden scenes painted on the cassone by Mr. BURNE-JONES and on a hanging cupboard by Mr. SPENCER STANHOPE, both corresponding in spirit.

The sculpture may not comprise large statues or groups, but in a decorative sense many of the works have much importance. Mr. HAMO THORNYCROFT has a small sketch in relief of his *Artemis*, which in beauty of line affords a lesson in decoration. His sketch of "The ploughman homeward plods his weary way" denotes power in general grouping. Mr. JOHN WILSON has some models of heads, which have the calmness seen in Classic works. His unfinished model of a potshaped vase, with cupids around the brim, will bear comparison with French works of that sort. Two other works, which merit to be commissioned forthwith, are the statuettes by Mr. POMEROY—*In Arcady*, a shepherd boy after cutting a reed, and the *Giotto*, a most difficult figure, ably modelled. The relief in the panel of a balcony designed by Mr. MACKMURDO, and modelled by Mr. KELLOCK BROWN, is graceful in pose and contour, but the figure is overweighted by the massive club, which is out of scale with a reclining figure. The Century Guild of Artists contribute some good panels in plaster by Mr. B. CRESWICK, one series having the "Village Blacksmith" for subject. His frieze in plaster for the Cutlers' Hall is vigorous in the action of the numerous figures, and, from the high relief, will be very effective when produced in bronze. An experiment in tinting sculpture is made by Mr. WHALL, but the tints are so delicate they are hardly appreciable in a public gallery. It is well, however, to find an attempt to solve a perplexing problem.

In architectural decoration there are two pieces of friezes filled with ornament. Mr. PHILIP WEBB has taken a suggestion from Early Greek work, and has leaves which are sharply cut, and at a height the light and shade would be more telling than is possible when seen close to the eye. Mr. MACARTNEY selects as elements some flowers, with few and large leaves, and, being tenderly modelled, form a capital frieze, and one that will be more pleasing than the stereotyped scrolls. Mr. HORSLEY has some panels in this gallery in gesso, which are skilfully designed, and in another part of the building is part of a railing by him, in which flowers in an open and in a closed state are utilised, being both novel and agreeable. In the Northern Gallery Mr. DAY has several of his designs on glass, &c., and some small panels painted on oak. But as the majority of the works in the gallery are big in size, works on a small scale are apt to be overlooked.

In the Upper Gallery they have better chance of receiving attention. A most interesting collection will be found on the walls. First we meet with the water-colour sketches by Mr. F. G. SMITH, of Messrs. CAMPBELL, SMITH & Co., for the spaces above the arches in the Council Chamber of the Guildhall, which are well adapted for the position, and tell their stories at a glance. Head and tail pieces, cleverly designed, are shown by Mr. IMAGE, Mr. HORNE, and Mr. SUMNER. Mr. DAY has several daintily drawn designs for surface decoration, with a frame of designs for the covers of magazines. Mr. WALTER CRANE's original drawings

will be welcomed, for they have rendered the State a service in popularising decorative art. In the large drawings which were prepared for the photogravure series, the painstaking elaboration will surprise people who believe that all such illustrations are dashed off or worked up in a mysterious way during the reproduction. Mr. JACOMB HOOD's name is not often seen on the title-pages of books, but the designs in the Exhibition are charming from their fancy and grouping. The timidity which is seen in parts does not detract from the originality and skilful arrangement. Mr. J. H. POLLEN has several drawings of wall and ceiling painting, which, no doubt, were surpassed in the execution of the commissions. Mr. J. R. SPENCE's *Persophone* is a well-draped figure. Mr. LETHABY has two vigorous sketches of room decoration. Mr. ROOKE and Mr. HAMILTON JACKSON have selected classic legends for some decorative designs. Mr. LONSDALE shows a sketch of part of Cardiff Castle, with his wall-paintings of historic subjects, which are so successful as to warrant further patronage of that form of art. In the gallery will also be found several examples of stained-glass, carving, needlework, &c. The value of the designer's work will be further exemplified when we notice the examples of craftsmanship.

(To be continued.)

#### ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE first ordinary meeting of the Institute of Architects was held on Monday evening, Mr. Alfred Waterhouse, R.A., president, in the chair.

The SECRETARY announced that the absence of Mr. Blomfield, vice-president, was enforced and not voluntary, owing to illness.

Mr. MACVICAR ANDERSON read several letters referring to the passing of the new by-laws, an abstract of which is given in another column.

The PRESIDENT:—It is my duty in accordance with by-law 24 to announce that by a resolution of the Council unanimously passed on July 30 last, pursuant to by-law 23, Mr. James Ebenezer Saunders has ceased to be a member of the R.I.B.A.

#### The President's Address.

The PRESIDENT then delivered the following address:—The task of addressing you, on the opening meeting of a new session, is one which becomes to him, whoever he may be who occupies this chair, more and more difficult. The interesting *Journal of Proceedings* published by the Institute, and our many professional journals, record everything that has happened of architectural interest and moment during the year—successes achieved, new inventions likely to be of service to us, important publications, architectural meetings, and notices of members whose death we have to deplore.

When I look at the addresses given by former presidents on occasions similar to the present, I feel that I cannot hope to say much that is new on the topics which of late years have so much interested you, and which have formed the staple of such addresses, nor approach the ability with which my predecessors have handled these themes. I must ask your indulgence, therefore, if I pass with slight reference many of the questions so ably treated by them, and refer to others, which, if not equally important, have at least been to me the object of some thought.

#### The New Charter.

The most important event of our last session is undoubtedly the passing of the new by-laws under the provisions of the supplemental charter granted last year, though they have not even yet received the approval of the Privy Council. The chief feature of this new instrument is the examination (no longer voluntary, but obligatory) through which for the future the ranks of our Associates will have to be recruited. I look upon this as an immense stride in the right direction, first as an incentive to the student to study, and, secondly, as showing him the direction in which he ought to study, pointing out to him the sources from which he can acquire the knowledge necessary to pass the examination with credit to himself. There has hitherto been, from what I have seen of architectural pupils, not so much a want of will to study diligently as an uncertainty as to the way. The way is now made clear, and from the commencement of his articles the student of the future will know, if he cares to know, what he has to make for and accomplish before he can be recognised either by himself or others as one fit to practise as an architect. This is likely to be of incalculable advantage to our profession, and we owe a debt of gratitude to those who have so long and so earnestly laboured to establish these examinations, and to perfect the

machinery by which they are conducted. May they go on in this good work, gradually raising the standard of requirements, so that in time the examination for admission may completely satisfy the public that those who have passed it are men armed at all points, and ready, so far as their intellectual acquirements are concerned, to do credit to their position as Associates and future Fellows of the Royal Institute of British Architects.

A president of the Architectural Association said, in a recent address, that "the recognition of our profession depends upon each individual one of us." This is most true, and, if lived up to, would incline us, perhaps, to think less of "registration," the advantages of which have been much debated during the past year, some architects thinking it of great importance, and others being strongly of a different opinion. As is well-known to you, an ill-timed, and to my mind most uncalled for, Bill was introduced into Parliament last session, by means of which architects, engineers and surveyors were all unceremoniously to be huddled together in one Act of registration. The Bill would, if carried, instead of narrowing the several professions interested to their most competent members only, have tended, for a generation at any rate, to injuriously widen them by giving a certain legal status to those who otherwise could have no claim as fit to practise in any of them, and in this way would have done incalculable mischief. The Bill was vigorously opposed by the recognised representative bodies of all three professions, and, after a brief but satisfactory debate on the second reading in the House of Commons, was withdrawn; not, however, so far as we were concerned, before considerable trouble and expense had been incurred. The whole scheme was, in my humble opinion, a beginning at the wrong end. Education is what we want—not registration. To the student I would say, prepare for the Institute examination so as to pass it creditably without resort to cram, and so become Associates and Fellows of this body. You will then be registered architects in an effective use of the term. In my opinion we want no other registration, and ought to be content with nothing short of this. We older men, who had none of these advantages, and find ourselves, perhaps, too rusty to pass the ordeal, must be content to offer our experience in lieu of it, and get on as best we may. Our younger brethren have a brighter future before them. The number of students passing last session (sixty-eight) encourages me to believe that they are beginning to appreciate their opportunities.

The article by Mr. Connon, published in our *Journal of Proceedings* in November of last year, is a most valuable contribution to this subject, though, for my part, I should be inclined to try the result of the present examinations for entrance into this body before calling for the compulsory education of all architects. It may at last have to come to that, and then, of course, registration will follow. Let us, in the meanwhile, have as large a body of competent architects to register as possible. The more we have, the more we are likely to have; for, if apathy is contagious at present, the example of successful application towards the attainment of a definite aim will be contagious also. The entreaties of the master have often less effect upon a naturally indifferent pupil than the example of his fellows.

The other subject, somewhat allied to these questions, which was confided to the care of the Institute by the general conference of last year—that of federation—was most thoroughly considered by the committee appointed for the purpose. Their recommendations were adopted by the Council, and a series of by-laws authorising the alliance of any non-metropolitan architectural society in the United Kingdom, India, and the colonies with the Institute, under certain regulations, is the result.

#### *Municipal and Provincial Improvements.*

The new Local Government Act has not made any provision for the proper examination of technical officers employed by the urban and rural authorities. Surveyors have hitherto qualified for certain appointments by examinations held under the direction of a Board of Examiners of this Institute—a proceeding which has worked well, and been of great public service. Your Council have done their utmost, both while the Bill was under consideration in the Commons, and also in the Lords, to call the attention of those responsible for it to this defect, but without success, probably owing to the haste with which it was hurried through its later stages. It is to be hoped that if in the future the Act comes to be further amended and enlarged, as we are promised that it shall be, our recommendations will be listened to. Such a provision has been made to secure the proper qualification of medical officers to be employed by the county councils, and it is obvious that the surveyors, urban and rural, so employed should also be persons whose fitness for the very important duties they are called upon to perform has been in every case properly attested.

The Imperial Institute building is making progress under the skilful superintendence of Mr. Colcutt, and promises, when complete, to be a very imposing structure. Our late lamented President implied in his last address that, except that it were

considered that the President of the Royal Academy (our Honorary Associate) represented architecture as well as painting and sculpture (and so he does, and most ably), the representation of architecture was conspicuously absent on the Executive Council of the Imperial Institute; but I have now good hope that architecture will be represented on it, for such a representation is likely to be of much service both to our colonies and to the profession at home and abroad. Mr. l'Anson's suggestion that the Imperial Institute might fitly collect a complete record of the architectural wonders of our Indian Empire appeared to be most valuable, and I trust it will be at the right time brought before the notice of its Executive.

In this case we may congratulate ourselves on being likely to have a public building which will be fairly seen at any rate on two sides, though, had it been placed on the north side of a square instead of being set back from a road 90 feet wide, its effect would have been enormously enhanced. The idea of sacrificing anything in the way of space for the sake of architectural splendour and effect seems foreign to the English nature; at any rate, our best sites are rarely if ever preserved for our most elaborate efforts, owing, I suppose, to there being no supreme special authority to decide such questions. It does not appear to be generally appreciated that an elaborate design ought to have a southern aspect if its beauties are to be fully enjoyed, and as a building's site is almost invariably determined upon before its architect is chosen (except in the case of private dwellings), there is at present nothing for us but making the best of what are often unworthy positions. If we go abroad we at once see that things are better ordered in this respect. Look at the Palais de Justice of Brussels. Its commanding position on the crest of a hill overhanging the old town, the open spaces which surround it, its magnificent Salle des Pas-Perdus, its stately staircases in the Salle itself, and that leading up to it from the lower town, whatever may be thought of the design of the building itself, show the advantages which have been secured by allowing ample space, both within and without, for architectural display, and to what good purpose the skilful architect has turned them, internally at any rate, in securing artistic effect. It is instructive also to note that the cost of so noble a work should be defrayed by so small a country as Belgium—a cost equal, if I remember rightly, to about 1*l.* per head of the entire population.

Vienna also sets an example for imitation in this respect. The demolition of her ancient fortifications has given her a splendid opportunity for the erection of magnificent buildings on worthy sites (as we had on our Embankment), and to good purpose she appears to be putting those sites. If we examine the plan of the Parliament Houses, designed by our Royal Gold Medallist of this year, Baron von Hansen, we shall have an instance of this. There is a generous stateliness about the building which it does not often fall to the lot of an English architect to be able to achieve. Contrast this with our own Palace of Justice, jammed in on every side (for the present unoccupied ground on the west is, I believe, reserved for the building's extension). In Brussels or Vienna they would have had wider and better-lighted corridors; but these advantages would have involved extra space, and of this there was none on the restricted Law Courts' site without giving up some of the accommodation demanded. It is impossible adequately to see the building from any side. The improved approaches to it from the north have yet to be made.

On the other hand, the domestic buildings of this country are without rivals elsewhere. Compare an English country house, erected from the designs of any of our architects who have made themselves a reputation for such work, with a modern French château—even with the published ideal of Viollet-le-Duc—and the superiority of the English work is evident; and not only in sanitary appliances is this superiority apparent, but the arrangements of plan to promote comfort and the air of homeliness which pervades the vast majority of modern English houses, have, I believe, never been approached in former times or in any other country. America may be very near us in this matter. She has certainly surpassed Europe in the originality and boldness of some of her buildings for other purposes, but the English home is still unrivalled in its quiet attractions. One can hardly leave the home without a word about the garden which surrounds it, and which adds so much to its charm. If those of us who devote our attention to Domestic architecture were to make more of a study of landscape gardening than we do, I believe that there would be more complete harmony between the house and its surroundings than is now often the case; while to the architect himself there can hardly be a more delightful change of occupation than to turn from the disappointments inseparable from building operations, to the development of those surroundings in which Nature is to play her part; as those know from experience whose clients have sought their advice in the garden as well as in the house. In the *Journal of Proceedings* we have been recommended on the one hand to turn to the grand

style—that is, the formal garden of the seventeenth century ; on the other, to give a free hand to the picturesque. But what may suit one house and one site may not suit another. In my opinion, advantage would result if we cared to qualify ourselves to give an intelligent opinion on what may add so immensely to the attractions of our work as architects, or do so much to ruin its effect.

#### *City and Town Planning.*

To return from country to town. The schemes for the improvement of communication in London too often leave much to be desired. The properties adjacent to those actually interfered with by such new thoroughfares should, if possible, also be scheduled where necessary to secure eligible building sites ; and so prevent difficulties of light and air, do away with jobbing, and give the public some more adequate return for the cost of a new street. Instead of which, building plots on the streets recently made through the heart of London have been too much composed merely of frontage, with rookeries of dilapidated tenements in the rear, whose proprietors through their representatives have reaped a harvest of compensation for injured lights.

The effect of new streets upon the adjacent existing architecture ought also to be most carefully considered, and, if unsatisfactory, some means should be taken to mitigate the awkward blemishes thus occasioned. The way in which the southern end of Shaftesbury Avenue has destroyed one of the segments of Piccadilly Circus is unfortunate, however welcome the open space thus created may be in itself. The erection of a statue, which appears to have been contemplated, on the triangular island west of the avenue would do little or nothing to remedy the now somewhat unpleasant grouping of the surrounding buildings ; but three plane-trees planted at the corners of the island would, by their soft outlines, obliterate, in a measure at any rate, the architectural discord which has been created, and add a charm to a somewhat meaningless open space. They would not, of course, prevent the erection of a group of statuary or a fountain in the centre.

Members of the Institute have, from time to time, made very pertinent remarks on the subject of our unfair and oppressive law with regard to the rights which one neighbour may acquire over another's property by putting out windows overlooking the latter, and so restricting its use as a building site. This is pre-eminently a subject for the attention of the Institute ; and surely, if it were gone about in the right way and with sufficient energy, an Act might be passed removing, to a certain extent at any rate, one of the greatest sources of annoyance and expense incident to building in towns. We know that in Scotland no such vexatious restrictions exist. I believe in America there is similar freedom. In France, too, the difficulties of the building owner are as nothing compared to what they are with us, though he is subject to the very proper regulation that the extreme elevations of buildings lining streets should bear a certain proportion to the width of the street. The unreasonable enjoyment of light which a dominant owner may have been blessed with for a certain period, simply because his neighbour has delayed the exercise of his own rights during that period, should be no cause, it appears to me, why he should be left in undisturbed possession of such unreasonable enjoyment for ever, to the detriment of his neighbour and his successors. Unfortunately the length of time that the present law on the subject has run presents serious but, I trust, not insuperable difficulties in the way of an alteration for the better.

But though we may long for this, there is something to be said on the other side. As artists, we must often have to deplore the excessive height to which our buildings have been allowed to go when unrestricted by questions of light and air—not so much on their own account, perhaps, as because of their injury to neighbouring buildings. The effect of many a fair and beautifully proportioned building of modest height has been utterly destroyed by the overgrowth of some upstart by its side ; and though we may not always be able to control our clients in this respect, I feel sure that no true artist would willingly by his own work injure that of another. Nor are architects the only offenders against good taste in this respect. There are works of sculpture which, I think, are on too gigantic a scale for their surroundings. Nobody who observes these things would regret if His Majesty George IV. were not so prominent an object when seen in front of St. Martin's Church, of which it destroys the scale ; and the same may be said of other monuments in the vicinity. In contrast, I would call attention to the old statue of Charles I. and to that of General Gordon, by Mr. Thornycroft, just erected in the centre of Trafalgar Square. The figure here is but 9 feet 6 inches high, and the pedestal, the object of evident consideration on the part of the sculptor, is correspondingly modest in size. The statue does not fail to attract due attention, though it cannot be said to dwarf anything in its neighbourhood.

#### *Professional Losses.*

During the past year we have had to lament, and do still lament, the death of several influential members of this Society.

January was a fatal month. George Godwin, the founder of the bursary for the study of modern architecture, a prominent figure in the architectural world for nearly fifty years, and an active member of the Royal Commission on the Housing of the Poor, died on the 27th ; our president, Mr. P'Anson, on the 30th ; and M. Questel, our corresponding member, and the senior architect academicien of the Institut de France, on the same day. Our late President, like Street, died during his term of office. He was seventy-six, looked back upon more than half a century of practice, and was universally respected and held in honour by all who knew him.

Then there was Edmund Woodthorpe. Though by the measure of years he had attained the age of seventy-five, he was the most juvenile among us whenever he appeared. Long will his joyous tones and genial wit dwell in our memories, and make us lament the removal of so young and elastic a spirit.

Joseph Clarke, past vice-president, whose death I have also to record, was identified with the Gothic revival by his numerous churches, the active part he took in the establishment of the Architectural Museum, and the unflagging energy with which he promoted its interests.

Nor must I omit the name of Richard Popplewell Pullan from the list of our losses. He and I sat side by side as fellow-pupils of Mr. Lane of Manchester. He then showed his powers as an artist, and his great interest in ecclesiology and kindred subjects. His practice as an architect was not great, but he devoted himself with enthusiasm and success to archaeological pursuits. His works in conjunction with M. Texier on ancient remains in Asia Minor, and on Byzantine architecture, are of lasting value. We are indebted to him also for the publication of some of the drawings left by his brother-in-law, William Burges.

The Institute has also lost Mr. T. Gambier Parry, who had been an honorary member since 1865, and whose services to architecture and the subsidiary arts were of a high order. His latest literary work, entitled "The Ministry of Fine Art," and published in 1886, is a series of thoughtful essays on subjects which their author was peculiarly fitted to discuss. Another death, that of John Pennethorne, who first detected the horizontal curves of the Parthenon, and to whose memory a just tribute has been paid by Mr. Penrose, occurred in January of the current year.

Our sympathy must be offered to our Scotch brethren in the recent loss of one of their most prominent members, James Sellars, president of the Glasgow Institute of Architects. He died comparatively young, but not before having made his mark in his native city (the International Exhibition buildings being one of his latest successes). His high character and engaging kindness of manner made him hosts of friends to lament the premature shortening of a career in which he had already done so much so worthily.

#### *Individual Influence on Architecture.*

The biographies of two of our most remarkable modern architects, which have both appeared since November last, are of great interest. George Edmund Street's Life, by his son, has about it an unusual freshness and charm, arising partly from the father's marked individuality of character, and partly from the skill with which the materials for his life have been put together. In amazing power and energy, love of work, beauty of draughtsmanship, and skill as a designer, he can hardly have had his equal. His sterling honesty of purpose and kindness of nature, even if occasionally hidden behind a determined manner, endeared him to those who knew him best. He was the most thorough and consistent supporter of revived Mediæval architecture throughout his remarkable career—a career full of interest to every architect from the days of his pupilage under Carter to his burial in Westminster Abbey. His presidential address from this chair is probably the most outspoken we have ever listened to. His lectures as professor of architecture at the Royal Academy supplement his life, and should be in the hands of every student.

The other biography I would allude to is that of a very different but also very remarkable man, Henry Hobson Richardson, of Boston, U.S.A., an honorary corresponding member. Street was the king of draughtsmen, and drew every detail of his innumerable buildings himself. Richardson, on the other hand, was supposed never to have designed one of his later and more perfect buildings with his own hands, yet no architect ever put his name to structures which were more unmistakably his own creation. Street made the pointed arch the keynote of all his construction ; Richardson saw the capabilities of the round arch, and his work in great measure was based upon Romanesque, though he treated it in his own original fashion. His works are so remarkable that I feel sure you will allow me to say a little more on a subject which has for me a singular fascination.

Richardson was a student of the Ecole des Beaux-Arts. He remained in Paris six years, working as a student and draughtsman, for he had to earn a living as well as to study, and lived practically two lives in one. In those days his great ambition

was to go to Athens and Rome. He never, in fact, went to either, and, in spite of his training, never was architect less influenced by what these two centres of past art would have had to teach him. On his return to America in 1866 his first designs were in thirteenth-century Gothic, and in no way remarkable. But in 1870 he gained in competition the execution of Brattle Square Church in Boston, a building remarkable for its campanile with deep sculptured frieze, a tower so original as to be like nothing he could have seen or heard of elsewhere, though it has about it a certain Romanesque air. The neighbouring Trinity Church followed soon after, with a central tower of excellent proportions, both in itself and as part of the composition of which it was, of course, the crowning feature. In construction it is no less bold than its detail is beautiful. Its weight of 8,500 tons is supported by four granite piers with a collective area of 100 square feet. His public libraries, of which he built several, have a family likeness in their plan and style, though each proclaims its distinctive character. His Pittsburg Court House, Field's Chicago Buildings, and Cincinnati Chamber of Commerce are buildings of a monumental character, and give evidence of an original creative mind, free from prejudice and unfettered by precedent. Richardson's peculiarities may be seen in all. These peculiarities appear to be chiefly the discarding of the Orders, the Romanesque feeling, admirable planning, appearance of strength and solidity, the value put upon mere wall surface whenever attainable, the treatment of this surface by the varied coursing of the stonework, and the contrast between tooled and rough surfaces; the use of coloured materials, especially of stone of different hues; battered bases, sparing use of string-courses, the introduction of deep vousoirs, the rounding of salient angles, and a leaning to circular forms on plan. In his later work his corbels are rounded and covered with delicate incised carving instead of mouldings, and his capitals are convex rather than concave. All these peculiarities appear to be based on sound judgment, and to be excellent in every way. On the other hand, if criticism were in such a case allowable, there seems, to my eye, almost an affectation in the shortness of some of his columns, and want of height in many of his circular archways. There is something ungainly in the upper part of transomed windows being made wider than they are high. It is also to be regretted that in many of his buildings the ridge and hip tiles and gable finials appear to be so heavy as to dwarf the general effect. In 1882 Richardson visited for the first time Southern France, Northern Italy, and Northern Spain, and only then saw the best specimens of the architecture from which he drew his inspiration. The effect of this tour, though he allowed himself no time for sketching, is visible in the works he executed in the short time afterwards left him. His becoming so devoted to, and so skilful an originator in a style, the best examples of which he had not seen, is in itself extraordinary, unless, indeed, a Romanesque wave had affected the American architectural mind before his advent. He seems to have created a new-born interest in architecture in America, perhaps by doing exactly what he thought best suited to the expression of his buildings, without going out of his way to look for precedents. In consequence, his work is never commonplace. He has left behind him a school of young Americans who appear to be following his steps in developing the capabilities of Romanesque art—an art which we must bear in mind did not die of inherent weakness, but was extinguished before its time in the twelfth century by the difficulties of vaulting oblong spaces, and the consequent introduction of the pointed arch. I have, perhaps, said enough to show that Richardson's Life, by Mrs. Van Rensselaer, illustrated by photographs of his works, is worthy of earnest study.

#### *Architectural Literature.*

An appeal has just been issued by M. César Daly to his brother architects of France, England, and America, in favour of what he calls the "Hautes-Etudes." He would have those who are interested in, and gifted for the work, seek for the causes which have affected architecture in different times and places, and given it its varied outward development. He is sanguine that such search for first principles would lead to progress, and tend to check pure archaeological work on the one hand, and irrational eclecticism on the other, which he describes as the pillage, more or less skilful, of old monuments, but not the conservation of great traditions. He condemns the present fashion of following our individual tastes, each architect being a law unto himself, and laments that Duc's prize for an "Essay to determine the style and form of modern architecture" has not been properly competed for. The "Hautes-Etudes," if set about in earnest, ought to do much to remedy these and other evils so eloquently set forth in the appeal. M. Daly proposes an International Congress of Architects to be held in Paris next year during the great Centenary Exhibition, for the purpose of considering these higher questions. All must heartily wish him success in these his persistent endeavours to advance our art by a deeper and more systematic study of its principles.

Of new publications within the year I must mention Professor Hayter Lewis's "Holy Places of Jerusalem," which will appeal to various classes of readers. By his intimate acquaintance with the authors, ancient and modern, whose works bear on the subject, and by his conscientious study, on the spot, of buildings which illustrate his theories, the writer has produced a work of unusual interest.

Mr. R. Phené Spiers's book on "Architectural Drawing" has brought a valuable addition to the architect's library. His subject is handled with such care and thoroughness that draughtsmen must find in his letterpress and illustrations much to interest and instruct.

Mr. Alexander Graham and Mr. H. S. Ashbee, in their "Travels in Tunisia," describe a ruined country in lively, fascinating style. The work is replete with valuable information, not only on architectural and archaeological subjects, but on the everyday matters of life and ordinary commerce. They give also an excellent bibliography of the country they describe, and their book is a guide of great value to the traveller in search not only of general knowledge, but of a deeper acquaintance with the remains of Roman civilisation in an important part of northern Africa than falls to the lot of the ordinary tourist.

Our profession being, in an especial degree, among the fine arts, based upon the study of the past, the value of historical research respecting it, and of pictorial reproduction of the works of great masters, can hardly be overrated; and I am therefore induced to mention a large folio work\* upon which our esteemed member, Baron de Geymüller, in concert with other distinguished men, is now engaged. It is proposed to do, under his superintendence, for Tuscany what has already been done for the Renaissance works of Rome, in the illustration and analysis of great public and private buildings. Baron de Geymüller has presented to the library the first two numbers, and our *Journal of Proceedings* will, from time to time, contain detailed notices of this valuable work.

Of the numberless exhibitions of the year, that of the Arts and Crafts is one to which we may give a most cordial welcome. It brings into notice those arts to which the ordinary picture exhibition turns the cold shoulder, and which, delightful in themselves, are essential to the architect. The decorative artist and the art workman have, within the walls of this exhibition, an opportunity at length afforded them of making themselves known to a wider and appreciative public.

The important questions to which I have been alluding—the direction and design of new streets, the law of light and air, the heights of new buildings and their relation to the width of the street—are all subjects pre-eminently fit to be submitted at no distant date for the consideration of the new Council of the County of London, of which I am glad to think our distinguished Hon. Fellow, the Duke of Westminster, is to be the first Lord-Lieutenant. There are, however, other questions of like importance as far as we architects are concerned, which we can, if we choose, of our own will settle, or at least bring to such a point as will conduce to a future settlement, when our profession is perhaps in a more homogeneous condition than it is at present, and when uniformity of professional practice will be regarded as necessary to the position and welfare of the members of a liberal profession.

#### *Architectural Etiquette.*

My predecessor, in his first address to you, gentlemen, from this chair, urged us to remember that the Institute and the profession are in principle one and the same force, inseparable and indistinguishable one from the other. I entirely agree with the proposition, and in my opinion the first duty of the Institute is to guard the honour of the profession, to take care that its members do nothing derogatory to their professional character, or, at the worst, that they shall not do so with impunity. I am not now alluding to illicit or surreptitious commissions or allowances, or of the offers sometimes made of something by way of consideration for employing certain people or their wares on our clients' works. I trust that, owing to the powers vested in the Institute and the right feeling of its members, such malpractices are of the past. I mean that when any of us undertake duties of public trust, whether it be in an honorary or a paid capacity, in any office or on any council or board, we ought to scrupulously avoid using our position for any private ends or gains, whether as professional men or as individuals. In an address delivered nearly ten years ago from this chair, at the opening of the session for 1879-80, the late Mr. Whichcord referred to the Metropolitan Board of Works and the professional men who might be members of it in the following terms:—"Architects," he said, "may be elected members of that Board just as barristers, solicitors, and doctors may be so elected. It would be ridiculous to say that professional men shall not sit at that Board because they may have had a pecuniary interest in some of its building transactions. But I shall run no risk of censure

\* *Architektur der Renaissance in Toscana nach den werken der meister geordnet.*

when I say that a Fellow or an Associate of this Institute, if he be elected a member of the Metropolitan Board of Works, ought not from that moment to have any professional connection whatever with the purchase of land offered for sale or lease by the Board; nor should he be professionally engaged in the superintendence of buildings to be erected on land which is the property of ratepayers whose agent and representative he is." The late Mr. Street in 1881 repeated those words, as I have just done; and I cannot but think that the advice they offer, or the warning they convey, may be advantageously studied by all who aspire to sit on the County Councils that are about to be summoned under the provisions of the new Local Government Act. If the Institute is still to flourish—if the character of the profession is to be maintained—it must be by jealously raising the standard of conduct of the individual members rather than allowing it to be lowered through the indulgence of any good-natured laxity.

We need not despair of success in stamping out abuses if only we are convinced of the necessity of so doing, and are earnest in the endeavour. Something, at least, has been done within the last few years to render architectural competition less liable to unfairness and jobbery than before. It is now well understood that there is one man who must not under any circumstances undertake the office of architect to the building competed for, and that is the assessor. Nothing would be easier for an assessor than to play cuckoo to the poor hedge-sparrows of competitors, who are pretty much at his mercy, and nothing obviously more unfair. But such an abuse, if it has occurred, may now be considered a thing of the past.

#### *Quantities and Contracts.*

There is another point of professional practice in which we might probably see more justice done than at present. We are in the habit of regarding the bills of quantities issued to competing builders as final instruments incapable of containing error, unless the successful builder finds it out between the day on which he sends in his estimate and the day on which he signs the contract, which may be the day after. Are we in these matters as scrupulous as we ought to be that justice be done to the builder? His lot, owing to the severity of the competition to which he is generally subjected, is a sufficiently hard one without our making him practically responsible for other men's errors. Our Scotch brethren measure up the work after completion, though competed for in the ordinary way on preliminary bills of quantities. If we are not prepared for that, let us at least be willing to allow for the correction for errors in taking out the quantities, when it is obvious that omissions have been made. Some few architects are in the habit of telling their clients that they must not hold their surveyor personally responsible for the correctness of his quantities, but that he is a man of position, will do his work with the greatest care, and allow no margin for contingencies. I have rarely met with an employer who failed to see the justice and even advantage of such an arrangement. There would be obvious convenience in uniformity of usage in this matter and in other points of professional practice also: for instance, I believe great divergence of opinion exists as to whether an architect is bound to give more than one set of drawings, or of tracings of his drawings, for the use of the works. I have until lately adhered to the view that he is not, but the great facility now offered by the ferro-prussiate sun-printing and other kindred processes enabling us to reproduce any number of copies of a tracing without the possibility of error, and thus saving all trouble of examination, seems to put this question in a new light. I am of opinion that the Institute might suggest a mode by which a somewhat more generous supply of facsimiles of the contract and detail drawings might be supplied gratis to the contractor with little more expense to the architect than at present. Two things are obvious, the necessity of receiving payment from the builder for additional copies of drawings should be done away with, and uniformity of practice in this matter should be aimed at. It is known that, in France, where, owing to the great number of independent contractors employed on the same work, the reduplication of drawings is a more serious affair than with us, the architect, nevertheless, considers it part of his duty to supply them all without extra charge. The great number of drawings required by municipal and other corporate authorities is also a considerable tax upon us or our clients, and it would be well if such bodies could be persuaded to take mounted sun copies instead of tracings on cloth.

Then there is the desirability of a more general application of the arbitration clauses (Nos. 20 and 21) of the heads of conditions of building contracts sanctioned by the Institute and agreed to with the representative builders of the country. I know that there are architects who put in the building contracts they make, as the agents of their employer, a clause to the effect that the architect is to be sole judge, arbitrator, or umpire in any dispute which may arise between the two parties—the architect, as the agent of his employer, being one

of the said parties; and I know that there are builders—sharp, shrewd, and alive, nevertheless, to their own interests—who are willing to put their names to such documents; but it is a practice of doubtful expediency, and I urge upon the young men who are here to-night, before they impose arbitrary conditions of the kind, to reflect that no man can be fairly or safely judge and party in the same case.

#### *Architectural Study.*

We have heard something lately of the conflicting terms "professional man" and "artist" as applied to the architect. Now in my opinion the true architect is both. The higher and more systematic education, which we are hoping for and getting, will train us in the efficient and easy practice of our profession—a profession which is open to all men of education, intelligence, and industry, and one in which the greatest successes will attend those to whom further an artistic perception has been given, and in whom it has been carefully cultivated. In speaking of an architect as an artist I do not mean that he is to be a clever draughtsman merely—far from it. A man may be the most exquisite of draughtsmen, and yet be entirely deficient in the critical sense of what it is that makes a work of architecture beautiful. His works then will not be beautiful, and, so far as his architecture is concerned, he will not be an artist. While not neglecting to cultivate our powers of delineation, we might perhaps do more to make those powers of use to us than many of us do at present. If, for instance, instead of sketching ancient examples so much, we were content to do half as much in this way, and afterwards were to endeavour to reproduce our sketches and scale drawings from memory, we should accomplish two things—marvellously sharpen our observing powers, and greatly increase our facility in design. We should make the building we are studying our own; it would be in our heads and not merely in our sketch-books. Our memory drawings would be tinged with our own individuality and shortcomings, which it would be well to correct by after-reference to our original drawings, or, better still, to the building itself if accessible. And, further, if time could be spared to analyse the sources of our satisfaction in the object of our study, to take notes of its excellencies or defects of plan, construction, and detail, that time would not be lost, though we might have less to show to admiring friends, fewer trophies to hang on these walls as evidence of our industry and powers of draughtsmanship on our return from a tour, the result of victory in some Institute prize competition. I wish it were possible for the Institute to discover not merely what our prize-holders draw during their tours, but what they have learnt, what they have assimilated, what has become part of themselves. I believe the study of one excellent example—say a church—if thoroughly done, would do more to make an architect than rushing, sketch-book in hand, through half the cities of the world, even if years were spent in this sort of travel. I speak not as one who has lately attained to any sort of excellence in this way, though I begin to see clearly what I have lost by not practising it.

#### *Architecture in the Future.*

It is to our young architects that we look for triumphs in the future. We rejoice in the prosperity and vitality of the Architectural Association, and make its members again welcome to the use of this room for their Friday evening meetings. The desirability of establishing a kind of "common room," in which the young and old of our profession may meet and exchange ideas, was strongly urged by Mr. Appleton in his recent address. I can only repeat that in this, as in all other things, the Institute will help the Association as far as lies in its power. The annual prizes which the Institute has to bestow, through the munificence of its members, are largely competed for, as they should be, by members of the Association. There is certainly a most encouraging excellence in the draughtsmanship of many of the designs sent in, and I think also in design itself there is to be noted an advance on former years. When the prizes were distributed last, it was remarked how few of those we wished thus to honour were present to receive their rewards. This was to be regretted, as it is always a pleasure to those who meet here to see, and it may be make the acquaintance of, their younger brethren who have so distinguished themselves. At the Royal Academy, the prizes won are not given at all unless the victors present themselves on the occasion appointed for their distribution. On behalf of competitors for travelling studentships, I would express the hope that means may be devised to reduce the length of time during which it is compulsory for the student to travel if the sum awarded fall very far short of the expenses likely to be incurred. The Soane 50% studentship, for instance, involves a six months' tour. More may now be done in a shorter time than formerly, but at a proportionately greater outlay, and the inadequacy of the sum to cover the expenses of so long a period of travel no doubt prevents many, who would otherwise be inclined to contest the prize, from entering the lists.

Our reverence for the excellence of our forefathers' work,

and our delight in what has been superadded to that excellence by the finger of Time, making it yet more lovely, is a characteristic of our own day, and will induce us to deal tenderly with old work when it comes under our care. But there are now, unfortunately, not many buildings left upon which the architect and workman can exercise their forbearance and show their reverence for the "charm of mutilation and the fascination of decay." It may be proper to enlarge, add to, or even pull down old work for new, but surely never to endeavour to make old work look like new. The mischief which has been done in this way in England is immense, but nothing to what has been endured in France and Italy. Now a better state of feeling on the subject of restoration is gradually extending to the latter country. If they appear to agree with us in theory, however, they do not yet altogether in practice. When in Venice last spring I looked out in vain for an old friend, the Fondaco dei Turchi, by the Rialto. It had been rebuilt, and failed altogether to recall the impression of the old building which it is supposed to reproduce. Occasionally we may see our way to replace old work when research has made clear to us what it was originally, as Scott did at St. David's, and as Mr. Pearson is doing at Westminster Hall. Such cases must, however, be exceptional. It is certain that the past did not respect its own past as we do ours, and our practice, commendable as I think it, has no doubt its dangers. If we are for ever dwelling on the past we shall not be self-reliant; and if not self-reliant we shall never be bold originating architects. The Greeks spent their powers as artists in perfecting their own work, not in resuscitating a dead style; our Mediæval brethren theirs in the marvellous development of their own phase of architecture; the artists of the Renaissance, in spite of their name, were likewise originators. It has been left to us to copy, or, as M. Daly puts it, "to pillage ancient monuments"—not, like the church-builders of Byzantium and Venice, by boldly robbing other buildings to create fresh architectural marvels out of the material thus provided, but by reproducing old forms, with more or less ability, but also with more or less inappropriateness. Does it not behove us occasionally to consider this question seriously, and to ask ourselves to what good end this eternal copying and adaptation is to lead? We see that in America they are shaking themselves free from tradition. No doubt it is comparatively easy for them to do so; but are we to allow them to monopolise the guidance of common sense in architecture? May we not also make greater efforts than we have hitherto done to express the purpose of our works in a language of our own; to clothe our buildings, not in the cast-off garments of bygone ages, but in materials cut out and fashioned to suit ourselves and our own needs? We may love and reverence the past as archaeologists, but as architects let us not forget that archaeology is the bane of living progressive architecture, and that if our art is ever again to evoke popular enthusiasm, it must do so by embodying the thoughts, the aspirations, and the genius of the living people for whom we build.

I fear I have already tried your patience, so I will detain you no longer, but conclude these somewhat discursive remarks by expressing the hope that we may all, both in our private practice and as members of this body corporate, do our utmost to give our art a firmer hold on public admiration and attention, and our profession respected by all with whom we come in contact, so that every member of the Royal Institute of British Architects, whether his work be lovely or not, may at any rate show in his life the things that are honest and of good report.

Mr. EWAN CHRISTIAN observed that he was sorry the task, or he should say, the pleasure, had not fallen to abler hands, but he rose to ask their hearty thanks for the President for the interesting and practical address with which he had favoured them. The President had traversed a wide field, and he did not intend to follow him through the whole of his wanderings. The President had congratulated them on the completion of a work commenced under his (Mr. Christian's) presidency, namely, the revision of their Charter and the passing of the by-laws which accompanied it. In a short time he hoped the work would be consummated. That was a matter to rejoice over, for it had been a source of trouble and anxiety to complete it properly. He and most of them must agree with the President that they wanted education and not registration, and that candidates should so prepare that they might pass the examinations creditably and without cramming. They wanted highly educated men as members of their body, and they would have many of those as time went on. The President had spoken strongly, and rightly so, on the matter of laying out our cities. He had very properly commented on the destruction of Nash's lines in the laying out of Regent Street. Nash might not have been in the front rank as an architect, but he certainly had a genius for laying out cities. The lines of Regent's Park and Regent Street were such as should be recognised in these days as most able works. The Quadrant had been tampered with in the first place, but in destroying

the Circus a great evil had been done. Surely, he said, something might have been done to prevent the destruction of the excellent arrangement laid out by Nash. That, he feared, was hopelessly lost and not now to be remedied. On the subject of what had been achieved in Continental cities, Mr. Christian remarked that we had not space here to do things on such magnificent lines. What they could do they would, to prevent light and air being shut out of their streets. He could not but rejoice that the scheme for the War and Admiralty Offices was knocked on the head, for now, as long as he lived, he would see the sky over the top of Whitehall. The Law Courts had been referred to in the address. That building had been most cruelly treated. Mr. Street's fine design had been absolutely ruined because the authorities would not give him a few more feet of ground—ground now utterly wasted, and being laid down in grass. It would have made a totally different building of it, and would have given space for the corridors; and they it would have a magnificent building for all time. There had been absurd remarks made in some of the public papers of late, but architects knew how shamefully Mr. Street had been cramped. Had there at that time been proper care exercised in the laying out of public places and buildings, things would have been different. In regard of country buildings, few persons, Mr. Christian said, knew what an immense work had been done in the construction of private residences that were dotted about the country. Almost everywhere new buildings had arisen, so that the Victorian era had been more prolific in the erection of interesting buildings than even the Elizabethan age. He thoroughly agreed with the President how important it was that an architect should be capable of designing not only the material building, but also be able to fit it into the surroundings with perfect beauty. Those who had visited Castle Howard, in Yorkshire, would have seen that the architect was a consummate artist, as well as architect, in stone and mortar. Nothing more excellent in the laying out of the place and the surroundings could, he considered, be seen anywhere. For one who had the opportunity of building a country house there was nothing more delightful than thinking out the scheme of the surroundings and beautiful gardens. Unless they could thus see it all from the commencement the work was likely to be a failure. The biography of Mr. Street was a book that should be in the hands of every student. It was hoped that there would soon be another edition, which would combine with the letterpress a few examples of the wonderful sketches made by Mr. Street. Along with Mr. Pearson he had travelled in Savoy with Mr. Street just two months before his death. Arriving at the Lac de Bourget, Mr. Street had immediately seized on a fine doorway on the south side of the church, and in a short time had made complete drawings in his sketch-book, with every detail that was necessary for a workman to carry it out. Mr. Christian next spoke of American architecture. The influences at work there were different to those here. American architects were hampered by the unfortunate circumstance, as he thought, that there was nothing firm in the way of administration. Every four years there was an upset; architects were changed as well as other individuals, and architecture showed signs of the deleterious effects of that system. He was amazed when he saw the wonderful tower of Trinity Church at Boston. They never got to such dimensions in England as were illustrated in that tower. It was one of the most beautiful examples of a tower that he had ever seen. America was in an interesting condition as to art. It was a giant at work, but it hardly knew how to use its tools. The result would be some day a grand one indeed. The death of the great architect Richardson was to his mind a national misfortune to America. It took a long time to produce an artist like that man. They could not expect to see another Richardson, though they might see many of his pupils. Mr. Christian concluded by saying he fully shared in the President's horror at the terrible profanation of that interesting building the Fondaco dei Turchi, all that had been beautiful about it having been destroyed.

Mr. FLOCKTON said he had been both honoured and surprised by the request to second the proposal to return thanks to their President. His notions of modesty would not permit him to make a speech were he able at so short a notice. Time and ability had been devoted to the address to which they had listened. That time and trouble were required he was able to affirm, having in a very humble way had to prepare a presidential address himself; also anxiety that one might say everything one should say, and say nothing one would wish not to have said; and also anxiety to interest the audience rather than send them to sleep. The President had fulfilled all those conditions most thoroughly.

The vote of thanks was carried by acclamation.

The PRESIDENT in replying said he had been particularly gratified in hearing from Mr. Christian's lips how he supplemented his remarks on the Law Courts and their late lamented president, Mr. Street.

The meeting then adjourned.

15 Park Row, Leeds.

## NOTES AND COMMENTS.

THE exhibition of the works sent to Paris by the students in residence in the Villa Medici, Rome, was opened lately in the Ecole des Beaux-Arts. The most remarkable of the architectural works is M. REDON'S restoration of the ruins of Baalbec. Among the paintings may be noted a decorative composition by M. BASCHET, M. LEBAYLE'S *Lazarus at the Door of Dives*, and M. PINTAS *Tobias*. In sculpture, M. GARDET'S *Archer*, the *Cupid and Psyche* of M. CAPALLERO, and the *Holophernus* of M. LOMBARD attracted attention.

FEW visitors who enter the church of the Sorbonne, in Paris, could believe that at one time it contained statues of the twelve apostles. They were transported to his military school of Saint Cyr by NAPOLEON I., and placed in the chapel of that institution. The Sorbonne is now about to enter on a new lease of life, and, although the church may not be much utilised, there is a desire to bring it more near its original condition. Application was made to the Minister of War and he agreed to return the statues. The tomb of RICHELIEU (it was deprived of the remains of the Cardinal during the Revolution) will once more have the companions which were removed eighty years ago.

NICHES were formed in the new Luxembourg Gallery for the reception of busts of artists. The authorities have selected the subjects. They are as follows:—HOUDON (1741-1828), the sculptor; DAVID (1748-1825), the painter of Greek and Roman scenes; Baron GROS (1771-1835), painter of Napoleonic and Royalist scenes; RUDE (1784-1856), the sculptor of the vigorous *Departure of the Volunteers*, or *La Marseillaise*, on the Arc d'Etoile; PRUDHON (1760-1823), painter of religious and idyllic subjects, and draughtsman; DAVID D'ANGERS (1789-1856), sculptor and Republican enthusiast; INGRES (1781-1867), champion of the "Classicists" in painting; PRADIER (1792-1852), sculptor of *Sappho*, *Phryne*, *Venus disarming Cupid*, &c.; DELACROIX (1799-1863), champion of the Romanticists in painting; BARYE, sculptor of animals, one of the great artists of the age, who was compelled to model paper-weights and insignificant works; THEODORE ROUSSEAU, the landscapist, who was called "le premier apôtre de la vérité dans le paysage"; and MILLET, who transformed the sordidness of French agricultural life into beauty. According to the Administration of the Beaux-Arts as now constituted, the foregoing men are to be considered the representative artists of France during the century.

THE difficulties which attended the project for the utilisation of the Castle of Norwich as a museum seem to be an end. At present there is a capital museum in the city, but there is little in it, except stuffed birds and geological specimens. An objection was wisely raised that it would be vandalism if the walls were covered with glass cases. It is now proposed that the birds shall be placed in an exterior corridor, and the ground floor of the keep be occupied with archæological objects, fossils, &c. The alteration of the castle—including a roof over it—will cost 10,756*l.*, of which four-fifths are collected. The items of Mr. BOARDMAN'S estimate are as follows:—Keep, 3,711*l.*; Bigod's Tower, 100*l.*; committee-room, with additional width of corridor attaching, 800*l.*; adapting three blocks and connecting them, 2,415*l.*; heating, gas, and drainage, 800*l.*; incidental expenses, including lavatories, &c., 530*l.*; new wall-cases, 1,880*l.*; architect's commission, 515*l.*; total, 10,756*l.* A joint committee will be appointed for the new museum, representing the Corporation, the existing museum, and Lord WALSINGHAM'S Committee.

It is supposed that HANDI-BEY, the director of the Ottoman Museum at Constantinople, who is now journeying in the East, will stop at Smyrna in order to superintend

the excavations which are to be undertaken in the search for the *Apollo* of PRAXITELES. A peasant has, it appears, discovered the head and arms, which are in the noblest style of art. They were not broken off the figure, as the head and arms were joined to the trunk in an ingenious manner.

AMONG the works which established the reputation of HANS HOLBEIN the Younger was a series of frescoes illustrative of the history of the HERSTENSTEINS, which he painted on the walls of the mansion of the family in Lucerne. They were commissioned by JACOB DE HERSTENSTEIN, a patrician of the city, and who was a friend to the painter. In 1826 the old house was restored, and in the course of the transformation HOLBEIN'S frescoes were cleared away. Fortunately the principal scenes were copied with exactitude by SCHWEGLER, and they are now about to be reproduced by a publisher of Lucerne. The plates will be accompanied by a history of the HERSTENSTEIN family by M. DE LIEBENAU, the historian.

IT would appear from a report by M. LAMOUREUX that Paris contains too many houses for the population, a circumstance which is evident to any one who perambulates the new quarters of the city. Between 1876 and 1881 the population was increased by about 300,000, and speculators were warranted in believing that it was safe to provide for a continuous growth in a similar proportion. But in the five years which followed—1881 to 1886—the increase was only one-fourth, or 75,000. What was the consequence? In 1885 there were 17,000 logements or tenants' dwellings unoccupied, representing an annual value of 4,962,000 francs; and this year the vacant dwellings are returned as 28,837, of which the value is 7,335,000 francs. It is believed that the unoccupied dwellings are mainly those which were intended for people who could not pay high rents, but who now prefer to live in one of the suburban districts. The growth of places like Asnières, which are inhabited by men and women who work every day in Paris, is a sign of the change in French manners which a few years ago would have seemed to be an impossibility.

THE authorities of the Paris Exhibition have sanctioned a credit of 250,000 francs for forming luminous fountains like those which were introduced at South Kensington. The French people are fond of fireworks, and as the English fountains will give plenty of colour and light, they are intended to serve instead of pyrotechnic displays. Another element of the picturesque will be found in the Turkish, Moorish, Indian, Roumanian, and Javanian cafés, the Franco-Annamite restaurant, the Dutch bakery, the Swedish beer-house, and the English dairy, which are also to find a place within the boundaries of the Exhibition. The Chambers of Commerce and the Maritime Ports are to have a pavilion, which is to cost 2,000*l.* The city of Paris has shown the right spirit in allowing the demolition of the two pavilions which were erected in order to display evidence of the works undertaken by the municipality. They were supposed to interfere with the general effect, and the sites will be converted into gardens.

MR. L. H. LEFÈVRE has just brought out a fine original etching of the Tower of London by Mr. LAURENCE B. PHILLIPS. The subject is one of the most picturesque and interesting in London, and Mr. PHILLIPS has represented it from a point of view which allows full expression of the building and its surroundings. The etching is effective in treatment, and it is evident that the artist is able to appreciate and to render what remains of ancient architecture in London. It is to be desired that he may be allowed many opportunities for producing similar works. The publication of the etching by Mr. LEFÈVRE is a guarantee of its quality.

ARCHITECTURAL ILLUSTRATION SOCIETY.  
SECOND SERIES.

NOS. 37, 38, 39.—SKETCHES FROM NISMES. [A. NEEDHAM WILSON.]

MISSION-ROOM, LEEDS.

SCHOOLS OF ST. ANNE, HAUGHTON, NEAR MANCHESTER.

THE above schools, which we illustrate in the present issue of this journal, have been erected and furnished throughout at the sole expense of Mr. J. W. SIDEBOTHAM, M.P., and Mr. E. J. SIDEBOTHAM, M.A. The schools are another step towards the completion of a scheme which the late Mr. JOSEPH SIDEBOTHAM, of Bowdon, had intended carrying out for the benefit of this district. Accommodation is provided for 500 scholars. The buildings are erected of grey bricks with red dressings; the roofs are covered with Ruabon tiles. Ornamental terra-cotta panels have been introduced on the three principal elevations. In the centre of front elevation is a specially designed mosaic panel, representing St. ANNE teaching the VIRGIN MARY. The turrets and dormers are of oak, relieved by filling-in of KEEN'S cement. The windows have varied designs of lead lights in the upper portions. Master's and mistress's rooms are provided over the children's lavatories. The whole of the buildings are heated by hot water, in addition to having open fire-grates. The three essentials, efficient heating, lighting, and ventilation, have all been obtained in the most approved manner. The furniture and fittings in the various rooms are of the best description obtainable, and are in keeping with the educational requirements of the present day. The work has been carried out very satisfactorily by Mr. JOSEPH CLAYTON, builder, of Denton, from the designs and under the superintendence of Messrs. STONES, GRADWELL & GRIMSHAW, architects, Commercial Chambers, Church Street, Accrington.

## THE ARCHITECTURAL ASSOCIATION.

THE second ordinary meeting of the Association was held on Friday evening, Mr. H. D. Appleton, F.R.I.B.A., president, in the chair.

The following gentlemen were elected members:—Messrs. J. A. Waddington, E. O. Warne, S. P. Davis, J. B. Tansley, E. C. Finch, W. L. T. Brown, A. J. Hardwick, A. Spiers, A. J. Roddis, F. Rhoades, W. Langbein, A. Cox, C. Roche, A. G. Salmon, A. E. Watson, H. P. Adams, A. P. Crabb, R. N. Sinclair, T. H. Bishop, S. Howard, G. P. Armstrong, M. Price, A. Hogwood, E. R. Cook, P. S. Worthington, G. E. S. Stratfield, H. E. Kirby, J. C. Watt, W. W. S. Smith, J. Hunt, J. H. Richardson, H. L. Goddard, H. F. Mence, G. Kenyon, D. B. Niven, A. H. Crawford, A. Wollheim, J. H. S. Fane, A. A. Abrahams, E. C. Frere, J. A. Pywell, F. E. Williams, F. J. Potter, J. Murray, J. Steuart, J. R. Stark, F. Cook, J. W. Wyles, A. Whitcombe, E. A. Whipham, W. C. Ashworth, H. E. Elkins, W. E. Holland, G. G. Lynes, J. W. Hall, G. P. Pratt, R. W. Gibbon, H. Story, F. J. Slater, C. G. D. Innes, E. J. Wallis, H. G. Leslie, H. C. Mann, C. Evans, W. A. Hughes, and W. Palotta.

Mr. T. E. PRYCE, hon. secretary, stated that any members so desirous could attend the lectures given in connection with the Arts and Crafts Exhibition on the lower scale of fees. They should send in their names to the hon. secretaries as early as possible.

The PRESIDENT said the first meeting of the Elementary Class of Design would be held on Friday, the 9th inst. Mr. Gardner intended to give limelight illustrations of Early English architecture of the thirteenth century in connection with Mr. Mitchell's lectures. Independently of members of the class, any member of the Association could attend that night.

Mr. J. A. GOTCH, F.R.I.B.A., then read a paper entitled "Elizabeth and Victoria."

A discussion followed the reading of the paper, in which Messrs. Kershaw, Shuffrey, and Brodie took part. On the motion of Mr. Hooper, seconded by Mr. Cresswell, a vote of thanks was passed to Mr. Gotch, and the meeting separated.

A report of the paper and discussion is postponed till next week.

## THE INSTITUTE BY-LAWS.

AT the meeting of the Institute of Architects on Monday night, Mr. MacVicar Anderson, honorary secretary, said it would be recollected that at the special meeting held last May, it was decided that the new by-laws should be submitted to the Lords of the Privy Council with as little delay as possible. Mr. Markby, honorary solicitor to the Institute, had forwarded the draft. A reply was received, dated June 30, acknowledging the receipt of Mr. Markby's letter of May 27, stating with respect to the proposed by-laws, their lordships were advised that two points in the by-laws were defective:—1st. That no provision was made for the examination of Associates in accordance with clause 4 of the Charter of 1887, nor was the passing of such examination required by any of the by-laws then put before the Privy Council.

2nd. That by clause 65 of the by-laws, the conditions of competition for prizes, &c., was left to be defined by the Council of the Royal Institute, whereas clause 34 of the Charter of 1887, subsections (a) and (g), clearly required those matters to be dealt with in the by-laws, and the Lord President was advised that the by-laws ought not to be approved until supplemented by others to supply the deficiencies.

In acknowledging the above, Mr. Markby, in a letter dated July 6, pointed out, on the part of the Council of the Institute, that sections 3 and 4 of the Charter provided that persons desirous of being admitted as Associates and Fellows as from the date of the Charter should, after the expiration of five years from the date of the Charter, pass certain examinations, and that it had not been thought necessary to do more than provide for the appointment of examiners. In deference to the views expressed by the Privy Council, clause 2 of the by-laws had been amended by a condition that a candidate should declare that he had passed the examination required under the Charter, and an addition had been made to clause 41, binding the Council annually to appoint a Board of Examiners in Architecture to conduct the examinations for candidates for admission. With reference to clause 65, it was impossible to describe in detail the precise terms of any competition which naturally varied from year to year, and a new clause had been substituted. This, with the programmes issued from time to time, it was trusted would be a sufficient compliance with clause 34, subsection (g), of the Charter.

A reply to this was dated August 16, stating that the amended draft by-laws did not sufficiently meet the objections. As to the admission of Associates, the by-laws should define—at any rate, by general description—the character of the examination which Associates have to pass, and as to the terms and conditions for prizes, &c., the by-laws should embody such of them as do not necessarily usually vary from year to year.

Mr. Anderson then stated that a draft of amended by-laws had been prepared. It was in the hands of Mr. Markby, and would be submitted to the Lords of the Privy Council, and they hoped would soon be passed.

EDINBURGH ARCHITECTURAL  
ASSOCIATION.

AT the first meeting for the session of this Association, the president, Professor G. Baldwin Brown, delivered the opening address, taking as his subject "Some Aspects of the Work of an Architectural Association." After referring to the constitution of the Association, he asked what it could do for the benefit of the various classes of members composing it? The architectural hall should, he said, be made, first, a pledge of the solidarity of the architectural profession; secondly, a place of instruction, and still better of stimulus, for the younger members; thirdly, a centre of artistic influence that might affect the public at large. The architect, often to his sorrow, had to deal not only with artistic matters, but with complicated matters of business; he had to avoid the danger of sinking the artist in the man of affairs. The Muses, if the nineteenth century had not driven them away, should be appointed doorkeepers of the architectural hall, and should suffer no business cares, no sense of professional rivalry to follow those who entered to share in the work of the Association. On the important questions of more formal union among Scottish architects, on architectural federation, and the like, it became a layman to speak with reserve, but it was not satisfactory that there should be no body constituted for Scotland in general to represent architecture in questions such as those of professional practice, which might from time to time arise. He desired to speak with all loyalty of the Institute in London—an Institute, it must be remembered, of British architects—and a good solution might be found through some process of affiliation. In any case, they should strive for more solidarity among the

members of the profession in Scotland. In the country generally there seemed too many local jealousies, too little united effort. What was the use of a lively national sentiment if it did not result in hearty common action for the general good? The Association this year was doing something towards this end by interchange of papers with other Scottish societies, meetings in common, and the like. With regard to the educational work of the Association, there were the work-classes, which had been carried on since 1883. It was proposed now to endeavour to systematise the classes so as to make them a fit preparation for the examination of the R.I.B.A. The great difficulty was the want of any endowment. There was a good work being done that might be greatly extended if a little help was afforded. Edinburgh was famous as an educational centre, but it would be a great advantage if some benevolent despot could lay hands on all the educational apparatus of the city, and redistribute the endowments and the work so as to avoid the overlapping and rivalry which were now so prevalent. Then, again, more united effort, less jealousy and narrowness were needed. But the younger members of the Association might usefully start some educational work of their own. Why should not a club or society for design and decoration be formed? It would need a name and a sort of patron saint, as St. Luke was patron saint of the artistic guilds of the Middle Ages. What name could be better than that of Robert Adam, who was as great in ornamental design as in monumental architecture. After sketching the possible work of such a society, the President concluded by reminding the younger members that though they were practical students and not dilettanti, they must remember that the dilettante had something to teach them. He dealt with art because he took a pleasure in so doing, and all artistic work should be done in the spirit of enjoyment.

#### SHEFFIELD SOCIETY OF ARCHITECTS.

THE opening meeting of the Sheffield Society of Architects and Surveyors was held on Tuesday in last week, when Mr. Flockton, the president, delivered an address.

He stated that the full attendance of members at the opening of the second session of the Society showed no falling off in zeal and energy, and augured well for the future. The first session had been a success, the sound policy of "walking before running" had answered in this as in other undertakings, and good work had been done towards the objects specified in their rules—professional advancement and the promotion of professional culture. Valuable papers by Mr. J. W. Connon, of Leeds, on "The Legal Registration of Architects," and by Mr. J. Murgatroyd, of Manchester, on "Association and Federation," had been read and carefully discussed; and the action taken by the Society *re* the Bill introduced in Parliament for the legal Registration of Architects had a direct and important bearing on it. There had been a difference of opinion amongst them on the merits and details of the Bill and the mode of its promotion; but it was unanimously resolved, after final consideration, that legal registration of the profession was desirable. The acceptance of the invitation of the R.I.B.A., for the alliance of their Society with the Institute, was matter for congratulation, showing the desire of the Institute to establish a broader basis for a cordial, intimate, and practicable union with provincial societies than had hitherto existed. In his own case the modified form of declaration had removed all difficulty, and he had at once applied for and had the honour of election as a Fellow confirmed.

The courteous action of the Improvement Committee of the Town Council of Sheffield, in affording their Society an opportunity of carefully discussing the proposed new by-laws for new streets and buildings in the borough of Sheffield, and the manner in which their suggestion, given after much attention had been devoted to the matter, had been received, and especially the request that the Society should communicate with the Local Government Board, were proofs that the Society was making its influence felt.

He had been asked to accompany the chairman of the Sheffield Highway Committee, with the town clerk and their member, Mr. W. C. Fenton, to the office of the Local Government Board in London to further discuss the by-laws. Finally, the draft by-laws had been referred back to the committee for further revision; and this had since been done, the alterations referring especially to open spaces to be left in front and rear of new property in central town sites.

In the advancement of professional education, especially amongst the junior members, valuable papers had been contributed by Mr. C. Hadfield, on "The Position and Attainments of the English Architect"; by Professor T. Roger Smith, on "Architectural Education"; and by Mr. J. D. Sedding, on "English Architecture." In the coming session papers on technical subjects would be read:—In November, on "A Proposed Improvement in Theatre Planning," by Mr. E. J. Tarver;

in December, by Mr. H. W. Brewer, on "Some of the Smaller Municipal Buildings of Germany"; in January, by Mr. J. McNery, on "Estimating"; in March, by Mr. W. Emden, on "Theatres"; and probably by Mr. H. Stannus and others. On the whole the prospects of their Society were cheering; and if they all pulled together, and did not allow interest and exertion to relax, there was no doubt of its capacity for doing useful work, and of the prospect of its becoming a permanent and very beneficial institution; and he was sure he should not appeal to them in vain to keep up interest in the work they had so well begun.

He proceeded to review the state of architectural practice in Sheffield half a century ago—about the time of his entering the profession. In those days work had to be carried on with few of the aids now available. The Royal Institute of British Architects had held its first meeting the previous year. There were no professional journals with their valuable illustrations and information, no photography; lithography was in its infancy. Facilities for study were limited, and travelling far in search of existing buildings difficult and costly. Nowadays all this was changed. But young men must remember that the men who preceded them were determined to acquire knowledge in spite of every difficulty; and if they wished to succeed nowadays they must avail themselves of every opportunity of acquiring and storing information, and make themselves competent architects ready to seize on their opportunity as it occurred. Their honorary secretary himself had got together a few drawings of architectural work in Sheffield, from about the years 1831 to 1847, which hung on the walls. They included drawings by his father, the late Wm. Flockton, the late M. E. Hadfield, and the late J. G. Weightman, and also some of his own work. Speaking of the changes in architectural fashion, he observed that the so-called fashionable Queen Anne style, which had sprung up of late years, however beautiful and picturesque where properly treated, was in indifferent hands likely to degenerate into trumpery and commonplace work.

On the motion of the vice-president, Mr. F. Fowler, a hearty vote of thanks was awarded to the President for his address.

#### THE RHIND LECTURES.

THE subject of the concluding lecture of the present course of Rhind lectures was "The Culture and Civilisation of the Early Lake-dwellers of Europe," and Dr. Munro summed up the conclusions to be derived from the preceding lectures of the course. The relics found in the lake-dwellings furnished the materials for reconstructing the history of the people who inhabited them, and Dr. Munro went on to show in this way that the earliest lake-dwellers of the Stone Age knew the arts of spinning and weaving, cultivated the cereals, had stocks of domestic cattle, paid not a little attention to ornament, and, in fact, were in possession of all the elements of a high state of civilisation. He showed how the Stone Age, after a period of transition, passed into the Bronze Age, which was characterised by a higher degree of refinement and greater knowledge of the arts of civilisation, and he discussed from the osteological remains of the lake-dwellers the probability of the Bronze Age having been brought about by the advent of a new race of settlers. Then he discussed the characteristics of the Iron Age, and from its sudden appearance in Switzerland, and the perfection to which the manufacture of iron appeared to have all at once attained, he showed how it indicated a new race of people, who had conquered the old lake-dwellers and brought about the downfall of their civilisation. He discussed the question who these new comers were, coming to the conclusion that they were a branch of the original Celts of Europe; and, finally, he dealt with the original settlement of the lake-dwellers in Europe, indicating from the distribution of remains the direction in which they had spread themselves over the face of the Continent. At the close, on the motion of Dr. Anderson, Dr. Munro was heartily thanked for his lectures.

#### THE LINE OF FRONTAGE.

ON Friday, in the Queen's Bench Division, an appeal was heard against an order of the magistrate at Wandsworth directing the demolition of a house, No. 149 Sugden Road, Clapham Common, under section 75 of the Metropolitan Management Act, 25 and 26 Vic., cap. 102, enacting that no building should, without the written consent of the Metropolitan Board of Works, be erected beyond the general line of building in the "street, place, or row" of houses; and that any building erected without such consent might be demolished. Sugden Street and Marney Street had been recently laid out on a newly-formed building estate, parallel to each other, and at right angles to Clapham Road. The superintending architect

certified, on February 13, 1888, as to what was the general line of building in Clapham Road, at which date the house now under discussion was not as yet erected. As now erected it was in line with the rest of the row in Sugden Street and faced that street, and had no means of access except from that street, but projected beyond the line in Clapham Road. The general line of building, as certified, in Clapham Road was at a greater distance than 50 feet from that road; the house in question was less than 50 feet from that road. On April 13, after hearing the complaint of the Board of Works, the magistrate ordered the house to be demolished, as being a building in the "street, place, or row" of houses in the road, and projecting beyond the general line of building in the road, and within 50 feet of the highway. Counsel relied in support of his contention upon the case of *Barlow and Another v. The Vestry of Kensington* (11, App. Cases H.L., 257). In that case the appellant (against an order directing the demolition by the vestry of his house) lived in a house at the corner of the Kensington Road and a new street, called De Vere Gardens. The site of the house, abutting on the eastern side of De Vere Gardens, projected beyond a row of houses on that side of the gardens. The superintending architect to the Metropolitan Board of Works certified that the main front of that row of houses in De Vere Gardens was the general line of building in the gardens, but did not decide that that was the general line of buildings either of the row or street in which appellant's house was situate. The House of Lords, reversing the decision of the Court of Appeal, held that no offence under section 75 had been committed, and that there was no jurisdiction for the magistrate's order directing the demolition.

Lord Coleridge said:—If appellant's contention was correct, immediate legislation would indeed be at once necessary. Here the architect had certified to the building line; this building had been found to be within the building line so ascertained. It was not denied that this building was one which, if it faced Clapham Road, would be in Clapham Road; but it was urged that it was, facing as it did to Sugden Road, not in Clapham Road but in Sugden Road; and therefore that the building was not an encroachment such as could be ordered to be removed. So to hold would practically nullify and render nugatory all the provisions of legislation upon the matter. It was found as a fact here that the building was within the building line and also that it was situate in Clapham Road; hence it was within the prohibition of section 75. On an expression in section 13 it was sought to found an argument, which was too subtle, that there was a difference between a finding that "the site of a building" was in such and such a street and a finding that a "building" was in such and such a street. This decision in no way clashed with the recent decision of the House of Lords in the *Kensington case*, "*Barlow v. The Vestry of Kensington*," by which, even if they were disposed to differ, this Court was bound, and with which he entirely and respectfully concurred. It seemed to be a decision not only sensible but obviously sound. There it was held, as might have been expected, that the house alleged to encroach on the line of De Vere Gardens was not in De Vere Gardens, nor subject to observe the general line of buildings in De Vere Gardens; and, in consequence, that no offence had been committed under section 75 by the building of the house, and that there was therefore no jurisdiction for a magistrate's order under that section directing the demolition of the projecting part. The present case differed widely from that. The architect's certificate was here distinct and final, as laid down in "*Spackman v. Plumstead Board of Works*" (10, App. Cases, 229), and the magistrate's order, based upon that certificate, unquestionably right. The appeal must therefore be dismissed with costs.

### THE STUDY OF ART.

THE third annual exhibition of the Southampton Art Society was opened last week.

Mr. G. D. Leslie, R.A., who was present, delivered an address, in the course of which he said:—I know full well of my own shortcomings and failures—how almost entirely they have been owing to my dislike of hard work, and this it is that emboldens me to advocate to you to-night the extreme importance of hard work, but I do not wish to be misunderstood about the sort of work that should be hard. Even as a pleasant by-occupation art should not be trifled with, as the humblest endeavours of the mere beginner, if rightly and conscientiously directed, always command our respect and possess a certain amount of interest and value. Sir Joshua Reynolds in his first discourse said, "If you have great talents industry will improve them; if you have but moderate abilities industry will supply their deficiency;" and Sir David Wilkie modestly took this to heart when young, saying he knew he had no genius, and so he determined to be as industrious as he possibly could,

the result being that he became one of the most celebrated artists of his day. But I do not altogether agree with Sir Joshua in his remark, and I feel sure that it was not mere industry that made Wilkie what he was. There is no greater nuisance than an industrious fool, and the mischief he does is exactly in proportion to the amount of his industry. In art the worst artists are often the most industrious, and that is why we are so overwhelmed nowadays with bad pictures. There is another story related of Sir David Wilkie, which gives the real clue of his greatness. His mother said that when he was quite a youth she frequently overheard him, whilst at work, saying to himself, "Paint it weel, Davy"—conscientiousness, the endeavour to do as well and as truly as you can. This is what, no doubt, Sir Joshua intended would supply the place of genius. There should be the feeling that you cannot allow work to leave you with bad drawing, faulty perspective, difficult bits slurred over, false exaggerations or untrue tone or colour. You may have painted a carpet in your picture very carefully and industriously, taking possibly a week to do it, but after it is all done, if you find out for yourself, or someone else points out to you, what so frequently happens, that it looks sloping down to the spectator and not lying flat, and if, feeling this to be true, you, to save yourself the trouble of rubbing it out and repainting it, allow the picture to go from you as it is, trusting that people will admire the patient way you have rendered the pattern, &c., and never notice the bad perspective, then I say you are no true workman, and can only rank yourself amongst the noble army of industrious fools. A great deal of the badness of modern art results from ignorance, but this sort of badness is not half so bad as that of the impudent and unscrupulous artist who habitually violates his conscience, who makes daubs and blotches do duty for detail, puts senseless fussiness to represent intricacy, exaggeration of effect to supply the place of true force, and weak sickliness for delicacy; or, on the other hand, fills his subject with elaborate and painstaking niggles in proportion and drawing. It is this sort of thing which makes a picture contemptible and worthless. It is far better for you and me to take it for granted, along with Sir David Wilkie, that we are not geniuses of such a high order as to produce works in which people will tolerate such wilful faults of omission and commission—such faults, for instance, as we pass over in Raphael and Phidias, in Turner or Tintoret—but first, selecting only such subjects of simplicity and originality as appeal to our hearts and are within the scope of our abilities, to strive patiently to carry out our work in an honest and straightforward manner, and make the very best job of it we are able. Everyone has some individuality, and if we work in this humble and conscientious spirit this individuality will be sure to display itself, and who knows but that sooner or later those who are true judges may accord to it the coveted name of genius? And even if this does not happen, our work will always have a certain value, as all honest and faithful attempts at the representation of nature always must. Let us choose simple subjects, and by hard conscientious work let us strive to make them interesting—that is the best advice possible. It is of not nearly so much consequence what the thing is that is painted as it is how it is painted. A white china tea-cup on a white table-cloth—there are very few people in this room who could render that simple subject satisfactorily—I am quite sure I am not one of them. It is such a capital exercise, though, to try, that I confidently recommend the subject to you. Do not despise this sort of work—honest conscientious work is the sure foundation of all true art.

### SCHOOL BUILDINGS IN BIRMINGHAM.

A REPORT from the Sites, Buildings and Repairs Committee was presented at the last meeting of the Birmingham School Board. It stated that the approval of the Educational Department had been obtained to the purchase of two additional sites for schools in Muntz Street and Garrison Lane, and in accordance with the resolution of the Board instructions had been given for the conveyances to be prepared and the purchases to be completed. The committee recommended that the architects be instructed to prepare plans for a school, to accommodate about a thousand children, to be erected on the site in Camden Street, the general arrangements to be similar to those adopted in the school in Stratford Road, and to include provision for teaching cookery. The report having been received, Mr. Kenrick proposed that the architects be instructed to prepare plans for a school to be erected in Camden Street. An amendment was proposed by Mr. Greening to the effect that the plans of the school be thrown open to competition. It was seconded by Mr. Ingall and supported by the Rev. T. J. Haworth. Mr. Kenrick, in reply, said he regretted the discussion which had taken place, because he necessarily spoke with imperfect knowledge. They had only one school erected and opened which had been built from competitive plans, and had had no opportunity of seeing how it worked. He had no fault to find with the school, but it was

not right to say it was perfect. The second school was not yet built, and it would not be opened before the middle of next year. Under these circumstances he said they had not given the experiment time to be completed, and therefore they could not be in a good position to judge whether it was successful or not. For that reason alone the committee would be justified in asking the Board to go on with the old plans before asking for new ones. The Department had put a bar to the extravagant expenditure of money by limiting the sum to 10*l.* per head. In the last school in course of erection they had to reduce something after the tender was accepted in order to bring the amount down to 10*l.* per head. If the competition was open they would have to pay 5 per cent. for the whole of the cost of building, whereas now they only paid their architects 5 per cent. up to a certain sum, and 2½ per cent. after. In reply to Mr. Greening and the Rev. W. H. Poulton, the Clerk said that they paid the architects 250*l.* a year salary for whatever work might be done. If they had work beyond 5,000*l.* they got an extra 2½ per cent. On the amendment being put 7 voted in favour and 7 against. The Chairman gave his casting vote against the amendment. On the resolution being put 7 voted for and 7 against. The Chairman voted in favour of the resolution, and the report was approved.

## Bygones.

"Antiquity after a time has the grace of novelty."—HAZLITT.

### HOW LORD ELGIN ACQUIRED THE PARTHENON SCULPTURE.

*Concluded from last week.*

DID Monsieur Choiseul take down any of the metopes and the frieze?—One piece of the metope and some of the frieze; the metope I bought at a public sale at the custom-house. It was at the time I returned from France; my things were dispersed all over the country, and my agent told me of some packages in the custom-house without direction, and I gave four or five-and-twenty pounds for them at a lumber sale.

Thinking those packages to be your lordship's?—Yes.

When your lordship heard of those cases being to be sold at a rummage sale, did your lordship make any application to the Government, stating that they had any interest in it, and that therefore you ought not to be obliged to purchase?—No, certainly not.

It was a matter of private purchase?—Yes; these things had been left at Athens during the whole of the French Revolution. Bonaparte allowed a corvette to call and bring these things for Monsieur Choiseul, who was an intimate acquaintance of Monsieur Talleyrand's: from the delay which occurred they did not get away in time to escape our cruisers. Monsieur Choiseul applied to me to make interest with Lord Nelson, and I wrote to him, and he directed them to be sent home, and applied to Lord Sidmouth and Sir Joseph Banks, wishing Government to make such a purchase as to secure the captors, but at the same time to restore the articles to Monsieur Choiseul. When I left Paris Monsieur Choiseul remained in the belief that they were still at Malta, consequently I had no clue to guess these were his at the time of the purchase in the year 1806; but I immediately wrote to him to state what these things were, as I had no doubt they were his by the metope; and in the year 1810 he wrote to me stating that his were still at Malta: when I went over to Paris last year I took a memorandum with me for him, and satisfied him they were his; but he has never yet sent about them, and I do not know what he means to do at all; but there they are, marked among my things as belonging to him.

Does your lordship know that, subsequent to your coming away, and during the time we were at war, any similar permission was applied for and obtained by the French?—I do not know anything about that; but, in point of fact, my cases were at the harbour during the whole of the war, and if the French Government had had anything they could have put afloat they would have taken them.

Did that seizure apply to the property of all English characters, or did it apply to your lordship's as a public character, and therefore the property of the country?—Besides the boxes at the harbour, Lusieri's magazines were filled in the town of Athens, and immediately after his flight they broke those open, and sent them to Yanana, and from thence to Bonaparte.

Was not Lusieri considered as an agent of your lordship's in your public character?—No, certainly not.

Your lordship had applied for him to do what he was doing, and was he not in that way considered as your lordship's agent,

and therefore subject to the same liability as your lordship was, to have whatever was in his possession seized?—He was considered as an English subject, as far as his connection with me went; but his property was stolen, in fact: his property and mine was promiscuously taken; they did not do it officially.

Was any objection made by the chief magistrate of Athens against taking away these marbles, as exceeding the authority received from Constantinople?—There was no such objection ever made.

Was ever any representation made of any kind?—None that I ever heard of.

Does your lordship believe, to the best of your judgment, that you obtained, in your character of ambassador, any authority for removing these marbles which your lordship would not have obtained in your private capacity through the intervention of the British ambassador?—I certainly consider that I obtained no authority as given to me in my official capacity (I am speaking from my own impression); the Turkish Government did not know how to express their obligation to us for the conquest of Egypt and for the liberality that followed from Government, and of course I obtained what I wanted; whether I could have obtained it otherwise or not I cannot say. Lusieri has obtained the same permission seventeen years, in the course of which time we have been at war with Turkey. Monsieur De Choiseul had permission under very different circumstances; but, in point of fact, I did stand indebted to the general goodwill we had insured by our conduct towards the Porte; most distinctly I was indebted to that; whether Monsieur Choiseul's example could be quoted or not is a matter of question.

In your lordship's opinion, if Lord Aberdeen had been at Constantinople at the time your lordship was ambassador there, could you have obtained the same permission for Lord Aberdeen as an individual that you did as ambassador obtain for yourself?—I can only speak from conjecture. The Turkish Government, in return for our services in Egypt, did offer to the British Government every public concession that could be wished. They were in a disposition that I conceive they would have granted anything that could have been asked; I entered upon the undertaking in the expectation that the result of our expedition for the relief of Egypt would furnish opportunities of this sort.

Then the result of the impression on your lordship's mind would be that other advantages granted by the Turkish Government were on the same principle as the permission to your lordship to remove these marbles, and rather out of public gratitude for the interference of England?—I believe it was entirely that, and nothing else. I was not authorised to make any application in the name of Government for this; but I wish it to be distinctly understood that I looked forward to this as that which was to enable me to execute the plan; and to that I am indebted for it. Whether under other circumstances I could have obtained the facilities Monsieur Choiseul had had before I cannot answer.

When your lordship received this, which you considered as a proof of the public gratitude of the Turkish Government to England, did your lordship mention the circumstance in any of your despatches to Government?—I should suppose not in any other despatch than that which has been alluded to.

That was upon leaving Turkey, was not it?—Yes.

If your lordship considers it as a mark of the public gratitude of the Porte to Great Britain, does not your lordship consider that mark of gratitude essentially connected with your character of representative of the Court of Great Britain at the Porte?—I did not ask it in that character, nor did I ask it as a proof of the disposition of the Porte, but I availed myself of that disposition to make the application myself.

Does your lordship suppose that if that application had been made at that particular period by any other person than the ambassador of Great Britain it would have been granted?—In my own mind I think it would, if he had had means of availing himself of it; that is to say, if he had determined to risk his whole private fortune in a pursuit of such a nature.

When your lordship mentioned that general disposition of the Turkish Government, do you mean that it was as well to individuals in their private capacity as to any demand made by the Government?—To everybody.

In short, it was a disposition of goodwill towards Englishmen?—Of cordiality towards Englishmen to an extent never known before.

In making the application to the Turkish Government for permission to remove these marbles, did your lordship state to them the objects you had in view in so removing them, whether for the purpose of collecting an assemblage of these things as matter of curiosity for yourself, or for the purpose of bringing them to this country for the improvement of the arts?—In explanation it must have been so stated; whether there was any formal application bearing upon your question I cannot undertake to say.

Was it or not stated to the Turkish Government that it was for the purpose of forming a private museum or for public uses?

—I am afraid they would not have understood me if I had attempted a distinction.

In what way did your lordship distinguish, in your applications to the Turkish Government, between your private and public capacity?—I never named myself in my public capacity, not having authority to do so; this was a personal favour, and it was granted quite extra-officially to me.

And asked as such?—Asked as such, and granted as such.

The firmans granted to your lordship were not, as the committee collect from your statement to-day, permissions to take particular pieces, one from the city and one from the citadel, and so on?—No, I had never been at Athens, and could not specify anything.

In point of fact, the firman was not so?—It was not; there could not have been an application for specific things.

Suppose the transaction had passed in this way, that your lordship was anxious to have some of these marbles, the Government were willing to grant you a limited permission to take one or two pieces?—Certainly it was not so; it must have been quite general.

Your lordship has no certain recollection how it was?—No, only that I did not know anything of the state of Athens, and consequently my application must have been general.

#### Second Day.

The Earl of ELGIN again called in and examined.

Will your lordship be pleased to state the view under which the collection was made?

[The Earl of Elgin, in answer, delivered in the following papers, which were read.]

"A letter dated London, February 14, 1816, signed Elgin, addressed to the Right Honourable Nicholas Vansittart.

"A memorandum as to his lordship's exclusive right of property in the collection, dated February 1816."

"A memorandum as to the delay in transferring the Earl of Elgin's collection to the public."

Has your lordship any account from which you can state to the committee the actual sums which your lordship has paid in obtaining these marbles, and in transporting them to this country?

[His lordship handed in a copy of a letter addressed to Mr. Long on May 6, 1811, with a postscript dated February 29, 1816, addressed to the chairman of this committee, which was read.]

Has your lordship any paper which exhibits the total?—No other than as it is stated in that letter, which I do not offer as a precise account, but it is merely to inform the committee what was the nature of the expense.

Was any specific offer as to price for obtaining those marbles for the public made to your lordship by Mr. Perceval, and in what year?—Yes; I believe it was a few days after the date of the above letter to Mr. Long, in the name of Mr. Perceval; he did intimate to me, as I understood, that Mr. Perceval would be disposed to recommend the sum of 30,000*l.* to be given for the collection as it then stood.

What passed in consequence of that offer?—I believe it is mentioned in the memorandum which I have given in accounting for the delay—paper marked No. 3—and which exactly states the grounds on which I declined the offer; it follows immediately after the extract from the Dilettanti publication, in these words:—"So that when Mr. Perceval, in 1811, proposed to purchase this collection, not by proceeding to settle the price upon a private examination into its merits and value, but by offering at once a specific sum for it, I declined the proposal as one which, under the above impressions, would be in the highest degree unsatisfactory to the public, as well as wholly inadequate either in compensation of the outlay occasioned in procuring the collection or in reference to (what has since been established beyond all doubt) the excellence of the sculpture, and its authenticity as the work of the ablest artists of the age of Pericles."

Mr. Vansittart never made any specific offer on the part of the public?—No, never except in what passed last year, which was afterwards dropped.

What further has passed relating to the transfer of those marbles to the public since 1811?—In the spring of 1815, Burlington House having been sold, Lord George Cavendish intimated a desire that I should remove the marbles from thence in consequence. I applied to the Trustees of the British Museum to take them in deposit, considering that the circumstances of the times might not make it convenient for the public to enter upon the transfer. In reply, the British Museum rejected my proposal as not being consistent with their usual mode of proceedings, and they appointed three of their members to enter into negotiation with me for the transfer, which nomination, after some discussion, led to the petition which I presented to Parliament in the month of June following.

Is there any price, in your lordship's estimation of these marbles, lower than which you would not wish to part with them?—No, there is no standard fixed in my mind at all.

Are there any persons by whom this collection has been valued?—Not any one, to my knowledge.

Are the gentlemen mentioned in the list you have delivered in designed on your lordship's part to be examined as to the value of the collection?—I gave in that list as thinking them proper persons, without consulting them on the occasion; they are the individuals best acquainted with the subject, and I fancy it would be satisfactory to the public that they should be examined.

Are there any and what additional articles now offered that were not included in the offer to Mr. Perceval in 1811?—To the best of my knowledge about eighty additional cases of architecture and sculpture have been added, and also a collection of medals.

#### GENERAL.

**Mr. Ernest Hart** has consented to deliver an address at the Parkes Museum, on December 20, on the subject of "The New Local Government Bill, especially in relation to Sanitary Administration."

**Mr. Gilbert D. Boulton**, of Kensington Studios, youngest son of Mr. R. L. Boulton, sculptor, of Cheltenham, has been successful in competition, and gained a scholarship at the Government Art Training Schools, South Kensington.

**Sir J. H. Thursby** has written to the Mayor of Burnley, offering to give a plot of ground of about 28 acres, and worth 20,000*l.*, as a public park for the town.

**Mr. Henry Tate** has signified, through Lord Derby, the president of the Liverpool University College, his intention of giving 16,000*l.* for the erection of the library block of the college. Mr. Tate's name will be associated with the new college library.

**Messrs. McDowall, Steven & Co.**, of Glasgow, have offered to the Corporation as a gift to the town the fountain they had erected in the Exhibition Grounds opposite the Museum Buildings. The Lord Provost, in accepting the offer, said the valuable gift was a good specimen of Glasgow work, of artistic beauty and finish.

**Professor Armstrong** opened the Engineering Class in Edinburgh University last week, and stated that the Senatus had decided to apply the bequest of 3,000*l.* made by the late Mr. J. Fulton for the equipment of a mechanical laboratory. In his address, the Manchester Ship Canal, the Forth Bridge, the piers of which were as high as the dome of St. Paul's, and the great engineering works throughout the world were noticed.

**Mr. Leader Williams**, engineer of the Manchester Ship Canal, and a party of English engineers and surveyors, visited Ballinasloe on Saturday, and inspected the new bridge and sluices, with the view of constructing similar works on the Manchester Ship Canal.

**The Gloucestershire Magistrates** propose that a portrait of Sir John Dorrington shall be painted and added to the series of portraits of previous chairmen of the County Quarter Sessions.

**The Industrial Exhibition** at Vienna, which closed on Friday, has cleared a sum of about 12,000*l.* net profit.

**The Promoters** of the Glasgow and Suburban Subways have, it is stated, owing to the opposition by the magistrates and Town Council of Glasgow, decided not to renew the application for it next session.

**The Theatre** which is to be erected at Buxton, for the Gardens Company, Limited, from the designs of Mr. W. R. Bryden, architect, will provide accommodation for 850 players. The gardens will be enlarged to the extent of 30 acres, as the Duke of Devonshire has offered the Serpentine Walks for the purpose.

**The Theatre Royal**, Cowcaddens, Glasgow, has been sold by auction with the adjacent buildings, comprising dwelling-houses, &c. It was knocked down to Messrs. Howard & Wyndham at the reduced upset price of 7,500*l.* The building was erected in 1867 at a cost of 30,000*l.*

**The Dundee Town Architect** estimates that 2,000*l.* will be required to restore the stone work of the town's churches.

**The Tower of All Saints' Church**, Bromsgrove, which has been built from the designs of Mr. John Cotton, of Birmingham, was dedicated on Wednesday.

**A Winter Exhibition** is to be held at Olympia, from December 1 to February 23, 1889. The main features are to be manufactures and industries, art galleries, a fair of all nations, promenade concerts, and a children's pantomime.

**Considerable additions** have been made to the hospital, Lodge Road, Birmingham, the ventilation of which has been carried out on the Boyle system, the latest improved form of the Patent Self-Acting Air Pump Ventilator being adopted for the extraction of the vitiated air.

**CRIMINAL PROCEEDINGS**, under the new Merchandise Act, will be instituted against any person falsely representing any form of ventilator to be a Self-acting Air-pump Ventilator, said title being registered and our Trade-Mark, applicable only to ventilators manufactured by us. Any infringement renders the person infringing liable to two years' imprisonment.

ROBERT BOYLE & SON, LD.

## CONTRACTORS TO H.M. GOVERNMENT.

INTERNATIONAL HEALTH AND OTHER EXHIBITIONS—MEDALS AWARDED FOR

## LEGGOTT'S PATENT ADJUSTMENT

CONTINUOUS OPENER.

SILENS.

THE SILENS, for Fanlights, Skylights, &c. Is admitted to be the best ever put before the Public. Can be adapted to any kind of window. Size and height of window no object.

From 4/3 each.

The WILMOS is worked with a rod or endless cord. It is extremely neat, and can be fixed to open either top or bottom, inwards or outwards; no cutting away of frame required. When worked with a rod is most efficient for Public Buildings, as the key can be loose. For Price Lists, Illustrations, and Testimonials, write as below.

For Continuous and other Lights, Estimates given.

WILMOS.

NO CUTTING AWAY OF FRAME REQUIRED.

## TESTIMONIAL.

SIRS,—I have pleasure in testifying that I have used Leggott's Silens Adjustments for various buildings to high skylights, fanlights, and top parts of windows, and in every case they gave satisfaction. They are secure in whatever position, whether the window is open or closed, and are quite simple and workable in their action. I prefer them to any other that I have seen or used for the above-mentioned purposes.  
Messrs. W. & R. LEGGOTT, Bradford.

BANGOR: N. Wales: Sept. 14, 1885.

I remain, yours obediently,  
R. DAVIES Architect.

Considerably Reduced Price List, November 1, 1887.

ALL WORK ENTRUSTED TO US GUARANTEED SATISFACTORY.

TRADE NOTES.

WE have received from Mr. Wilson Hartnel, electrical engineer, Park Row, Leeds, a small catalogue in which most of the installations he has conducted are enumerated. Amongst them we notice the following clients:—Yorkshire College, Leeds; Barnsley Co-operative Society, Limited; Leeds Forge Company, Leeds; Thwaites Bros., Bradford; Marshall, Sons & Co., Gainsborough—out of a list of no less than a hundred installations for residences, manufactories, &c. This is very flattering to the efficiency with which Mr. Hartnel conducts his work.

THE scaffolding for the rebuilding of Lynn Church tower has been fixed and the work started.

THE parish church of St. Peter, Widmerpool, has been reopened. In the work of restoration a stained-glass window, by Messrs. Heaton, Butler & Bayne, has been placed in the west wall. The building is lighted by thirteenth-century lamps, supplied by Messrs. de Wilde, of Archer Street.

A PAINTED window is to be placed in the south transept window of the parish church at Cheltenham as a memorial of Mr. Brooksmith, M.A.

Surveying and Mathematical Instruments, THEODOLITES, LEVELS, SEXTANTS, COMPASSES, CHAINS, TAPES, DRAWING INSTRUMENTS, ETC., ETC.

Twelve-inch best Boxwood Scales, divided in any manner, 1s. 6d. each; by post, 1s. 8d.

Twelve-inch best Ivory Scales, 7s. 6d. each. New Builder's Level, ten-inch, with parallel plates, mahogany case and tripod, £4 4s.

Student's first-class set Brass Mathematical Instruments and Scales, as supplied to the War Office, £1 1s.

ILLUSTRATED AND DESCRIPTIVE CATALOGUE SENT POST FREE TO ANY ADDRESS.—Ask for "SURVEYING LIST."

white lead used is ground on the premises, and, judging by the great demand made for the paint, it has special qualities. Mr. Ireland carries on several other industries on the same works—in whiting, plaster of Paris—putty, and has a large demand for Portland cement.

### NOTES ON NOVELTIES.

**Patent Water-closet for Cottages flushed with Slop-water.**—This apparatus, patented by Messrs. Duckett & Son, of Burnley, Lancashire, seems to us very ingenious, and well

with inlet and outlet in various positions to suit drains. The apparatus is simple, and, being made from salt-glazed earthenware, will be durable. We understand that it is now being adopted in Burnley, Brierfield, Nelson, Colne, Accrington, Rishton, Blackburn, and other places, and that it is highly appreciated by the property owners and the town officials. The application of slop-water for this purpose is very desirable, as it saves the town's water, which in many towns is an important consideration.

**Mouldings.**—In a recent visit to Leeds, we had the pleasure of inspecting the saw-mills of Messrs. W. Scupham & Sons—a firm whose reputation is not confined to the locality, but extends to

worth the attention of builders, architects, and property owners. Referring to our illustration—A is self-acting tilting vessel, of salt-glazed earthenware. It flushes 3½ gallons, and is supported with brass steps and axles to prevent corrosion. It tilts when nearly full, and discharges with great force through the closet trap. It is provided with rubber bumper to prevent liability to breakage. B is a salt-glazed earthenware box to receive the tilting vessel. C is a salt-glazed earthenware dish-brick, 20 inches by 18 inches by 4 inches, entirely covering tipper box. Grating, 7 inches square, secured with brass bolts to prevent children from removing it. D is closet trap made

every part of the country—and were extremely interested in looking over the numerous departments, for the evidence of unusual enterprise is seen in everything. In the first place, the firm import their own timber and season it. There are departments for making furniture, picture frames, every description of door furniture, railings, balusters, and particularly mouldings. They are the manufacturers also of Longbottom's patent adjustable lock furniture, in ebony, oak, partridge, walnut, and other woods. Messrs. Scupham & Sons claim a special advantage in manufacturing entirely from well-seasoned timber, and guarantee the durability of their work. We should certainly

say, from an inspection, that it would be difficult to excel the firm either in quality or price.

#### BUILDING IN GREENOCK.

At the last meeting of the Greenock Dean of Guild Court Dean Jameson gave an account of the business done during the twelve months ended 1st November. The number of processes for formation and levelling of streets and the construction of sewers was 38, a decrease of 9 as compared with last year. Petitions for new buildings and alteration of buildings 182, an increase of 53. Petitions for street openings for water supply, service drains, &c., 509, an increase of 360. Petitions for hoards for buildings 32, an increase of 8. The total increase on the number of the various petitions was 412. The Court sat 28 times, and there was only one appeal, in which case decision was reversed by the Court of Session. Amongst the buildings for which plans were passed were ten tenements, a hall and school, 20 for miscellaneous business purposes, and 57 for sanitary improvements. Accommodation has been provided in the plans passed for 53 families. The number of buildings in course of construction or undergoing alteration at the present time is 25, including 8 tenements. Owing to the decision of the Board of Police for dispensing with the Dean of Guild inspector of buildings, the additional work done in the Master of Works' department, exclusive of examination and reporting on plans, &c., has been very great, involving no fewer than 3,016 visits of inspection, while the notices sent out numbered 549. Although the cases had increased, the value of the properties passed was 29,000*l.* less than last year. It was explained, however, by Mr. Turnbull, master of works, that there had actually been a great deal more work going on than during the previous year. The value of the work which had been going on was 34,200*l.*, while in 1886-87 the value of the work carried out was only 32,600*l.*

#### SOCIETY OF ENGINEERS.

At a meeting of the Society of Engineers, held at Westminster Town Hall, on Monday evening, November 5, Mr. A. T. Walmisley, president, in the chair, a paper was read on "The Practice of Foundry Work," by Mr. H. Ross-Hooper.

The paper briefly compared the particular qualities and properties of pig-iron, with the view of determining the varieties

which are best adapted to the requirements of the different kinds of castings made; and showing how the nature of cast-iron depended not only upon the amount of carbon that it contained, but upon the conditions under which that carbon existed. The author then proceeded to illustrate how the failing of portions of a cast-iron structure may be traced to a want of knowledge in the way the lines of crystallisation flow on the cooling of the metal, and mentioning the weak points to be guarded against in the designing of cast-iron work. Moulding or the production of a hollow mould to receive the metal was next considered; for to mould melted iron into any required shape or form two things are necessary, (i) a pattern of the article to be produced, (ii) a substance which will retain the impressions of the pattern made upon it and resist the violence of the metal when poured therein. To make a pattern a man requires to be thoroughly conversant with the principles of moulding, to so construct it that it may give a minimum of trouble to the moulder; the materials used for pattern making and the general essential points of this branch being touched upon. The differences between green and dry sand moulding, the requisites of a good foundry sand, and the mode of preparing a mould for a small girder bed-plate were entered into in detail, noticing those particulars which should be observed in the construction of sand moulding, and showing the uses of cores and the method employed in their formation, both large and small.

The author next proceeded to describe the features of loam moulding, illustrating (by means of a working model) the process of constructing a mould for a drum capable of holding 200 feet of 1-inch wire rope used in the erection of the Sukkur Bridge, India.

After explaining the operations of chill casting, malleable cast-iron, and the system of moulding known as "Jobson's Blocks," whereby sand moulds of thin delicate patterns can be made by ordinary labourers, the author mentioned the different modes adopted for casting according to the forms and requirements of the various articles to be produced, and how sound results can only be obtained by a careful attention paid to the feeding of the metal to supply the shrinkage and drawing away which must inevitably occur on the cooling of the metal. The cupola, its construction, and advantages over other types of furnaces, and the manner of charging it, together with the appliances necessary to a foundry in the shape of drying stoves, laddles, cranes, &c., and a "fettling shop" for the ultimate cleaning and dressing of castings were duly considered.

## HOLDEN & CO.'S ZINC & COPPER ROOFING UPON THEIR PATENT AND IMPROVED PRINCIPLES, STAMPED ORNAMENTAL ZINC AND COPPER WORK OF EVERY DESCRIPTION.

Whereby the use of SOLDER and all OUTSIDE FASTENINGS are entirely dispensed with.

Can refer to Works executed in all parts of the United Kingdom as our best recommendation.

The author then treated on the examination of cast-iron work and the care that should be observed in all inspection of the same, and finally discussed the tests usually applied and the general strength of cast-iron.

### DR. KRUGENER'S PATENT BOOK CAMERA.

THERE has arisen such a large demand for a small camera of convenient and portable size that much attention has been paid to improving this useful invention, and we believe it has been patented in Dr. Krugener's patent book camera.

This camera, as its name implies, is like a book, and, with nothing to denote its purpose, can be used secretly, and is therefore a real detective camera.

It holds twenty-four plates—size 4 ct., or 1½ inches, which are exposed in rotation.

The plates are held in metal sheaths—Samuel's patent.

#### Preliminary Explanation.

To open the camera you turn back the catch A, slightly raise the end of the lid B, and pull it out towards you. It will

require rather a smart pull, for the other end of the lid fits somewhat tightly beneath the cross-piece C. To close the

camera, push the lid well underneath the cross-piece G, then bring down the other end, and fasten the catch A.

The dry plates must not be exposed to ordinary light; the insertion must therefore take place in a dark room, or at night time in any room, but only using a lamp with ruby glass or fabric specially made for the purpose. The sensitive plate is inserted into the sheath film side uppermost. Handle the edges and back—fingers on the film side would leave marks. The sheaths are numbered, and should be arranged on the left hand, No. 1 uppermost. Take a sheath by the edge with the thumb and middle finger, and with the forefinger press the bulge of the sheath flat, then with the other hand insert the dry plate, holding it only by its edges, film side uppermost. The bulge in back of sheath acts like a spring, and keeps the plate in its place. When all the sheaths are filled they may then be inserted into the camera. No. 24 is now on top. Slip the sheaths, metal side uppermost, underneath the bar D; the edges fit the metal sides of camera, and slide easily forward to the compartment E, where the metal spring platform should be slightly depressed to allow the sheath to slide over it and under the clamp H. In inserting the sheaths see that the figures on the backs are upright, not upside down. This operation is repeated till all the twenty-four sheaths are in the compartment E. No. 1, however, is not pressed home, but remains in the middle space G, opposite the lens.

PROSPECTUS FREE ON APPLICATION.

## J. HARRINGTON & CO., COVENTRY.

London Address:

398 Fulham Road, S.W.

As stated above, No. 1 sheath is placed over the middle space G, opposite the lens; No. 2 is the top sheath on the platform of compartment E. After the exposure of No. 1, the pusher, I, is pulled out as far as it will go, and then pushed in again close up. By this action the projections or teeth underneath each side of the pusher catch the sheath on spring platform, causing it to move forward, and to push the sheath, previously in position, on to the spring platform of compartment F. This compartment receives all the exposed plates. In order to see that each sheath is pushed forward, there is a little window at J; move aside the cover and the number on back of sheath may be seen. As each bears a consecutive number, it is easy to see if the change has been properly made. Should any sheath not move forward easily, tap the sides or bottom of camera; and if it still resists, pull the knob K, which causes the spring platform to become depressed at one end. Such obstruction will arise from not pulling out and pushing in the pusher the full distance. Empty sheaths must never be inserted in the camera, for they will also cause obstruction.

In setting the shutter pull out gently the string fastened to bead L till a spring is felt to catch—the shutter is now set; then, to fire the shutter, pull out the string of bead M at the bottom of the camera, and when this is fully out it causes the shutter to be released and to descend swiftly past the lens. L is connected with the real shutter; M merely with a safety slide which closes the aperture before the lens. The safety slide is a great advantage, as it allows the shutter to be set previous to exposure without danger of light getting into the camera, so that when the opportunity of taking a picture occurs the exposure can be effected without delay.

The above is the operation for instantaneous exposures. But when a longer exposure is necessary, fasten back the bead L to the eye N; this keeps the shutter open before the lens. It now only remains to pull down the safety slide, when an exposure can be made as long as the string is held. By releasing it the safety slide closes automatically by a spring.

The lens is designed especially for the book camera by one of the best opticians in Europe, and is composed of the achromatic system of lenses (*i.e.* of four lenses) made from the new Jena optical glass. It will be found to give very sharp pictures and correct perspective. Occasionally the front and back outer glasses should be cleaned. For this purpose a small stick covered with leather at one end is supplied. In using, move it with a rotatory movement over the faces of the glasses, and do not apply much pressure. The front glass is got at by

setting the shutter as if for a long exposure, and the back glass through the middle compartment G.

#### Exposure.

To expose, or make the picture:—The apparatus being filled with plates, and No. 1 sheath being above the middle compartment opposite the lens, the shutter should be adjusted as described before, namely, the string of L pulled up, the camera being held under the arm, and when the opportunity for a picture offers, the string of M must be pulled down; this causes the exposure. During the exposure the camera should be held firm and steady against the body.

Things necessary to secure correct exposures and perfect photographs comprise:—1. To practise holding the camera. 2. Position of camera relative to size and nearness of object. 3. Light.

As regards the first, in holding the camera during exposure it is necessary that it should be held upright and held steadily. It would be well for the beginner to practise this a little with the camera empty. A good position is under the arm, pressed firmly against the body, and at the moment of exposure standing quite firm and steady. The camera can be used in other positions—against the chest, or held level with the eyes, &c., but for long exposures it should be placed on some support.

As to the second, the position of camera relative to size and nearness of object:—When the person, group, or object to be photographed is at a distance of five to six paces, the camera should be held the height of the waist. If at ten or twelve paces, then as high as the chest. If at greater distances, then it should be held level with the eye, and the object sighted over the top of the book. In taking full-length portraits of children two to six years old the camera should not be more than a foot from the ground. With the book camera under the arm and the lens pointing behind it is possible to take the portrait of a person walking behind us. This may also be done if a person be quite close to the operator. The apparatus may be held in the hand, and the shutter (see previous description) left off when the person is, say, within four paces; in this manner very fine bust portraits can be taken, which are remarkable for sharpness and natural expression. With a little practice distances can easily be estimated, and then satisfactory pictures can always be obtained. We again repeat, whilst the picture is being taken the camera must be held very steady.

Thirdly, on light:—The book camera is principally intended for use in the open air and in a bright light; that is to

say, it should not be used in narrow dark streets, or at objects under the shade of trees or buildings, and, of course, not in interiors unless a long exposure is given. But when the camera is set for long exposure (as described before under setting the shutter) and resting on some firm support, such as a table or a wall, then it may be used anywhere, sufficient time being given for the exposure. This will vary according to the amount of light—for instance, in a well-lighted interior about eighty seconds, in a badly-lighted interior say from five to eight minutes. A little practice will soon give the user the power of judging. The lens is some distance in the camera, therefore it is not necessary that the sun should be always behind one's back unless very low down in the sky.

The following rules are important :—1. Whenever a picture has been taken another sheath must be immediately pushed forward in its place, and the number of the displaced sheath should be noted. There will then be no doubt that the sheath in position behind the lens has never been exposed.

2. If only a certain number of the twenty-four sheaths containing the sensitive plates has been exposed, and it is desired to develop them, the one over the middle compartment must remain, and only those in compartment F removed for the purpose of development.

3. When a sheath with the sensitive plate is being shifted, the cover of the window J must not be left open. It should only be opened before or after. The window is only opened to make sure that the consecutive number is really in its place.

4. The camera should not be exposed unnecessarily to the sun; however, in diffused light it may be carried under the arm.

Dr. Krugener notes that, in order to spare disappointment to those who wish to use the pocket-book camera in the autumn or winter, and who are but little acquainted with the nature of photography, it should be mentioned that the action of the light on the photographic plate is much feebler from October to March than during the summer months. In the winter months, therefore, the picture should be taken only about mid-day, say from 12 to 2 P.M. at the latest, and then only in very clear weather, except when snow has fallen, and then good pictures may be obtained in less clear weather, if the distance is of no importance. At the commencement of spring the action of the light increases very rapidly and attains its greatest intensity in the months of May, June, July, and August, and diminishes quickly towards the end of September. The apparatus then must not be found fault with if a successful

picture cannot be obtained at four o'clock of an October afternoon, but by carefully following the instructions a good result will certainly be obtained.

#### *Development of Plates.*

The pictures taken with the pocket-book camera should never be developed with the ferro-oxalate developing solution, as the deposit with the same is not sufficiently delicate, and this detracts greatly from the sharpness. The developing solution made with pyrogallic acid is the best, as very sharp and detailed small negatives can be obtained with it, and owing to its great strength and its being easily manipulated, it should always be employed for instantaneous photographs. The following formula has proved very serviceable for developing the plates supplied with the pocket-book camera :—

1. Dissolve 1 oz. 6 drachms of crystallised pure carbonate of soda, and 1 oz. 12 drachms of pure crystallised sulphite of soda in  $1\frac{3}{4}$  pints of spring water, and let the solution be filtered, or allowed to settle until it is clear. Also :

2. Dissolve 1 oz. 1 drachm of sulphite of soda in  $3\frac{1}{2}$  oz. of water, and add diluted sulphuric acid (1:10) until blue litmus paper is slightly reddened by it; 154 grains of pyrogallic acid are then added.

In order to develop six pictures, take 7 drachms of Solution 1, 51 minims of Solution 2.

Those who prefer not to trouble themselves with preparing the developing solution can obtain it ready mixed from the firms which sell Krugener's pocket-book camera, and instructions for use are supplied at the same time. In order to carry out the developing process conveniently, and since the plates, owing to their small size, cannot well be held between the fingers, each plate should be secured in a small holder specially constructed for the purpose, so that it is turned upwards, and therefore stands above the developing tray.

Six plates should be placed with their respective holders in a suitable tray, which is so arranged that 7 drachms of fluid will be sufficient for developing. When the plates have been developed, they are placed for a minute in a thin alum bath (1 part

to 10 of water), and afterwards in the fixing hyposulphite of soda bath (1 part to 4 of water). After the plates are fixed they are placed upright in the washing vessel, which is effected by laying the holder on its side. When the plates have been thoroughly washed they are set to dry, but still remaining between the holders, from which they must not be removed until they are completely dry. It will be readily perceived how convenient this manner of preparing the plates must be, since the fingers do not come at all in contact with the baths. As the holders are very cheap, a stock should be bought, so that they may never run short. These holders and the developing trays are also to be obtained from the above-named firms.

#### Printing the Pictures.

In order to print the negatives, a specially constructed printing frame must be employed in which ten pictures can be printed at the same time. These printing-frames do not cost more than others, and can be obtained from the firms which supply the cameras. Those who wish to enlarge the negatives afterwards with Marion's enlarging apparatus must take care to

keep them thin while developing; that is, they must not be over-developed. The addition of bromide of potassium is not necessary for this purpose, since it is only a question of the details in shade. Keeping the negatives thin is advantageous in two ways, since they then serve for producing a good enlargement and also for printing on "Aristo" paper. For printing these delicate negatives the chloride of silver collodion paper, known as "Aristo" paper, is the most suitable. This paper reproduces all the details so truthfully that the small pictures appear larger than they really are. This paper can also be handled easily and safely, which is worth the consideration of amateurs. Precise instructions for use will be found contained in each packet, so that they need not be repeated here. Moreover, it is not intended to convey precise instruc-

tions here respecting the whole process, but merely to give hints which may lead to satisfactory results. The wonderfully brilliant pictures produced by Krugener's pocket-book camera

result from the combination of favourable conditions, such as glass plates, a very sharp objective, a developing solution which gives a very fine deposit, and printing on "Aristo" paper. The first two conditions are inherent in the camera, and whoever attends to the last two cannot fail to obtain highly satisfactory results.

Messrs. Marion & Co., of Soho Square, London, W., are selling these cameras at a price which is within the means of the youngest student, viz. 65s., including twenty-four metal sheaths.

#### EDINBURGH WATER-SUPPLY.

THE opening address of the East of Scotland Engineering Association was delivered by Mr. J. B. Bennett, C.E., president of the Association, who chose for his subject "An Historical Sketch of the Edinburgh Water-Supply." It was stated that

the first Act of Parliament authorising the introduction of a water-supply to the city was obtained in 1621, though no steps were taken to carry out the scheme till 1674, when Peter Bruschi, a German, was employed to bring in water from springs at Comiston by means of a lead pipe 3 inches in diameter to a cistern on the Castlehill, at a cost of 2,950*l*. The quantity of water thus supplied was equal to 4½ gallons per head per day, and at first five public wells were considered to be sufficient for the wants of the inhabitants, though this number was soon doubled. A further Act was obtained in 1755, and in 1791 the water of springs at Bonaly was led into the city by means of cast-iron pipes. Up to the end of last century no special water-rate had been imposed, but further supplies being necessary, the Edinburgh Water Company was incorporated in 1819, and took over the existing works, and in 1822 introduced the Crawley water-supply, which raised the quantity provided to twenty gallons per head per day to the combined populations of Edinburgh and Leith, though the supply was not extended to the latter place till 1826. The various sources of supply acquired by the water company and the works executed under the superintendence of its engineers—Mr. Jardine and Mr. James Leslie—down to the time of their transfer to the Water Trust in 1870 were described, and reference was made to the Parliamentary struggles connected with the creation of the Water Trust and the St. Mary's Loch Scheme of 1870 promoted by that body, the Bill for which was rejected by the House of Lords Committee after having been passed by the Committee of the House of Commons. The Moorfoots works executed by the Water Trust and the present proposals for an increased supply were considered.

#### THE BRITISH DEPARTMENT IN INTERNATIONAL EXHIBITIONS.

THE absence of interest by the Government in the British section of foreign exhibitions has drawn from Mr. G. Collins Lesley the following remarks:—

It is not too much to assert that the position occupied by this country at every continental exhibition since that held at Paris in 1878 has been the reverse of creditable. Our Government has jumped from one extreme to the other. After being generous, perhaps lavish, in its expenditure at Paris in 1867 and 1878, at Vienna in 1873, and at Philadelphia in 1876, it

made a *volteface* and rushed to the other extreme. The British court at the Melbourne Exhibition of 1880-81 was only prevented from failing, so far as decoration was concerned, through the personal popularity of Sir Herbert Sandford, who was the representative of the Royal British Commission, and the good feeling of the local commissioners, who fitted up the British court out of their own funds, so that it was enabled to compete successfully with its neighbours—France, Germany, Italy, and Austria.

Again, at Amsterdam in 1883 and at Antwerp in 1885 the representative of the British exhibitors had to do his best without any official countenance or support to make his court look presentable, while those of France and Germany had the advantage of a large expenditure by their respective Governments.

A small vote was indeed granted for the Adelaide Exhibition of last year, and this country had the advantage of being represented by Sir Herbert Sandford. But the Melbourne papers are loud in their complaints about the parsimony of the British Government at the exhibition now being held at the capital of Victoria, and contrast with no advantage to this country the difference presented by the appearance of the British and the German courts. The truth is that the Royal Commission appointed by this country for the Melbourne Exhibition contented itself with getting together a large collection of loan paintings, intrusted the representation of British interests to a local banker, Sir George Verdon, and endeavoured to throw the cost of decorating their court, as in 1880, upon the colonial commissioners.

I am afraid that the poverty of the British court at Barcelona is the fault of the Spanish officials who organised the exhibition and made two blunders in its management—the first being that they postponed the date for holding it from 1887 to 1888; the second, that they confided their interests in this country to something like a score of gentlemen, myself included, without telling any of us very clearly what we had to do, paying very much heed to our recommendations, or making it worth our while to take much interest in the Exhibition. I do not think that the Exhibition at Copenhagen was ever brought very prominently before the British public, and the court at Brussels is wonderfully good considering that Mr. Lee Bapty had no assistance from either Government or committee, and it had the merit of being the only portion of the Brussels Exhibition which was ready at anything like the date appointed for the opening.

## Wilson's Patent Dioptrical Pavement Lights.

WILSON & CO. beg to call the attention of Architects and others to the superiority of Wilson's Patent Dioptrical Lenses for pavement and floor lights. These Lenses are constructed on strictly scientific principles, and have been approved by some of the highest authorities on Light. They are made of the Best English White Flint Glass of high refractive power, and transmit more light than any other form of Lens yet introduced. The reflecting surface being spherical, the rays of light are distributed in every direction.

Wilson's  
Patent Lenses  
for  
Floor Lights,  
Deck Lights,  
and  
Pavement  
Lights  
of every  
description.  
Sample Lenses

Wilson's  
Patent Lenses  
for  
Stall Boards,  
Cellar Flaps,  
Ornamental  
Tile & Glass  
Pavements.  
Safety Coal-  
Plates.  
Plans, Prices  
and Estimates  
Free.

Fig. 1 shows how the ordinary prism or semi-prism, by receiving the rays on a plane reflecting surface, throws them forward at one angle only, in parallel lines close to the ceiling.

Fig. 2 represents the Patent Dioptrical Lens, and shows by comparison how the rays of light, striking on the curved inner surface, are reflected forward through the face of the lens in every direction, filling the whole angle of 90°, thus illuminating the apartment from floor to ceiling and from wall to wall.

From the above diagram it will be seen wherein consists the advantages claimed for Wilson's Patent Lenses. The objection to the semi-prism is that it reflects the light, as shown in Fig. 1, at such an angle as to be of little use, and more especially if the line of the ceiling in below the line of the pavement; then the value of the semi-prism as a light projector is entirely lost.

It will be seen also, on reference to the above diagrams, in Fig. 1 that the first row of semi-prisms obstructs the rays of light from each succeeding row, whereas in Fig. 2 the bulk of the rays of light are projected at such angles as to pass unobstructed into the room.

The correctness of these illustrations can be practically demonstrated to any architect desirous of testing them.

PRICE LISTS AND ESTIMATES ON APPLICATION TO

WILSON & CO., Bridge House, 181 Queen Victoria Street, London, E.C.

In conclusion, I can only hope that the appearance which Great Britain will present next year at Paris will warrant felicitations. Rumour has it that the large fees for space which the Mansion House Committee were compelled to charge has had a very depressing effect upon the number of the exhibitors, and that at least one important industry will be conspicuous by its absence. It seems quite certain that, at any rate in the area of space which it will occupy, the British court at Paris in 1889 will compare very unfavourably with the magnificent display organised by Sir P. Cunliffe Owen under the direction of the Prince of Wales in 1878.

#### A SPANISH RAILWAY.

THE Anglo-Spanish line from Zafra to Huelva has been opened, and, according to the *Times*, it has special importance for those interested in the success of English enterprise in Spain. It is an important trunk line, which has not merely been built by English capitalists, but which in part for some time past and now in its entirety will be worked on English principles. The undertaking is one of the first magnitude. The difficulties overcome in traversing at right angles the Sierra Aracena, a spur of the Sierra Morena, have been immense. Instead of traversing the Sierra superficially, the promoters have pierced it with tunnels, and deep precipitous cuttings have been made through the solid rock, of which six million cubic metres have been removed. Aerial bridges and viaducts span the rivers and the deep chasms, and a lofty embankment forms no inconsiderable section of the line. This railway, in the most unexpected manner, after crossing the inhospitable Sierra, opens up smiling, fertile valleys, whose fruits and wines have hitherto been shut out from the world. The owners of the mines of copper, silver, nickel, and lead, and quarries of marbles, rivalling those of Carrara for white and those of Algeria for coloured stone, will also now find an outlet for their productions, and these mines are already being developed in a manner more American than Spanish. The railway further places the province of Estremadura, the cereal granary of Spain, in direct communication with the heart of the Peninsula.

The line has taken seven years to construct, the work being carried on without any interruption, and in the tunnels

by day and night. Sixty-seven kilomètres on this side of the Sierra have been open for two years, and already yield for the traffic per kilomètre nearly double the average of that on other Spanish railways, the result being partly due to the cheap rates and frequent trains. Facilities for traffic are entirely ignored on other lines, and their mismanagement is a public scandal, which the present energetic Minister of Public Works is attempting to remove. Ten millions sterling of British capital are invested in this district. The Zafra railway has cost two and a-half millions, raising the total to twelve and a-half millions. Señor Canovas del Castillo in his inaugural speech did full justice to the good work accomplished by English enterprise, and his declaration that foreign capital in Spain was well employed, and that its employment deserved and would receive protection, elicited hearty applause from the large assembly which he addressed. The inauguration passed off without hitch or accident of any kind.

#### THE CARDIFF EXHIBITION.

HAVING spent a few days at the Cardiff Exhibition, we must say that few Exhibitions have struck us so forcibly for good arrangement, compactness, and variety of interest. The great part of the exhibits are local, and it reflects great credit on Cardiff that it can contribute so largely. The visitors so far have numbered about 150,000, and seem to have entered keenly into the merits of the various improvements, inventions, &c. We do not propose to go into details as to the exhibits in the present issue, but we may enumerate a few of the most prominent firms. Mr. Robert Adams exhibits his reversible safety securing window sashes, his unexcelled door springs, &c., under the supervision of his energetic manager, who is so well known to the frequenters of exhibitions. Messrs. Corfield & Morgan, Cardiff, have a splendid collection of marble mantelpieces, and a novelty in marble overmantels, which has an excellent effect; indeed, we have seen nothing to excel their exhibit. In bricks, the Cattybrook Brick Company, Limited, Bristol, exhibit every variety, the noticeable feature of which is their splendid terra-cotta colour and their peculiar smoothness. Mr. R. Scholefield of Leeds, has erected quite a brickmaking plant, illustrating the merits of his patent machinery, which insures both economy and efficiency. Messrs. Kotyra, Jouki & Co. have

Capable of the most artistic treatment

an interesting exhibit of electric bells. Messrs. Barstow & Sons, of Pontefract, filters which have recently been awarded the highest medal at the Brussels Exhibition. There is a local firm represented doing a good business in driving tube wells, viz., Messrs. H. H. Raynard & Co. We understand that the specimens here are capable of delivering 1,000 gallons of water per hour, but we shall refer more in detail to them in a subsequent notice. Mr. C. E. Gurnsey, of Bristol, sends an excellent variety of lamps and lanterns for street lighting, that are equal to anything we have seen in this way. The Cardiff Granite Company exhibit their improvements in this industry, which we shall refer to in a subsequent notice. Messrs. Cotterill Bros., Bristol, the well-known paperhangings manufacturers, are well represented by some very novel artistic designs. Messrs. F. Jones & Co., patentees of the silicate cotton, show its various applications as a fire preventative. Messrs. Thos. Baillie & Co. exhibit translucent enamelled glass, particulars of which we will reserve for a special notice. Messrs. Cameron, Amberg & Co., of London, have an excellent variety of their patent system of cabinet letter-files, &c. Messrs. King & Smith, Weedon, Northamptonshire, are *en evidence* with their well-known patent honeycomb wine-bin, which possesses advantages so obvious as to command success. That excellent stove, the "Nautilus," the patent of Mr. J. B. Petter, of Yeovil, is shown in different sizes. The mail-clad stove, adapted for churches, &c., is coated with mail, which retains the heat longer and distributes it more evenly. This is a recent patent of Mr. Petter's, and promises to be as well known as the "Nautilus."

# PRIVATE TURKISH BATH, WOLVERHAMPTON.

THE plan and description of Mr. S. T. Mander's private Turkish bath at Wightwick Manor, Wolverhampton, Messrs. Grayson & Ould, architects, Liverpool, will be of interest to many of our readers. The building, which is of brick, consists of three rooms—two hot-rooms and a cooling-room. The centre one answers as "tepidarium" and shampooing-room. Three rooms are sufficient, and answer all purposes for a private bath. The cavity in the walls is made use of for ventilating the bath, and is useful as a non-conductor from the colder air outside. The inside walls are of glazed bricks in various colours, designed in good taste. These walls form the best surface for hot-rooms; they are easily washed. The ceilings

are concrete, and the floor neatly tiled. The bath is effectually heated by Messrs. J. Constantine & Son's (Manchester) convoluted stove. The size of warm-air flue is 2 feet 9 inches.

The air to be heated is drawn from outside through flues of equal dimensions. With such provision for ventilation a rapid and constant change of air takes place, and all vitiated air and

THE "PERFECTUM."

# "PERFECTUM."

In London the above are kept in stock by Messrs. GEORGE WRIGHT & Co., 155 Queen Victoria Street, E.C., who will be pleased to show and explain them to Architects and Contractors.

On view at the Cardiff Exhibition, September and October, and at the Iron-monger's and Metal Trades Exhibition, London, November 12 to 24, 1888.

TELEGRAMS—"PERFECTUM," BOLTON.

The "Perfectum" will be exhibited in the Parkes Museum, London, and at the Glasgow Exhibition. Architects can have a Model Free of Cost on application.

# VOLUME XXXIX. OF THE ARCHITECT.

Handsomely bound in Cloth, Gilt Lettered. Price 12s. 6d.

Office: 175 Strand, London, W.C.

the effluvia thrown off by the bather is speedily carried away, and one of the chief desiderata of bathers secured much to their satisfaction. The English people are supposed to be rather slow to change habits or adopt those of other nations; but we seem to have jumped at and taken to the Turkish bath in a remarkably short time. We have not only taken to the system, but have used it freely, and we may take credit for having materially improved it in construction, and also developed a system of heating and ventilating it, which, based on sound scientific principles, can be relied upon to act with certainty.

#### THE INFLUENCE OF SUNLIGHT ON TREES.

IN the latest report of the head of the Forestry Department of the United States reference is made to the effect of light on the growth of various trees. It is well known, says Professor Fernow, that light is necessary for the development of chlorophyll, and, therefore, for the life of all green plants, and especially for that of trees. The heat alone which accompanies the light is not sufficient, although the relative influence of the light and the heat on the growth is still an open question, as well as the relative requirements in light of different species of trees. In the case of forest weeds, which in forestry serve as an indication of the amount of shade which the trees exert, and with that their capacity of impeding evaporation, some require full sunlight for their development, others are averse to a high degree of light. To this must be due the change in the plants of a district when its forests are removed. Then the amount of light or shade needed is modified by site. Where the sunlight is strong, in higher altitudes, drier climates, or where the growing season is longer, or there are more sunny days, some species will endure more shade. The flora of high altitudes in general requires light. Trees nearly always develop best, in other words make most wood, in the full enjoyment of light, but their capacity of developing under shade varies greatly. The yew will thrive in the densest shade, while a few years overtopping kills the larch; the beech will grow with considerable energy under partial shade, where the oak would only just keep alive, and the birch would die. When planted in moist places all species are less sensitive to the withdrawal of light. In the open, maples, elms, sycamores, and others grow well and make good shade trees; in a dense forest they thin-out and have but scanty foliage. Conifers,

such as spruces and firs, which preserve the foliage of several years, have perhaps the greatest capacity of growing under shade, and preserving their foliage in spite of the withdrawal of light. In America sufficient data to group the forest trees according to the amount of light required by them have not yet been collected, but rules based on experience have long been formed in Germany, where the behaviour of trees under different conditions of light has been carefully studied. It has been found, for instance, that on the same branch those leaves which are developed under the full influence of sunlight are not only larger and often tougher in texture and thicker, but that they have a larger number of stomata or breathing pores than those less exposed to light. The whole subject is one of the utmost importance in forestry, and observations and experiments are to be carried out in regard to it in the United States.

#### REGISTRATION OF PLUMBERS.

ON occasion of the opening of the New College, Newcastle-on-Tyne, by the Princess Louise, an inspection was made of the specimens of work by apprenticed plumbers. Mr. George Robson and Mr. T. S. Brown were presented to the Princess. The Master of the Plumbers Company, Mr. W. H. Bishop, explained to her Royal Highness the work which the company was undertaking in connection with the technical education of plumbers. Relative to the Worshipful Company of Plumbers and the special work in which it is engaged, he said the interest is owing to the survival of the principle of its laws, which date from its ordinances, Edward III., which virtually guide the action of the present company. The ordinances required that the skilled men of the craft should give close attention to the young men entering it, and that their ability should be duly certified. The only satisfactory security is that attaching to the employment of properly trained and certificated men. Efficient training is now dependent upon the system of technical education. The company is prominently identified with the practical development of that educational system by its co-operation in the formation of technical classes, where its principles and the practice of the trade were taught. The master desires by his presence to represent the union effected by the use of a common system between the plumbers of the north of England, the chief educational establishment of the district, the Durham College of Science, and the company

## £20 REWARD. FRAUDULENT SUBSTITUTION.

Having received complaints alleging the failure in certain cases of the Self-acting Air-Pump Ventilator, upon examination being made it was found in every instance that the Contractor had substituted, to secure a greater profit to himself, a cheap and inferior Ventilator resembling in outward appearance the Self-acting Air-Pump Ventilator, which had been specified to be used.

In one case, a Workhouse, as many as Forty Ventilators were found to have thus been fraudulently substituted, and which had to be replaced at the Contractor's cost by the Air-Pump Ventilator.

Any person giving information as to such Fraudulent Substitution as will secure a Conviction, will be paid the sum of

**TWENTY POUNDS.**

It is respectfully requested that in specifying the Ventilator, the words "Robert Boyle & Son's latest Improved Patent Self-acting Air-Pump Ventilator" be used.

EACH VENTILATOR HAS AFFIXED  
REGISTERED TITLE AND TRADE MARK,

TO IT THE ACCOMPANYING  
WITHOUT WHICH NONE ARE GENUINE.

OFFICE: 175 STRAND, LONDON, W.C.

whose centuries of existence are as full of tradition as they are of promise for the future. The development of the system will increase the demand for technical classes, therefore the opening of the College is happy in time as in other circumstances. The Corporations of Newcastle and Gateshead, as well as the plumbers of those towns, were among the first supporters of the movement for the registration of competent plumbers; and by the joint action of those bodies practical classes have been carried on during the past two years under the personal direction of a committee of plumbers and the gifted principal of the college. In historical interest this present occasion is exactly 200 years subsequent to the date of the coat-of-arms granted to the company in 1588 by Queen Elizabeth. Your Royal Highness will see the coat of arms in this frame, and there is a peculiar tie existing on this occasion, as the Recorder of Newcastle, W. Digby Seymour, Q.C., is one of the Wardens of the Worshipful Company of Plumbers, and upon his motion many of its most important steps have been taken.

### PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

#### APPLICATIONS FOR PATENTS.

- 15398. Henry George Planner, for "A disinfecting apparatus for waterclosets, urinals, drains, &c." October 26, 1888.
- 15420. Frederick Lamacraft, for "The self-hanging and fastening and easily removable window-sashes." October 26, 1888.
- 15441. Frederick Ransome, for "Improvements in furnaces for burning cement and like materials." October 26, 1888.
- 15461. David Burns and James Blyth Cairns, for "Improvements in apparatus for regulating and fixing fanlights, ventilators, casements, mirrors, and other articles of furniture moving on pivots or hinges." October 27, 1888.
- 15478. August Wittgeroth, for "Improvements in heating and ventilating apparatus." (Complete specification.) October 27, 1888.
- 15503. William Cussans, for "An improved safety bolt or

fastener for windows, doors, casements, &c." October 27, 1888.

15505. Joseph Harrison and John Edward Linsey, for "Improvements in drawing pens." October 27, 1888.

15568. Benjamin Richardson and Edward Dickinson, for "Improvements in guards for brickmaking machines." October 29, 1888.

15583. John Herbert Bewick, for "A draught or dust-stopper for the top and bottom of house-doors." October 30, 1888.

15586. Robert Bearpark Lyon, for "A machine for moulding bricks." October 30, 1888.

15601. Charles James Harcourt, for "Improvements in the manufacture of electric bell-push fittings." October 30, 1888.

15610. John Rothwell, for "A new or improved apparatus for ventilating and other purposes." October 30, 1888.

15620. William Phillips Thompson, for "Improvements in or relating to cocks, valves, taps, and the like." (Jean Cortella, Belgium.) October 30, 1888.

15650. Alfred James Clark, for "Improvements in fire-grates and stoves." October 30, 1888.

15668. William Smith, for "Improvements in, or connected with, wood-planing machines." October 31, 1888.

15725. Samuel Worsencroft, for "An improvement in cowls or ventilators." November 1, 1888.

15745. John Porter, for "Improvements in contrivances for effecting the escapement of smoke and preventing draughts in chimneys." November 1, 1888.

15754. Catherine Hubbocks, for "A drawing square, called the 'Paragon Square.'" November 1, 1888.

#### PROVISIONAL SPECIFICATIONS ACCEPTED.

12489. William Robert Gunn, for "An improved automatic arrangement for preventing draught and dust entering under or at the top of doors." August 30, 1888.

12491. Alfred Maconochie, for "An improved sheet or covering for water or other closets." August 30, 1888.

12540. John Mason, for "Improvements in skylights, ventilators and sidelights, by means of reversible weather bars." August 31, 1888.

13319. Arthur Greg (of the firm of James Chadwick & Brother), for "A new or improved self-acting machine for sawing timber and the like." September 15, 1888.

13393. Richard Hocking, for "Improved self-flushing apparatus for cleansing privies, sewers, and drains." September 17, 1888.

## GRUNDY'S PATENT WARM-AIR VENTILATING FIRE-GRATE.

The novelty, superiority, and advantage of this patent consist in the heating surface being greater than any other Fire-grate introduced to the public. It is very simple in construction, and is made in the form of a Stove, the back of which is semicircular in shape, with gills behind and smoke-nozzle on top, all cast in one piece. The same can be attached to any design of a Register or Stove front. It is very suitable for schools, class-rooms, waiting-rooms, hospitals, offices, dormitories, and dwelling-houses, from the cottage to the mansion. Design and specification post free on application.

#### TESTIMONIALS.

9 Victoria Chambers, Westminster, S.W.  
SIR,—I have much pleasure in testifying to the efficiency of your patent warm-air fire-grate. It has been very successful, and given every satisfaction where I have used it.

Yours, &c., JAMES WEIR, F.R.I.B.A.,  
8 John Street, Bedford Row, W.C.

To Mr. Grundy.  
From Hon. and Rev. G. G. C. TALBOT, M.A., Withington, Cheltenham.

DEAR SIR,—You will be gratified to hear that the school is completely warmed by your new grate. It is the most economical and efficient that I have ever seen.

Mr. John Grundy.

#### ACROSTIC.

Just listen, friends, to what folk say  
Of Grundy's patent warm-air grate,  
How with the fresh air channels they  
Not only warm, but ventilate.

Give wondrous heat, burn little coke,  
Require but slight attention paid,  
Unequal'd for consuming smoke,  
No better grates were ever made.  
Do try just one of Grundy's glo,  
You then will all its merits know.

#### APPLY TO

# The Architect.

## THE WEEK.

THE depth of the gratitude towards architects who have helped to bring about success was displayed in the ceremony at the closing of the Glasgow Exhibition on Monday. The President appeared to be generous in recognising all quarters from whence help came, but not a word was said about the man who designed the building in a way that enabled every object to appear in the most satisfactory manner, and who did not live to see the final triumph of the Exhibition for which he so loyally laboured. Nor were the exhibitors more grateful. We hope atonement may be offered by founding a professorship of architecture in Glasgow out of the weighty surplus, estimated at 40,000*l.* The receipts for admission amounted to 118,938*l.* 9*s.* In addition, the season tickets brought 43,716*l.* 4*s.* 6*d.*, making a total of 162,654*l.* 13*s.* 6*d.* The number of people who passed through the turnstiles was 5,748,379, being in excess of the Colonial Exhibition, which was 5,550,749, and of the Manchester Exhibition, which was 4,765,137.

A RULE ought to be made by architectural societies prohibiting the delivery of an address at a conversazione. The galleries of the Arts and Crafts Exhibition were used as a scene for a meeting of that kind on Tuesday by the Society of Architects; but when so much was to be seen, how could sufficient attention be given to Mr. SETH SMITH's address? With all its good sense, it helped to tantalise a great many who would have preferred to be elsewhere, although compelled by courtesy to serve as listeners. When the address was composed the place of delivery was probably unknown, otherwise there would be some relation between it and the contents of the Exhibition. The education of architects' pupils, compulsory examinations, improvements in construction, leaseholds, the rise in the price of materials, are all very important topics, but they could be treated with equal benefit in a different place, without oppressing ladies with "shop." There is a great want of brightness about architectural assemblies, and the Society of Architects would do well to depart from the jog-trot mode of combining business and pleasure. LORD WINCHILSEA returned the compliment for the visit he received at Kirby Hall by proposing a vote of thanks to the President.

MR. JUSTICE GRANTHAM's decision, in the case of *HARDING v. Guardians of the City of London Union*, has settled the question of the right of a building owner to pay a quantity surveyor out of the money due to a builder. Henceforth it will be useless, under such circumstances, for a builder and his representatives to demand money so paid. In the case before the Court the Official Receiver in the bankruptcy of a builder sought to get back a sum of 52*l.* 7*s.*, which had been paid by the Guardians to a surveyor for his bills of quantities. The case was complicated by the builder making over his rights to a third party who laid claim to the money. Afterwards the Official Receiver was made plaintiff in the proceedings, but as the judgment was in favour of the Guardians the estate will have to bear the costs.

THE inquiry into the causes of the collapse of the houses in Great Titchfield Street is exciting much interest among architects, engineers, and builders. There is nothing remarkable about the buildings, and as there was no difficulty to be overcome, the accident is more mysterious. The walls were of brick, and appear to be of good quality, and, indeed, accidents can rarely be ascribed entirely to bricks. The strength and quality of the ironwork will obtain necessarily much attention before the coroner, and the evidence of experts will be required to satisfy the public. When the house fell in the Haymarket it was supposed by some experts that the ground beneath the foundations must have slipped or shifted. Whether a similar explanation can be offered in this case remains to be

seen. At present there is only one certainty, that the men who have most at stake in the issue of the inquiry are in the dark about the cause of the collapse.

THE Society of Arts has never put forth a better programme than the one for the coming session. The meetings commence on the 28th inst., and for the first the Society has been fortunate in securing Colonel GOURAUD to explain the new phonograph, about which everybody is talking. At the second meeting the no less interesting "Graphophone" will be the subject. "Explosives" and "Standards of Light" will be the subjects of the remaining lectures before Christmas. Among the lectures for next year will be the following:—"Manufacture of Sèvres Porcelain," by M. GARNIER, of the Sèvres factory, and one of the authors of the South Kensington Handbook on French pottery. Mr. B. BAKER will describe the Forth Bridge, of which he is one of the engineers; and Colonel HOZIER's paper will give a chance to discuss the *pros* and *cons* of the Channel Tunnel. The meetings of the Applied Art Section will not begin until January 22. The Cantor lectures will consist of six courses. Captain ABNEY will take "Light and Colour"; Mr. A. S. COLE, "Egyptian Tapestry"; Mr. WALTER CRANE, "The Decoration and Illustration of Books"; Mr. W. J. LINTON, who at one time held the first place in his art, will lecture on "Wood Engraving." The scientific subjects treated will be "Instruments for the Measurement of Heat," by Mr. C. V. BOYS, and "Heat Engines," by Mr. GRAHAM HARRIS.

A MEETING of the Royal Scottish Academy was held on Wednesday, when Mr. GEORGE OGILVIE REID (Edinburgh), Mr. THOMAS SCOTT (Edinburgh), and Mr. JAMES GUTHRIE (Glasgow) were elected Associates of the Academy.

LORD ARMSTRONG has shown his interest in the Benevolent Fund of the Institution of Civil Engineers by offering to contribute any sum not exceeding 5,000*l.*, provided the members will raise a similar amount. It is to be regretted that nobody is in a position to render a corresponding service to the Architects' Benevolent Society.

It is intended to amalgamate the various architectural societies of the United States with the New York Society known as the American Institute of Architects, each, however, preserving its independence. There are to be three great sections comprising all the States, and these are to be divided into State Associations, or chapters, which may be subdivided into lodges, according to circumstances. All divisions and subdivisions are to be free to make laws and regulations for their own government, excepting only that the standard of admission to membership must be at least as high as that fixed by the constitution of the Institute.

DURING the reign of the late Emperor of the FRENCH there were only two salons in Paris where men of letters were likely to be met. One belonged to the Princess MATHILDE, to whom arts and letters were indebted in those days; and over the second, which was in a wonderful house in the Champs Elysées, "LA PAÏVA" presided. There was jealousy between the two patronesses, and it is upon record that on one occasion the Princess expressed her anger openly, when it was said that M. HÉBERT accepted a commission from the "drôlesse," who believed that everything was gainable by a strong will, and that failures could be settled by an overdose of chloroform. The PAÏVA mansion did not display refined taste, but in furnishing and decoration it was the most expensive in all Paris. Everything was heavy and ostentatious. Some of the best painters in Paris gave their help to make the walls and ceilings a town talk. The salon and smoking-room were undertaken by M. LOUIS REY, and the former became a "vision of fair women," with LA PAÏVA as a sort of climax. PAUL BAUDRY undertook the ceiling, and represented VENUS looking down on her worshippers. M. LOUIS REY has just died in Paris, and the mention of his name will recall the strange story of the house where was his principal work. He painted several buildings in addition, but of late years his style was out of fashion.

## THE ARTS AND CRAFTS EXHIBITION.—II.

THE first work which will obtain the attention of the visitor in the Exhibition is likely to be the "Brass and copper fountain" designed by Mr. BENSON. That copper is coming into fashion will be evident from the windows of the large ironmongers' shops in London. There is no reason why it should not be utilised for part of a fountain. Mr. BENSON has adopted a form that is simple—a basin with good mouldings, and without any of the heaviness which is common with fountains. It would be well adapted for a hall. The parts of the large iron gates, by Messrs. ROBINSON & ROBSON, which are most successful are the constructive pieces, the curved lines being graceful. The larger leaves are stiff and characterless, whilst the roses in the central openings appear unconnected with the general design. In the font cover carved by Mr. KNOX from a design by Mr. SOMERS CLARKE, the error is avoided of giving detail in the crockets, and the figures in the interior forming a complex group are well rendered. A drawing and a panel of the pulpit in St. Martin's Church, Brighton, designed by Mr. CLARKE and Mr. MICKLETHWAITE, suggest an important work which recalls the Sakramentshäuschen of Nuremberg. The two works represent Gothic art in the Exhibition, and somehow the contrast offered by them to the remainder of the objects suggests that Mediævalism and freedom have little in common.

If there are manufacturers who conceal the existence of the men who aid them, it cannot be said that the practice is general. Of late years several firms appear to consider that one of the best ways of success is to announce the names of their designers. Messrs. MINTON have three cases of pottery, with about thirty examples, on a scale which admits of delicacy of touch, and anyone who is curious can see the names of the artists who painted or decorated the vases and plates. French influence is visible, and the collection would sustain a comparison with the best French work. Every specimen merits attention. The *pâte sur pâte* of A. MORGAN, as seen in No. 346, the Parian ewer, No. 358, and the china vases by JESSIE POPE, the dessert-plates by L. BIRKS, the vases by A. BOULLEMIER, may be cited as especially successful. The *Amazon*, by HENRY ASTON, is a well-known statuette, one of the many compositions derived from the group of KISS. M. SOLON's name is associated with the firm, but he has before now surpassed his two slabs. Can anyone suppose that it would be possible to produce pottery of the class shown in the three cases without the resources which can only be found in an establishment like Messrs. MINTON'S? In other trades there is a similar necessity for an organisation on a large scale, if even small works are to be satisfactory. That being so, it seems unwise to induce men to imagine that they can be successful if they work single-handed. Messrs. MINTON, and the other manufacturers who exhibit, are representatives of "the modern industrial system" which is so obnoxious to the Arts and Crafts Society, yet such work as theirs is obtainable in no other way. Tiles and some lustre pottery are the works which Messrs. MAW & Co. exhibit, and they also need the modern industrial system. The designer has an important share in their preparation, but much depends on men who must remain unrecorded in catalogues. Nine or ten designers' work is to be seen in Messrs. MAW'S stands, and there is a variety of styles. Mr. WALTER CRANE has tiles with figure subjects, which are as simple in design as if the drawings were intended to illustrate a child's book, and the treatment corresponds with the subject. Mr. DAY is elaborate, but recognises the virtue of flatness. Mr. TEMPLE, Mr. JOHNSON, Mr. LODGE, and others, represent different styles, for whatever may be the defects of the manufacturing system, a lack of variety is not one of them.

The formation of a company to work the "cloisonné mosaic" is evidence of the necessity of the co-operation of many if some kinds of work are to be developed. The large jars which are covered with the material are rather commonplace in form, and it would be easier to obtain better patterns; but there can be no question of the excellence of the new cloisonné mosaic, or of its applicability to curved as well as to flat surfaces. It appears in the Exhibition in several forms. An example of "opus sectile

and mosaic"—a figure of *St. Gabriel*, with pink wings designed by Mr. J. W. BROWN, and exhibited by Messrs. POWELL & SONS—is very brilliant in colour, and the execution is adapted for a panel that will be fixed close to the eye.

There are many examples of metalwork in the entrance hall. The most important, according to the money standard, is the waist-belt of wrought gold, designed by Mr. CARTER for Messrs. HUNT & ROSKELL. It consists of a series of panels filled with a number of small figures in relief; but the artist seems to have had some old engravings before him when designing them. At first sight the belt would not be taken for an original, and to some that quality will be its highest praise. The two nude figures of women which form the handles of Mr. SIMONDS'S "loving cup" are well-modelled; but surely it is false art to introduce the figure in that way. Again, what connection can exist between them with the serpents which retain them with a feast? The "dance name and number holder," by Mr. REYNOLDS-STEPHENS, with figures in low relief—a Greek boy playing while a girl dances—is evidence of what can be made out of a commonplace thing by an artist. Many ambitious pieces of sculpture in relief have less spirit than this small plate of metal. Delicate work of an ornamental kind will be found in finger-plates and lock furniture by Mr. T. R. SPENCE, who displays versatility as well as skill in designing for works in different materials. The Toynbee Hall School and Guild of Handicraft send several examples of *repoussé* brass, some of them rather ambitious in design. It is only a master who should attempt to represent the features of a face by the process. Mr. WALTER CRANE is an able artist, but he completely failed when, in No. 295, he attempted to represent the face of PHŒBUS. In the dish, which is ornamented with fish, he is successful, and the work suggests the limitations for men who are less expert. The specimens by Mr. STEBBINGS, of Renaissance ornament, have more freedom of treatment than the majority of the experiments in *repoussé*. In wrought-iron the bracket for gas and the large bracket for lamps of floral type, designed by Mr. SEDDING, take first place. It is gratifying to find a piece of work which does not depend upon spirals for its effect. The altar cross, by the same designer, is of plain brass, the arms and top ending in crowns. Messrs. GODFREY & SON'S brasswork, if original, has at least the characteristics of German work. Messrs. ELGOOD introduce the artichoke for the decoration of one of their *repoussé* plates, which is novel. There are several lamps in brass and copper. Mr. CRANE, it is needless to say, has one, and another is by Mr. HARDY.

The copy in tapestry of Mr. BONE'S design, *Alfred in the Danish Camp*, will suggest that the failure of the Windsor Tapestry Works did not arise from defects in the weaving. The original is closely followed (the hands, as is not uncommon, being the weak parts), and the colours are kept low. The care of the workmen is unquestionable. Many fine pieces of embroidery are in the hall. The border of an alb in Limerick lace, although only on a net body, is interesting; but the wonderful cherubs' heads recall Mr. RUSKIN'S description of the Irish scribe who contrived to leave out the mouth when he was drawing a face. Here, we suppose, the lines are intended for a mouth, but they are in the wrong place. No one will wonder at divagations among the lace-makers, since they are under the instruction of the South Kensington authorities, who take a good deal of credit for their success.

The next gallery contains examples of pottery, wall-papers, embroidery, furniture, and bookbinding. Mr. DE MORGAN has not had before such an opportunity for the display of his successes as a potter. A chimney-piece designed by Mr. RICARDO serves not only as a support for vases and plates, but also allows the tiles to be shown around the grate and as a hearth. Mr. DE MORGAN'S success was at first in his lustres, but now his skill is seen in most branches of the potter's art. The large framed panel of tiles stretching from ground to ceiling, in which a symmetrical arrangement of peacocks is the chief feature, would be considered a *chef-d'œuvre* by the Persians. The big vase is a fine piece of throwing, but the handles might have been copied from an example in metal. When it is remembered that Mr. DE MORGAN'S experiments began a few years ago, his collection is most remarkable, and

should be a lesson to people who are fainthearted about the prospects of industrialism.

The committee of the Exhibition announce "that some leading firms in the supply of decoration have shown no disposition to exhibit under the condition that the names of the actual executants of any work shall be published." From an accusation of that kind Messrs. WOOLLAMS & Co. and Messrs. JEFFREY & Co. are free. Both firms give prominence to the names of their designers, and endeavour to associate them with the titles given to the patterns. The specimens shown in the Exhibition exemplify the perfection which is now reached in wall-papers, owing to the liberality of the manufacturers and the emulation which must arise when several artists are engaged in a common purpose. It can be said without exaggeration that out of England it would be impossible to see equal merit in this class of work. If, therefore, the industrial system can be successful and satisfactory to artists as it is carried out by Messrs. JEFFREYS and Messrs. WOOLLAMS, may it not be equally successful whenever similar enterprise and love of art are brought together?

Near the papers are pieces of cretonnes, designed by Mr. DAY, in simple patterns that are suggestive of brushwork. A cotton hanging with birds, designed by Mr. LATTIMER, is clever and inexpensive. Mr. WARDLE has several textiles in cretonnes, silks, velvets, &c., but chief among this class of work is the silk damask exhibited by Messrs. MORRIS & Co. The patterns by Mr. WILLIAM MORRIS have the largeness of style that is seen in Venetian work, and are very different from the "sprigs" and stripes which are supposed to be most suitable for textiles of all kinds. They illustrate Mr. MORRIS's principle, that large patterns if properly designed are more restful to the eye than small ones. The Arras tapestry is also successful, and the design, *The Wise Men's Offering*, by Mr. BURNE-JONES, for reproduction, is worth notice as a new version of the event. It must be said that the furniture is not the most satisfactory part of Messrs. MORRIS's collection. There is no fault apparent in the workmanship, but the designer would seem to have been hampered in his efforts at novelty by the necessity of preserving an eighteenth-century character for the pieces.

The examples of bookbinding are interesting. The Celtic ornament which Mr. COFFEY introduces on the covers of the two volumes of FERGUSSON's poems are appropriate, and well arranged, but what fitness can the ornament have for a book containing Sir JOHN MILLAIS's attempts to illustrate the Parables? Mr. MOYR SMITH makes a very pleasing cover by depending mainly on gilt lines, and it is the only example of the artist's work in the Exhibition. ROSSETTI's plan of massing gold ornament on a part of the cover has been followed by Mr. DAY. But it is useless to expend much trouble on cloth covers, when the material itself not only fades, but through the chemical covering acts upon the gilding. Any of the books published by CHARLES KNIGHT, which were the first to be covered with cloth, still keep their colour, while modern books after a year or two become shabby. One case contains several illuminated manuscripts in which Mr. MORRIS, Mr. BURNE-JONES, and other artists, exemplify the advantages of a division of labour in a manner that would gratify the most rigid opponents of the principle.

This gallery is rich in decorative needlework, but as a rule the designs are supplied to the ladies. If that sort of decoration is needed, we need not go abroad to find a supply. Shops are now displaying gaudy Japanese embroidery in screens and hangings which, to the majority of people, are perfection. Happily there is no sign of imitation of the fashion in the needlework of the Exhibition.

The Century Guild of Artists furnish a variety of their works in metal, wood, painting, &c., to this gallery. The cottage piano, designed by Mr. MACKMURDO, of which the back is visible, is a departure from the cumbersome model so esteemed throughout the world. The stencilling designed by Mr. A. HEATON is also worth imitation. The photographs and drawings of metalwork at Haileybury College, by Mr. REGINALD BLOMFIELD, show an original sort of treatment, and equal vigour and spirit can be seen in the grate, lantern, and other works, by the architect, which are in the gallery. Metalwork needs the utmost attention in

England at the present time, for the Germans have taken it up with great energy.

The question of price is always suggested in an exhibition, but in this case it is better to be ignored. The patrons of the Society will not, we hope, ever ask whether it is possible to obtain equal perfection in form for less money. Everyone knows that individual handiwork is more expensive than what is produced by the combined action of hands and machinery. As regards price, a man can never hope to succeed in competition with a machine. A manufacturer who seeks to obtain the support of the public in the ordinary way need not therefore feel any jealousy when he visits the Exhibition, for he will at once recognise that the objects before him must be produced and purchased under conditions which cannot exist in his works or shop. He may even be doubtful whether many of the exhibits were not produced solely for the gratification of the "craftsmen," and without any thought of sale.

But if questions of price are not to be considered, we may at least be allowed to ask (assuming, for the moment, that the makers are genuine representatives of trade in every case) whether the Exhibition realises what is, or rather was, meant by craftsmanship? The artificers who lived long ago, and to whom we apply the title of craftsmen, were expected to be competent to design the things which were to be made by their own hands, with the aid of their assistants and apprentices. It was the creation in the mind before the material was taken in hand which distinguished the craftsman from the mechanic:—

Den schlechten Mann muss man verachten,  
Der nie bedacht, was er vollbringt.  
Das ist's ja, was den Menschen zieret,  
Und dazu ward ihm der Verstand,  
Dass er im innern Herzen spüret,  
Was er erschafft mit seiner Hand.

To be received as a member of a craft, it was necessary for a candidate to produce a piece of work which was entirely his own. He was not given a drawing and told to follow it, as would be the case now in so many trades. Occasionally a painter or a sculptor might supply a design for a work in gold or silver; but, as a rule, each craft tried to be independent of external help. Indeed, the jealousy of trades would be an obstacle to much co-operation between them. The limits for action were prescribed by law, and it is known that a sculptor was not allowed to meddle with the constructive part of a work, such as a tabernacle or an altar in a church, for which he obtained a commission, but was restricted to the ornamentation. If, therefore, the existing system of production is to be abandoned, why should we not return to the practice of the veritable craftsmen? There are no precedents of any account which justify such a combination of artist and workman as is seen in the Exhibition now held in Regent Street. It is a departure from the old ways in common with division of labour, of which, indeed, it is an example. If the workman is not his own designer, what security can we have that he is satisfied with his work? Where is the chance for any individuality with such precise drawings as those which are seen in the Exhibition, and which in some cases appear to be displayed in order to show the fidelity of the copy, and therefore to assert the claims of the designer for the credit of the work? There is no difficulty with drawings of that class in obtaining copies by means of division of labour and machinery, and he would be a brave man who would say they had less correspondence with the design than the copies made solely by hand. The fact is this reform, like all which preceded it, bears the stamp of the reformers. It is a project of artists who are not craftsmen, rather than of craftsmen who are artists. It can be taken as no more than an intermediate step in the movement. If we must have craftsmen, it will be impossible to withhold the power of creation from them. Mere copying, such as is seen throughout the Exhibition, can be as well done under the present system. If, therefore, the artists of the Society are eager to bring about a revival of craftsmanship, they will have to be self-sacrificing, and enable the workman to be independent of designers, if they cannot emancipate him from the capitalists. If, however, the Exhibition simply represents an agreeable co-operation between artists and amateur metal-workers, carvers, embroiderers, &c., it is not then necessary to go back to the practice of the veritable craftsmen.

## THE ARCHITECTURAL ASSOCIATION.

A PAPER on "Victoria and Elizabeth" was read by Mr. J. A. Gotch at the last meeting of the Association, as follows:—

In traversing this beautiful country of England with a view to examine its architectural remains, the two objects that we look for wherever we go are the Gothic church and the Elizabethan manor-house. I am not altogether sure, indeed, that with many of us the Elizabethan manor-house does not attract more attention than the Gothic church. How far this would have pleased or shocked our fathers in the profession it would be useless to inquire. Fashion sways our clients as it sways the hatter's customers. These will accept a wider or a narrower brim even as they are persuaded thereto by the young man behind the counter, and as his choice agrees with what they can recollect seeing in fashionable places. Those will accept a pointed or a round arch according to the dictum of their architect, so long as it is not at variance with what their neighbours are accepting on all sides. But each and all desire the cheapest of its kind, and are highly gratified at obtaining much show for little money.

Twenty or thirty years ago the pointed arch and its accompanying features were the only acceptable wares. Accordingly, to look at work less ancient than the thirteenth century was a grievous waste of time, not to say the mark of a dissolute mind. Now, however, the partakers of our annual excursion, though quite prepared to accord its full archaeological value to the thirteenth century, seek their inspiration for the nineteenth from work dating about half-way between the two, namely, from the times of Elizabeth and James. The reason of this is not far to seek. We are gradually awakening to the fact that forms and features which satisfied the equations that the Middle Ages had to solve do not satisfy those presented to us five or six centuries later. In ecclesiastical architecture, it is true, those forms and features are still not out of place. But ecclesiastical architecture is demanded by a select few. Domestic architecture is sought for by the million; and in the domestic architecture of Elizabeth and James is to be found much that offers clues and hints towards solving the problems of to-day. Apart from this practical reason for the change of taste, there is what we may call the historical reason. The sixteenth century marks sharply and decisively a complete change in men's habits of thought. With the Cecils and the Hattons, and the innumerable builders of mansions under Elizabeth, we have much in common; their ways are, many of them, our ways, and their thoughts our thoughts. But what have you and I to do with the celestial hierarchy that adorns the west front of Wells Cathedral, or with St. Edmund, king and martyr, whose severed head was miraculously joined to his body after death, and whose corpse thus supernaturally "restored" was the sole and sufficient cause of the erection of the enormous Abbey at Bury St. Edmunds? Or what with the sacred thorn that for centuries was the mainstay and support of the magnificent Abbey of Glastonbury? You and I, at any rate, are architects, and we love to know of these things, and some of us from loving to know of them come to love the things themselves, and even perhaps to feel towards the celestial hierarchy, and St. Edmund king and martyr, and the sacred thorn, some of the reverence which filled the minds of men six centuries ago. But then we are architects, and our sympathies are largely with the past. How is it with the pushing men of business with whom the world is peopled? Like Gallio, they care for none of these things.

But they do care for comfortable homes, for handsome houses, for labour-saving appliances, and for all the conveniences which modern progress affords; and from their architects they expect, first of all, these material things, and they sympathise but little with any desire that their architects may have to work in some particular style which prevailed when the fortress still left its trace upon the dwelling-house, when security was preferred to light and cleanliness, and when the quantity of the meat was of more importance than the quality of the cooking or the convenience in cooking it. It is not surprising, therefore, that the taste for Gothic houses was shortlived. Their pointed windows, however successful on the outside, were failures on the inside, obstructing the light where it was most wanted, and putting the upholsterer at his wit's end how to fix his blinds and curtains. Their wide-open fires were liable to smoke, were costly to feed, and warmed the chimneys where the family did not sit, in preference to the rooms where they did. The stained and varnished woodwork and the indecorous display of naked construction produced a feeling of chilliness and discomfort. After all, the most blameless life will not bear to have the whole of its motives exposed; the most beautiful bones are better for a covering of flesh. And so the desire for bare Gothic declined, and attention was diverted, with better prospect of success, to the great house-building epoch of Elizabeth. That period and the one in which we ourselves live are unrivalled for the amount of building which marks them. The building trade at the present time is one of

the largest interests in the country. The ever-increasing numbers of our own Association are themselves a proof of the amount of work that is being done in bricks and mortar. The innumerable illustrations which appear week by week in our excellent building journals, faintly suggest the amount and the variety of the work undertaken by the architects of Victoria's time. But we have to go back to Elizabeth's days to find anything like the same amount of general activity, though even then it was but as a placid lake compared to the stormy ocean. There was, however, hardly a squire then who did not either rebuild his house or materially modify it, while most of the nobles and nearly all the high functionaries of the Court erected mansions which to this day are, such as remain to us, models of stately design and magnificent taste.

To name only a few. There was the great Lord Burghley, who built Burghley House and Theobalds; there was Sir Christopher Hatton, who built Holdenby and enlarged Kirby; the Earl of Dorset, Lord High Treasurer, who built Buckhurst; the Earl of Suffolk, another Lord Treasurer, who built Audley End; Lord Robert Cecil, who built Hatfield; Sir Thomas Heneage, Treasurer of the Queen's Chamber, who lived at Copt Hall; Sir Percival Hart, Chief Sewer and Knight Harbinger to Queen Elizabeth; Sir Thos. Lake; and Sir George Coppin, Clerk of the Crown to James I. Besides these, who were in some way attached to the Court, and probably made the money there which enabled them to erect such noble houses—which were always, in their letters to each other, built solely in order to entertain Her Majesty in a suitable manner; besides these there were great noblemen like the Duke of Buckingham, who built Burley-on-the-Hill, and wealthy gentlemen like Sir Francis Willoughby, who built Wollaton, and Sir Walter Covert, who built Slangham Place, in Sussex. These are only a few of the great building owners of the time, only a small selection from the army of clients who were willing to spend half their fortunes in obtaining houses with all the stately apartments and the conveniences which the change of manners then rendered necessary. These men it was who inaugurated a new era in architecture, whose habits led them to require a new type of dwelling, and whose tastes demanded magnificence and display. They are sharply marked off from their predecessors, who were content to lurk in dark places, if sufficiently strong, and it is because they were men of so much wider ideas that we find it worth while to study their houses closely to-day. But though Elizabeth's days are more suitable sources of inspiration to us than the earlier times of unalloyed Gothic, far be it from me to advocate blind copyism for the architect, or to recommend a client to build himself a house strictly after the fashion of those built—as Evelyn phrased it of Kirby in the middle of the seventeenth century—*à la moderne*. Not at all. Mere copyism is the resource of the feeble; but, on the other hand, there is every reason why we should profit by the ideas, the successes, and more especially the failures of those who have gone before us. And for that reason it seems to me that an examination of the work of Elizabeth's time in the light of these days of Victoria will not be out of place.

Now, to begin with, of all the thirteen houses which have just been named, how many have come down to us? Only Burghley and Kirby, Audley End and Hatfield and Wollaton. Theobalds is gone completely, and so are the houses of Sir Thomas Heneage, Sir Percival Hart, Sir Thomas Lake, and Sir George Coppin. Of Holdenby, little but the memory remains. Slangham Place is reduced to a few columns and arches, and the grass-grown foundations of its extensive walls. Burley-on-the-Hill has been replaced by a great Palladian structure. So far as we know, they have not been destroyed by fire, or by any hostile agency, but they have gone to decay because no one was found to preserve them. And what of those which have survived? Kirby has been deserted for more comfortable houses; Audley End has been shorn of two-thirds of its extent; Burghley and Hatfield and Wollaton retain little of their original arrangement beyond the shell. The dwellings which suited our forefathers of Elizabeth's time do not suit us in Victoria's.

It is the same wherever we go. If we find an Elizabethan house occupied, either some radical alteration has been made, to the detriment of the architectural harmony, or else the inhabitants put up with manifold inconveniences rather than disturb the ancient order of things, which has served many generations of their predecessors. One of the most obvious drawbacks of the Elizabethan plan is the number of thoroughfare rooms. Burghley House has been helped by building a corridor round the courtyard. At Canon's Ashby, for want of some such addition, you have, from a considerable number of bedrooms, the choice of two ways to get to the breakfast-room. One is through the drawing-room, and down the main staircase; the other is down a subsidiary staircase and across the open courtyard. At Kirby the same difficulty was present, and before that house can be inhabited again that difficulty must be surmounted. A corridor here would be ruin to the beauty of the courtyard; while to roof the courtyard in, and to exclude

the sunshine from playing amid the badges of the Staffords and the long lines of swelling fruit, and to prevent the shadows from creeping across the grey and golden walls, marking from day to day "Time's thievish progress to eternity"—this might make Kirby habitable, but it would be a Kirby with half its poetry gone.

The fact is, these large houses were built for entertaining guests rather than as homes for their owners. The long rows of small rooms arranged round a courtyard were separate groups of apartments, self-contained, and designed to accommodate visitors and their servants in the same way that each undergraduate has his separate establishment at college. One of these groups is designed to include a bedroom, a reception-room, a servants' room, and a room for "wood, coal, and privy." There were certain larger rooms where the guests assembled together, such as the hall or the gallery, and to reach these the courtyard probably had to be traversed, just as to-day it has to be traversed by undergraduates for the sacred ceremony of dining. But in Elizabeth's days people seem to have cared less for the weather than we do; though, as rain would wet as much then as it does now, the gay gallants must have grudged exposing their finery to a sharp shower; and if they did get damp there would have been amid the brilliant assembly much the same kind of stuffy odour as pervades in our own times an omnibus on a wet day.

In the present day our habits are different. We do not entertain on the same sumptuous scale; a separate suite of rooms for every guest is not expected; people like to get to their rooms under cover, and would as soon thank you to put them up at a neighbouring inn as to ask them to walk across a wet court in evening dress. We find in these days that it tends to the easier and better work of the house to get all the bedrooms upstairs and the reception-rooms on the ground floor. There would therefore be no room for Lord Burghley's commendation of Holdenby, in that it had so fine an ascent from the hall to the great chamber. One of the governing features of an Elizabethan house we entirely omit from our designs—the long gallery. Almost all the old ceremonial is gone. Along with the gorgeous dresses went the stately manners, and the necessity for the stage whereon to display stately manners and gorgeous dresses. We look for large and lofty rooms now, because in themselves they are handsome and imposing, and not because they are picturesque backgrounds to our noble selves. We seek for comfort, not pageantry. And for that reason we no longer hanker after brilliant processions from the hall to the great chamber, winding up the broad staircase, where rows of quaint animals in all the attenuation and lissomeness of thorough heraldic "condition" gaze proudly over the heads of the guests, unmindful of all but the sacred family arms which they support. Not at all: we care for nothing of this; we prefer going up in a lift.

But the smaller houses, such as were designed for Sir George Coppin, or Sir Percival Hart, or Sir Thomas Lake, in London, were much more compact, and were tolerably convenient. But it is obvious even in them that expense was but little studied. If there was less money to spend, the house was made smaller, but no pains seem to have been taken to contrive economical plans. All those ancient buildings must have cubed out at a terrible figure. Everybody concerned seems to have agreed that one of the first things to be secured was a handsome building. The idea of getting the house comfortable inside, and leaving the outside to take care of itself, with strict orders to spend no money on show, which is a not infrequent instruction to us, does not seem to have occurred to clients in those days. They were quite content to let the architect have his way, and he went on the principle of making his clients adapt their wants to his architecture, rather than that of adapting his architecture to their wants. There is no doubt that his method was the easiest, and produced the most stately buildings, but our way is the best, and it is for us to solve the problem how to combine attention to all modern requirements with a handling of materials that shall produce fine architecture. Our task is by far the more difficult, and the time given to do it is generally of the shortest; so let not these things be forgotten when critics abuse the architecture of the nineteenth century. The method of the Elizabethan architect was simple enough. He ascertained approximately the accommodation required by his client; he found that he wanted a certain type of house, and away he went. The plan, perhaps, worked out so that there was a room or two more than the number asked for. A very simple matter; he just labelled them "waste," and the client had to pay for their erection; and the client's grandchildren, probably, paid for their pulling down.

Symmetry was another great solvent of those days: it simplified matters wonderfully, since it was accepted by all alike as indispensable. There was no need to adjust the sizes of the rooms to their various purposes, or to study the best positions for the windows and fireplaces. A start was made probably with the hall and the adjacent rooms; the position of the kitchen in relation to these was usually carefully considered, provision was made for the longest possible gallery, and the

rest was left to take care of itself. If it did not happen to work out quite happily for the best arrangement of some of the rooms, if the doors and windows quarrelled with the fireplace, or if the larder found itself possessed of a great bay window, nobody minded, for symmetry demanded it, and this excuse satisfied everybody. In the present day it is otherwise. Not only do we have to be very careful how we plan our buildings—so that not only our client and his wife are satisfied, but also his ox and his ass, and everything that is his—but as every foot of material is reckoned up beforehand, we have to be particular not to put in too many of them. Our predecessors had a freer hand; the masses of masonry in some of their chimneys would almost suffice to concrete the whole of the foundations; and yet amid those masses are generally to be found very delightful cupboards, the absence of which is the despair of the modern housewife. The wasteful planning of those times, at all events, carried some compensation with it.

Then, again, the great question of sanitation had not yet arisen. To-day we are slaves of the soil-pipe. That unsightly talisman has to be hidden as far as may be; and in the effort to hide it we make the whole house revolve round the small apartment which it safeguards. Not so the architect of Elizabeth's days. He was lavish in his supply of such apartments. Generally each suite of rooms had one. If it could conveniently be placed next to an outer wall, it was. If not, any other place was suitable. Sometimes it led directly out of the winter parlour, sometimes it was in a passage, sometimes in the middle of the house. Sometimes, but not often, it projected from the side in a manner almost modern, but, as a rule, the situations chosen for it are truly astonishing; and it is a matter of wonder whether our ancestors had any noses to offend or any blood to poison.

It has already been pointed out that particular care was bestowed upon the position of the kitchen; indeed, this is done to the exclusion of the consideration whether the servants overlooked the precincts devoted more especially to the family. This is a factor which played no part in designing a house in Elizabeth's days. A room was a room, no matter what its destination. Its windows ranged with the others, and were as good; so that, to look at the house from the outside, it appeared equally imposing from all points of view. This does not suit modern views at all. They demand that the servants' department shall be quite separate from the family's; and, as money must be saved somewhere, it had better be in the servants' offices, which need not be nearly so expensively finished outside as the rest of the house. At once, therefore, we have a back to the house—a large part of the building which has to be subordinated to the rest, which must be differently treated. This necessity alone is a factor which widely divides our ways from those of Elizabeth's time.

So, too, in the treatment of the elevation. In the old days they thought nothing of putting in numberless sham windows. The most picturesque side of Cobham Hall is riddled with sham windows, put there for effect merely, glazed to resemble their *bond-fide* neighbours, but built up at the back from the time of their erection. At Kirby, too, on one side of the entrance are the noble windows of the lofty hall, 20 feet high or more; on the other are a like number of noble windows, 20 feet high or more, but a close inspection shows that a floor goes right across the middle of them. In so far as their noble height is concerned they are shams. We cannot do that now, nor anything like it. Nor need we be anxious to make our chimneys look like coupled columns, nor to set great heraldic creatures climbing about the stonework, nor to do many other of the things which our ancestors did, but which, being done, we do not wish to see undone. These things, from which our sober judgment revolts, we can avoid, and yet find much to help us in the manner in which stone and brick and wood were wrought in those days.

But who was responsible for these buildings? That is a question not yet satisfactorily settled. That there was anything like the autocratic and all-accomplished architect of our times I do not believe, who to-day designs his client a sideboard, to-morrow arranges his drains, and next week commences a stained-glass window to his memory. Things were much simpler in those days, and the various branches of the business of housebuilding were under the special care of separate men who may—indeed must—have been amenable to a central authority, but who certainly did not look to him for every morsel of design and instruction.

In the building of Cobham Hall, for instance, we find that one R. Williams, who was probably the clerk of the works, writes to Lord Cobham as follows:—"We have bargained with Giles de Whitt for making two chimneypieces for the two chambers next to your new chapel. He demands 65*l.* for both. I will not give above 50*l.*, and he will accept it in the end rather than fail." And later we find the same correspondent urging his lordship to "resolve what and how much you are pleased to have done by Giles de Whitt, either upon some new chimneypiece, or upon my lord your father's tomb, that the poor man have some work to get wherewithal to maintain and

sustain himself." No doubt Giles de Whitt designed these chimneypieces as well as made them, and, to judge from the different character of design in stone and plaster and wood, no doubt the masons designed their own carving and the plasterers their own ceilings and the joiners their own panelling, for the hand was not yet divorced from the mind. To read the letters relating to the building of Hatfield gives one the same impression. The only agents who appear are the clerk of the works and the foremen, or the surveyors who are sent down to ascertain in what state the buildings are, and why the cost so much exceeds the estimate. There is no architect mentioned, nor any one to whom all matters are referred, as they are in our days. The correspondence is carried on between the clerk of the works and the building owner, from whom instructions issue direct. Sometimes, however, a surveyor is employed to superintend, as was the case at Holdenby, for on one occasion when Lord Burghley was going thither and Sir Christopher Hatton was unable to receive him in person, the latter wrote a letter of welcome to his "singular good Lord, the Lord High Treasurer of England, at Holdenby," in which he begged his guest to give "his opinion to the surveyor of such lacks and faults as should appear to him in this rude building," which he averred was built "in direct observation" of Lord Burghley's house at Theobalds, and which he hoped might become really like it by means of Lord Burghley's corrections. How would an eminent architect in the present day like to have a high and mighty friend of his client's come down for the purpose of dictating alterations and corrections in a design practically completed? Perhaps, however, the request was merely a compliment on the part of Sir Christopher; at any rate Lord Burghley was charmed with Holdenby, praised its façade, ascent from the hall to the great chamber, and the largeness and lightness of the rooms. As for its being an imitation of Theobalds, truly the latter place he liked as his own, but it was only a foil to Holdenby. There was a certain amount of truth in this, for Holdenby was considerably larger, and was an improvement in many respects upon the older building. But they were both fine palaces. Holdenby, indeed, was a vast and stately edifice, suitable to an age which delighted in magnificent displays; and Sir Thomas Heneage declared it would hold the pre-eminence of all the modern houses he had known or heard of in England.

Most of the large houses of the time were thus superintended by a surveyor—or architect, as we should now call him—of whom the best known is John Thorpe. But his functions were far different from those that we have to fulfil. The hundreds of drawings that now go to the erection of any considerable building were wholly unknown. Plans and elevations were supplied, but, so far as can be gathered, the details were left to be arranged on the spot. A very much simpler method than ours, but one not compatible with the system of contracting, which demands that everything must be foreseen and tabulated, from a staircase to a chamfer stop, and that every variation from the pencil-and-paper arrangement shall be duly noted and valued. Gentlemen, the existence of the quantity surveyor is a marvellous tribute to the ingenuity of the human mind, and he is also one of the most noticeable barriers that divide the times of Elizabeth from those of Victoria.

But, gentlemen, it is not for us to deplore the fact that times have changed. They always have and they always will. It is for us to recognise that they have changed, and that we are expected to solve our own problems in our own way, instead of vainly seeking problems that may be solved by the old methods. The difficulties of Elizabeth's days are not exactly those of ours. The way in which the men of Elizabeth's days overcame their difficulties cannot be exactly our way. But we can recognise how well those difficulties were met, and if we are content to study the two things together, the questions and the answers, and to refrain from playing at cross-questions and crooked answers, we shall find great help in answering our own questions in our turn.

We have dwelt somewhat on the shortcomings of the architecture of Elizabeth's days to-night, but it must not, therefore, be supposed that we are blind to its excellences. The plans may be crude, but they are simple and stately in disposition, and the wants they had to meet were also crude. The elevations are to us always effective, partly from association but partly also from the quality of the means used. The mullioned windows give scale to the mass, the bay windows afford a simple method of avoiding monotony, the long lines of string-courses and the pierced parapets impart breadth to the design, while the gables and the tall chimneys produce a picturesque sky-line in a natural and easy manner. There is, undoubtedly, much in the detail of the time that is ill-considered and coarse, but we live in the light of the Victorian age, with all knowledge accessible and with better means for correcting our judgments and improving our tastes than were ever yet offered to mankind; and we may, if we will, find much in the architecture of Elizabeth which, purged of its coarseness and refined in the crucible of our minds, may go far to ennoble the architecture of Victoria.

The PRESIDENT, in inviting a discussion, alluded to Mr. Gotch as being engaged on a work illustrative of Renaissance work in England. He hoped its scope would be similar to that of the splendid work produced on the German Renaissance. Points in Mr. Gotch's address had recalled to his mind Bacon's description of the perfect palace. The study of it would be a good exercise for the imagination in the development of ideas of dignity, &c., which restricted sites did not afford. The treatment and unconventional use made of foreign forms gave these Renaissance buildings half their interest, and was one of the features which would repay study. Also the beautiful work in mantelpieces showed that the architects were masters of their art. Nothing, however, he thought could be more ghastly than some of the Elizabethan revivals, early in the century, carried out in Portland cement. What they had to consider was how to study the Elizabethan style with profit, and to select the best examples of the style for the purpose.

Mr. F. G. HOOPER proposed a vote of thanks to Mr. Gotch. The subject, he said, seemed a most appropriate one to bring before a body of students, as it dealt with a period when new demands were made on English architects and the opportunity was given of seeing how these demands were met. The time of Elizabeth was one of peace, and the system of fortified residences could be abandoned. The Church was being despoiled of its wealth to the enrichment of the nobles, who were anxious to show what could be done with the money, and the architects employed went abroad for their inspiration in Palatial style, the styles previously prevalent in this country being no longer suited to their wants. It would not fall to the lot of many to build a palace, but, in carrying out their more modest commissions, they could aim at some of the dignity for which the Elizabethan architects sacrificed everything. They need not sacrifice the comfort of the inmates of their buildings, but the designers could sacrifice their time in learning from the Elizabethan architects of England and of France. French architects held English architecture in great estimation, but they complained that it was too often wanting in dignity and simplicity.

Mr. H. O. CRESSWELL, in seconding the vote, said that perhaps the greatest blemish of Elizabethan architecture was slavish adherence to symmetry. As students they were taught the contrary to that, and to have a reason for each feature. As to the study of Elizabethan style one difficulty occurred, because it was a Renaissance carried out by men who believed they were reproducing Classic work, whereas an examination of the cornices, capitals, and other ornamental features, showed how great a difference there was between Elizabethan and Classic detail.

Mr. KERSHAW, M.A., said the special feature of interest that commended itself to their attention in the Elizabethan period was the originality displayed by the architects, who made their work a labour of love. He also expressed great admiration for the German Renaissance work.

Mr. L. A. SHUFFREY said that most of the charm of Kirby was the absence of that excessive symmetry found in the other Elizabethan buildings. They should be studied with caution, or they might get into difficulties. It must be remembered also that the buildings had gained much in picturesqueness by the softening hand of time, and being overgrown with moss. The effect of the architecture rising direct from the ground or the lawn seemed to him unsatisfactory. He also referred to the difference in building where time had not to be taken into account, and the system of the present day, when the whole building must be put on paper, and specifications drawn up for the quantity surveyor before a stone was laid.

Mr. BRODIE asked whether an architect in his design for a 20-foot street frontage should not pay some respect to the design of the next-door neighbour's house, by consulting to some extent the spirit of that design, instead of aiming at something quite different. The designs should not clash one with another.

The PRESIDENT put the vote, and it was carried by acclamation.

Mr. GOTCH, in replying, observed that he might say in confidence that he was engaged on a work on the English Renaissance on the lines of the German work mentioned by the President, and he hoped that in the forthcoming year some of the parts would appear. The President, he continued, had drawn attention to the terrible revivals in Elizabethan work. Those were failures because their authors had not gone the right way to work. If architects attacked their problems with common sense, they could go to Elizabethan times for hints, and by doing so obtain good results. But they must attack their problems in their own way, and while no styles of the past should be made their aim, they should be studied to learn how the architects of those days solved their problems. Mr. Aitchison had on a previous occasion suggested that the Association should give prizes not for any particular buildings, but for designs which embodied special ideas in architecture, that of dignity for one, as suggested by the President. Slavish

symmetry he condemned, but there was a line to be drawn between that and the extreme Gothic idea that every feature must have a distinct mission. If every window had to be varied according to the size of the room, the design would lose all rhythm. The English architects had not reproduced Classic styles. They had reproduced their recollections of Italian work, in other words, made reproductions of the imitations they had seen abroad. The effect of Burghley House was extremely marred by its rising from the ground without terraces, but originally he believed that the terraces existed. The builders of those days were more favoured, for they had not to build at railway speed as was now the case. The idea of assimilating designs of neighbouring houses, he thought, would not accord with the wishes of the owners, who desired to have no connection between their next-door neighbours or the man over the way.

The proceedings then terminated.

### MANCHESTER SHIP CANAL.

IT is just twelve months, says the *Manchester Guardian*, since the first sod of the canal was cut. On November 11 last year a number of the directors went over to Eastham and inaugurated the great work. Nothing could have been more simple than the ceremony. There was not a flag, not a note of music, not two words of a speech, not even a cheer. A spade which had seen some service, and had neither an ebony handle nor a silver blade, was handed to Lord Egerton by Mr. Walker, the contractor, and with this honest implement the chairman of the company, without more ado, delivered the first sod from its mother earth. The spade passed in turn to the directors, and each cut a sod. Mr. Leader Williams, the engineer, tipped a barrow containing the product of these labours, and the ceremony was at an end. The minute recording the proceedings states that the directors afterwards discussed "ordinary business." The necessary rudeness and bareness of all this is relieved by a single touch of sentiment. The spade with which the first sods were cut finished its work that morning, and now hangs, we believe, in Tatton Hall. Mr. Walker lost no time in buckling to his work. For some time he had been getting materials together, and within a week of the inauguration ceremony he had two thousand men on the ground. As the operations opened out, the forces were gradually increased, and at present the number of men is over 10,000. The men, however, represent but a small portion of the force brought to bear in this great digging enterprise. The bulk of the excavation is being done by the steam-digger, and of these mighty workers eighty-five have been pressed into service. Three of them are of German make, two come from France, and the rest are of English construction. In addition to these, 100 locomotives and 5,000 waggons are constantly at work, and the lines of rails put down for temporary purposes cover about 200 miles. So much effective strength has never before been brought to bear upon a contract of this kind, and as a matter of course the amount of work done has been enormous. The whole course of the canal is now in outline, and in some places the excavation is in a rough way complete. The progress made during the year is, we believe, regarded as eminently satisfactory, and there is every reason to believe the work will be finished to time. Mr. Walker has a name for getting done within the limit of his contract, and in the present undertaking his reputation is involved as it never was before.

It was on the site of the entrance locks that the directors cut the first sods. The particular spot has long since disappeared, and the whole look of the place has changed. The excavation in the great lock has been carried down to the invert level, a depth of about 50 feet. Further excavation will be necessary for foundation purposes, but the work is so far forward that the construction of the lock gates is in progress. It is difficult to give readers an idea of the great red gulf the steam digger has made here. The width of it is about 400 feet, and the average depth 35 or 40 feet. Its width of 400 feet it keeps for a distance of about 600 feet—the length of the largest of the three locks—and then tapers off into the ordinary width of the canal. In constructing locks of different sizes the engineer is, of course, not open to the charge made against the man who drove a large hole in his kitchen door for the cat and a smaller one for the kittens. Vessels of small tonnage could of course enter by the great lock, but it would be at an unnecessary expense of water. The great red gulf we speak of is a scene of enormous activity, and in face of the blinding smoke of locomotives and steam diggers it is not easy to grasp the details. At the lowest level the new red sandstone has been reached, and the final excavation will have to be done by blasting. But as a great deal of stone will be needed here for building purposes, it is no doubt convenient to have it at hand. Most of the marl and stone now coming out of this vast quarry goes towards Pool Hall, where the canal has to be taken across

a deep bight in the coast line. Some progress has been made with this work, but the embankment is not yet above high-water level. The number of men on the Eastham section is about 1,000, and for their accommodation a village of wooden houses has sprung up under the shelter of the hill. A new chapel, on much more handsome lines than the first hasty erection, has been built, and under the auspices of Mr. Morris, one of the contractor's agents, a reading-room has now been provided.

Between Ellesmere Port and Holpool Gutter the excavation has in various places been taken out to the full depth of the canal. Between Holpool Gutter and Weston Point the German steam digger has done good work, and is to have the assistance presently of one on the French system. The sluices at the river Weaver are to be started soon, and at the lock at Weston Marsh the work is so far forward that the concreting of the walls is now going on. On the Runcorn section progress is most noticeable at No Man's Land. Between Randle's Sluices and Latchford a great deal of blasting has been done, the rock coming nearer the surface here than at some other points. The diversion of the Mersey at Latchford Locks has been finished, and a start has been made with the railway deviation, which begins at a point near Warrington and ends at Thelwall station. Section No. 7 was the last section to begin work, but in the four months much has been done, especially in the excavation of the Irlam locks and the work connected with the deviation of the Cheshire Lines Railway.

The docks at Salford are in a forward state. As readers know, they are to consist of three branches opening out of the canal, which at this point is much wider than usual. The excavation of the mid branch is nearly complete, and on the Trafford Road side the concreting of the wall is in progress. The other branches are not so far advanced. The river will give some trouble at this point, and extensive works are in progress to take it out of the way for a time. The material dug out at Salford is mainly gravel, with clay and rock at the bottom. The gravel and rock will be used in making the concrete walls. The rest of the spoil is in part deposited on land near the racecourse, and in part sent down towards Stickins Island, where the diversion of the river is now complete. To a wonderful extent the various sections have so far turned out, as one might say, self-contained, each able to use up and dispose of its own spoil; and in a work extending over so many miles this is, of course, a matter of no small consequence.

### THE LIGHTING OF THE BURG THEATRE, VIENNA.

THE lighting of the new Burg Theatre in Vienna is on a scale that corresponds with the remaining work in a building which has taken fourteen years to erect, and has cost about a million sterling. The installation of the electric lighting was entrusted to two engineers from Geneva—MM. Emile Secheyay and Auguste Gardy. The plans were by M. Turrettini, and the general contract for the lighting was taken by the Imperial Continental Gas Association. The central station contains eight steam-engines, which act upon the dynamos, and through them transmit the currents underground by cables to the three batteries of coupled accumulators in the basement of the theatre. Owing to the strength of the batteries, from four to five thousand lamps can be kept alight during a performance without the aid of the engines. Two batteries are reserved for the illumination of the theatre in general, while the third is assigned for the stage exclusively. The connections are so arranged that each circuit can be put on either of the batteries, and in that way an equal and regular discharge is insured. The wires and cables have a length of nearly seventy miles. There are 5,300 lamps, varying from 10 to 40 candle-power each; the salle has 720, of which 370 are in the central lustre; the foyers, corridors, and staircases have 1,800; the rooms for performers, the ateliers, &c., have 800, and the stage alone has 1,970 lamps, being equivalent to 50,000 candle-power. An apparatus is employed to produce effects of dawn, night, lightning, and other combinations on the stage. The appliances have been specially designed, and are excellent examples of bronzework. An experience of fifteen months in the Vienna Opera House with 7,000 lamps has demonstrated that by the aid of accumulators illumination can be obtained which is equable and agreeable to the eyes, and that extinction becomes an impossibility.

A New Public Hall has been erected at Victoria Park, the ventilation of which has been carried out on the Boyle system, the latest improved form of the patent self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

## NOTES AND COMMENTS.

It will be strange if we allow the Americans to anticipate us in the creation of a committee of taste, with powers to prevent the creation of eyesores in public places. The district of Columbia was able to pioneer a Bill through the Senate with that object—and similar Bills would be sure to follow from the remaining parts of the United States—but the excitement of presidential and other elections impeded its progress to the final stage. The project is, however, suggestive. The Art Commission was to consist of four eminent sculptors, four eminent painters, three eminent architects, and three to be selected "from other employments for their knowledge and good taste in art," all being nominated by the President. Four of the first batch were to hold office for one year, five for two years, and five for three years. Their successors were to be in office for three years. The architect of the Capitol was to be secretary and an *ex officio* member of the Commission. All the members were expected to serve without receiving more than their travelling expenses, which were to be audited by the secretary. The meetings were to be held at least once a year. The duty of the Commission was to "report upon the character and value of such plans of public buildings, monuments, or works of art as shall be referred to them by either House of Congress or the Joint Committee on the Library, and, when authorised by Congress, to select from designs offered by competitors for works of art ordered by Congress, and to render such other service as may from time to time be required of them by Congress." It is a pity so desirable a measure has not become law, but there may still be a chance for it.

It is proposed to fill the great west window of Gloucester Cathedral with stained-glass, as a memorial of the late Mr. GAMBIER PARRY. There could hardly be a better form of memorial, for Mr. GAMBIER PARRY was at one time almost as strong an enthusiast as Mr. WINSTON about stained-glass. Gloucester should respond generously to the appeal for the necessary funds, for Mr. PARRY rendered many services to the city and county. Besides, his distinction in the arts was reflected on that part of England. Mr. PARRY could talk and write well about art, but he could also paint better than most amateurs. His discovery of an enduring medium for use in wall-painting also merits recognition. The memorial-window should be entrusted to capable hands. We make this suggestion as it is proposed to make over the surplus funds to a child's hospital in which Mr. PARRY took much interest, and there is a temptation to stint the expenses on the window in order to enrich the hospital.

On Thursday in last week M. DE BAUDOT, the Inspector-General of Diocesan Works, began his course of lectures in the Galleries of Comparative Sculpture in the Trocadéro, Paris. The lectures will treat of French architecture from the thirteenth to the sixteenth century, and will explain the æsthetics of the style, the systems of construction and of ornamentation. The relation of the architecture of that period to the Renaissance will be discussed, and finally the advantages of a study of French architecture of the Mediæval and Renaissance periods will be impressed upon the auditory.

VASARI does not mention either the time when the elder PALMA was born or in what place. The painter is simply called a Venetian. Later researches established that his birthplace was in Serinalta, near Bergamo. Some critics have argued for PALMA's Venetian origin on account of the similarity between his works and those by GIORGIONE and TITIAN—indeed, in galleries his pictures often bear the names of those artists. A Bergamese influence is also discovered in his works by critics of a different class. An inquiry into the history of PALMA was lately undertaken by Signor FORNONI, of Milan. He has ascertained that the painter was a native of Serinalta, but the most remarkable discovery is that the true name of the artist was not PALMA but NIGRETTI. Whether writers on Italian art and the curators of galleries will take advantage of the discovery remains to be seen, but for the present generation at least the painter must be known as PALMA VECCHIO.

THE conversazione of the Birmingham Architectural Association, which was held in the Edgbaston Assembly Rooms, attracted about 300 members and friends. The proceedings commenced with a reception of the guests by the President and committee, after which a few selections of instrumental music were given in the ball-room. In the drawing-rooms were arranged a large collection of sketches and photographs, with some specimens of local art manufactures. The dancing began at 9.0 P.M., and was carried on for several hours. The conversazione was enjoyed by all who were present.

At the meeting of the Leeds and Yorkshire Architectural Society on Monday, the prizes were distributed after the delivery of the President's address. Mr. J. E. PRESTON obtained the President's prize of five guineas, with an extra two guineas for measured drawings of Harewood Church. The prize for members of the Associates' Sketching Club was awarded to Mr. CARBY HALL, with one for an essay. Mr. A. E. KIRK gained the prize for design.

At the present time there are 280 musées (picture-galleries and museums) in the provinces of France, to which the State contributes 300,000 francs a year. But that sum is supplemented by valuable gifts from private persons. The musées are divided into four classes. In the first class are such musées as the one in Lille, which is worthy of a metropolis. One great advantage of the provincial galleries is that they afford opportunities for the purchase of works by local artists who have made a name in Paris. The conservators of the local museums will be able to render valuable aid to the exhibition of retrospective art which is to be held next year in connection with the International Exhibition.

THE Irish mathematicians were at one time among the most zealous adherents of science in its "pure" form. But of late they have followed the example of mathematicians elsewhere, and have become adherents of the graphic method of solving difficulties. On Monday last Professor HAUGHTON, speaking as president of the Royal Irish Academy, said:—"The whole tendency of modern science is to substitute graphic methods for elaborate calculations. The figures are drawn by geometry, simple figures as conic sections *à fortiori*, simple figures as circles. When you want extreme accuracy you make your drawing on a larger scale, and by rapid drawing of a very wide kind you get approximate to the exact result. This is an enormous advantage, because you take the first results of the graphic method, and you see where the critical points of the calculation are, and, instead of going through the frightful labour of an arithmetical calculation of the whole, your attention is concentrated on the critical points of this graphic method. In application to physics the graphic method does not dispense with calculation, but diminishes the labour and concentrates the attention into the most minute details of the calculation." The President was probably thinking of results of a more or less general kind, but his words are almost as applicable as a description of the saving of time and the certainty of conclusions which are derived by the graphic method in constructive problems.

THE advantage of a clerk of works is not generally recognised in America. The following resolution on the subject was passed at the last Convention of Architects:—"The American Institute of Architects recommends as proper and desirable, the employment of a clerk of works in the erection of all buildings of importance as a means of obtaining the best results. He should be paid by the owner, but should be appointed by and under the direct control of the architect. The architect's supervision of and responsibility for the work should be in all cases insisted upon as vital to the vast interests of the owner, but such constant oversight as can be exercised by a competent clerk of works is an invaluable adjunct to the labours of the architect in securing uniformly good and honest work." The resolution is plain, and contains no statement which is not borne out by practice.

### THE HUT, PINNER.

THE Hut, Pinner, now in course of erection for Lady WATKIN WILLIAMS, and of which we give illustrations in this number, is from the designs of Mr. JAMES RANSOME, architect, 26 The Boltons, S.W. It has been the architect's object, while keeping a practically square plan, with a view to minimising the cost, to obtain at the same time a picturesque exterior, and this he has achieved in spite of the total absence of unnecessary ornamentation about the structure by treating it in a simple English manner. The ground floor is in red brick, the first floor in half-timber construction, the posts being tarred, with distempered rough cast between, while the roof and gable over porch are hung with red tiles. The building contains three reception-rooms, all approached from the hall, and opening on to the loggia; seven bedrooms, a small boudoir, and the usual offices, bath-room, &c. Mr. BATCHELOR, of High Street, Harrow, is the contractor.

### LEEDS FINE ART GALLERY.

THE Leeds Fine Art Gallery forms an annexe to the large block of municipal offices which adjoins the Town-hall in Victoria Square. The art gallery portion of the building, erected at a total cost of from 10,000*l.* to 11,000*l.*, from the designs of Mr. WILLIAM H. THORP, A.R.I.B.A., was opened on October 3 last by the Mayor, Alderman A. W. SCARR, in the presence of the Marquis of RIPON, the Bishop of RIPON, Sir CUNLIFFE OWEN, the Lord Mayor of YORK, and the mayors of fifteen Yorkshire towns, Professor HERKOMER, A.R.A., and others. The following description appeared in one of the local papers and is fairly accurate:—

Mr. Thorp's building is in the Italian-Renaissance style of architecture, designed to agree with the adjoining municipal offices. The elevation to Centenary Street is faced with the best Bolton Wood stone; also the return ends to Alexander Street; the rest of the elevation to Alexander Street is faced with the best hand-pressed bricks neatly pointed. The architect has been guided largely in the leading features of the arrangements of his design by those of the Walker Art Gallery, in Liverpool, which is justly considered in these respects one of the finest provincial galleries in the kingdom. From the vestibule adjoining the sculpture-gallery, the new reading-room 100 feet by 32 feet is directly entered, while to the left the vestibule leads to three picture-galleries, two of 20 feet by 21 feet, and one now called "The Queen's Room," in size 42 feet by 36 feet. The centre of the site is occupied by the lofty, glass-covered central court, from which, as well as from Centenary Street, the reading-room obtains light. A conspicuous object in the centre is a fountain of glazed Burmantofts faience. This court is 60 feet by 36 feet, and is used for museum purposes, another museum court at the side being 60 feet by 25 feet, and another fronting to Alexander Street is 65 feet by 26 feet. The picture-galleries and central court are all throughout lighted from the roof. From the vestibule a fine staircase of ample dimensions ascends to the upper floor, where the space around the central court is utilised for picture-galleries, two fronting to Centenary Street measuring respectively 41 feet 6 inches by 30 feet, and 87 feet by 32 feet; the one on the opposite side of the court area being 60 feet by 24 feet, and the one across the Alexander Street end 64 feet by 25 feet. A small balcony completes the quadrangle; and there is also over the vestibule a gallery 41 feet 6 inches by 36 feet. The central court of the museum is approached from the staircase hall by means of an archway 13 feet in height underneath the centre of the staircase. An additional entrance to the reading-room is provided at the corner of Centenary Street and Alexander Street. The new reading-room coincides exactly in area with the old one. A new large picture hoist is provided with communications on each floor, and a large packing-room in the basement, with access to the open yard. The galleries are divided one from another by fireproof doors sliding into recesses in the walls. The walls of the galleries are lined with match-

boarding for convenience of picture-hanging, and the ceilings under the lanterns coved in plasterwork. The floors in all cases are fireproof, of iron joists and concrete. The roof over the central court is arched with wrought-iron ribs and glazed with Rendle's patent glazing. The columns in the vestibule and staircase wall and the staircase balustrades are carried out in polished Hopton Wood limestone. In "The Queen's Room" is a fine frieze, designed by Mr. Thorp, and carried out by Mr. J. W. Appleyard, which is relieved by panels bearing the names of Hogarth, Reynolds, Gainsborough, and Turner. The building is heated with hot-water pipes and well ventilated. It is lighted by electricity.

The work has been well carried out by the contractors, MESSRS. CRAVEN & UMPLEBY, of Hartley Hill, Leeds, Mr. J. T. BROWN being clerk of works.

### THE CHURCH OF ST. MARY-LE-STRAND.

THE rector and churchwardens have issued an appeal for funds to restore the church of St. Mary-le-Strand to its original state. To effect this it will be absolutely necessary to remove all the fractured stones and to cut out from the wall the iron chain bonds and cramps which have oxidised and split the stones, and which, unless removed, will continue to injure the building. The cost of thoroughly restoring the church and making it safe for public worship has been estimated by an architect of experience at about 3,000*l.* The parishioners are quite unable to defray the cost. The population of the parish is nearly 2,000, and those living behind the Strand are for the most part very poor people. The church in the Strand is the only place of worship which they can attend. It is, therefore, urgently necessary to solicit those who have the means to come forward as speedily as possible to save this beautiful building. The Bishop of London recently wrote as follows:—

"It is one of the most beautiful churches of its style that we possess, and the very greatest ornament to the spot where it stands. As it needs repair, I think you would not find an appeal to the public in vain. I beg of you to do your part to prevent so beautiful a structure from being defaced or destroyed. It will be a discredit to us in the eyes of all Europe if we show ourselves careless of such a work of art, long ago dedicated to God, and still serving the great purpose of uniting religious feeling with love of what is beautiful."

### THE LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.

ON Monday evening the thirteenth session of this Society commenced, when Mr. Henry Perkin delivered the following address:—

As President it devolves upon me to open the session with an address from this chair, and having been a member of the Society since its formation in 1876, I have had an opportunity of watching and assisting its progress.

I can with pleasure congratulate you upon the sound condition of the Society, which I may do with reason, considering the conflicting interests which necessarily arise in a profession on such an unsettled basis as ours. Bearing this in mind, let me press upon you all the desirability of keeping up the spirit of good-will and mutual respect which distinguished our Society at its outset, and let me invite you (as I do with all cordiality) to assist me in endeavouring to maintain the dignity of the chair, and to promote the welfare of the Society during my term of office as your president.

The subjects which are appropriate for mention in an address of this kind are too numerous to treat fully. I have therefore made a selection of some items upon which I will say a few words.

The chief subject that has engaged the attention of our profession during the last year or more has been the question of "The proposed federation of Provincial Architectural Societies of British Architects," and I would point out to you that a copy of the "draft by-laws under supplemental charter," together with an invitation to become affiliated, has been received for our consideration. The proposed by-laws are arranged on a wider basis than those now in use, as in the following instances:—1. A seat on the Council of the Institute for the president of an affiliated Society (provided he is a member of the R.I.B.A.). 2. The substitution of voting by proxy for the expensive system which necessitates the attendance of country members in London. 3. A reduction in members' subscriptions of Societies affiliated to the Institute, and other minor matters which I need not enumerate.

There is one other point in connection with the business of the Institute which is perhaps of more importance than even

the federation question, I refer to the desirability of a diploma to practise architecture. This burning question has been shelved, although on this matter a predecessor in this chair, in 1885, said, "The Council of the Institute is in one respect entitled to unstinted praise. They have at last boldly determined to grapple with the diploma question in such a manner as to settle it permanently and effectually." From what I can gather (and in this I am corroborated by Mr. Waterhouse in his presidential address at the Institute last Monday), the Council of the Institute now considers that membership of its ancient body is a sufficient guarantee to the public of an architect's efficiency. With this conclusion we do not agree, and therefore cannot consistently be seen lodged in the same camp. Hence the logical necessity for our Society, and others who agree with us, to hold aloof from the Institute until it shall declare itself able to see eye to eye with us. Compulsory examination for membership of the R.I.B.A. will not meet the case, as hundreds of practitioners will remain outside and continue to practise as now, and the public will not have the advantage of a guarantee where most needed. Lapse of time has shown that the R.I.B.A., with its limited influence, is powerless to do much to protect our profession from empirics.

With a diploma to practise, I see the possibility of meeting the two chief disabilities from which we now suffer. In the first place, the average character of our architectural works is considerably below what it should be; because the public, being for the most part ignorant of architectural art and the proper procedure in regard to building matters, has been unable to discern who would be its best advisers; whereas, with the diploma it would have a guarantee that it had retained at least a man with practical and scientific knowledge, if not possessed of artistic ability, and this latter quality is not always required in every class of building. In the second place, with a diploma we should be able to regulate our numbers with more certainty than at present, and so prevent that overcrowding which brings about such lamentable results, and which acts with more keenness because, in the practice of architecture, the amount of work increases and decreases with greater uncertainty than in any other profession; besides, the necessity for passing examinations would draw into our body a better educated class of youths than those who now, in a haphazard sort of manner, scramble into it under the present ill-regulated system. I call to mind the case of a youth who not having completed his articles, commenced practice in a rapidly increasing neighbourhood, and secured considerable patronage. I need hardly point out to you that, under such circumstances, the property he erected is worth considerably less than would have been the case had a competent architect been employed.

If action could be taken by provincial societies to bring pressure to bear upon the Institute towards the attainment of the diploma, I am sure we should willingly lend our aid; therefore let us, in the meantime, maintain an independent position, until our united effort should induce the Institute to make an effort to band together the irregular troop of practitioners who now, according to their very diverse abilities, regulate building for an innocent public.

Up to the present, provincial societies have supported the prestige of the R.I.B.A., being of opinion that it would be better able to secure a diploma for the profession if only it could be induced to cast aside its old traditions and keep up with the spirit of the times. It is grievous to find that, after all the years of agitation in favour of the diploma, we should have to do the work again. I trust we shall not let the question rest, but renew our efforts with all energy, and I have no doubt they will eventually be crowned with success, and the practice of architecture take its legitimate position as one of the learned bodies.

There is another matter which has been referred to more than once by previous presidents of our Society: I mean the methods of conducting architectural competitions. As far as we architects are concerned, the great evil from which we have always suffered is the fact that we have no voice in the terms on which the transactions are conducted. We are individually compelled to compete and accept conditions offered us because we have no organisation strong enough to protect our interests. If the promoters of large competitions would advertise in the first instance for architects willing to compete, and then confer with them on the terms of the transaction, a great step in advance would be taken. It is certain if we do not arrange for fair terms on a legal basis before the competition takes place, we are not likely to obtain them afterwards. There should be a distinct contract between the promoters on the one hand, and the competitors on the other. It seems extraordinary that architects are so little able to protect themselves in a matter where so much expense is involved, experience having shown that we annually throw away thousands of pounds on ill-regulated competitions.

The problem before us is to reduce the waste of expenditure on competitions, and this may be accomplished in more ways than one without detriment to the public. It may be done by

limiting the competition to a selection of architects who are known to be more or less qualified for the work. Where it is found imperative to have open competitions (as in public and national buildings), care should be taken that the style of drawing and class of draughtsmanship be definitely fixed, otherwise the expenditure involved in elaborate water-colour drawings, mounts, and gold frames has no limit. Many a competition has been won solely by unstinted expenditure in this direction.

In the case of limited competitions, the money usually offered as premiums should be equally divided amongst the unsuccessful competitors, and the execution of the work entrusted to the author of the selected design. In public, open competitions, the premiums should be of equal value and more numerous than the first, second, and third prizes generally offered, and the first of which is one in name only, as it merges into the commission in case the work is placed in the hands of its author; thus the promoters get all the designs for the amount of the second and third premiums, the first being put forward as a bait, and the bulk of the expense falls upon the competitors, many of whom from inexperience are only too willing to compete upon any terms. It is not to an architect's advantage to work for the amount of the prize money, but it is for the execution and profit of carrying out the buildings that he competes.

If architects would take up this question and refuse to compete except under conditions to be agreed on, a large amount of unnecessary labour and cost would be saved to competitors, and men of high ability, who now refrain from entering the lists, would be induced to do so, and the public would have greater respect for us, if able to protect our own interests.

I do not propose following the custom of giving a list of buildings erected in this district during the past year, but I wish to mention the new Municipal Art Gallery. I am sure you will all agree that our friend Mr. Thorpe, in spite of the limited sum at his disposal, has produced a building admirable in every respect; and Colonel Harding, and other promoters, have earned the thanks of lovers of art, for providing a means of elevating the taste of the public on a question in which we, as artists, are so deeply interested.

I may also state that improvements are being effected in Briggate, where another arcade is in course of erection, and I hear a third will shortly make its appearance on the east side of the same thoroughfare. It is satisfactory to find that a large quantity of tumble-down property will be effaced from the heart of the town by these undertakings.

The chief extension of trade in this borough has lately been in the manufacture of wholesale clothing, in fact, the headquarters of this most enterprising branch of our commerce are now firmly established here, and large factories (in addition to those already erected) are being built to meet the growing demands of the trade. I note also the great increase of dwellings for the artisan class, which are springing up like mushrooms on every side of the borough.

We shall regret that the negotiations for the purchase of the Coloured Cloth Hall, and the buildings on the Quebec Estate by our Corporation, have, up to now, proved an utter failure, resulting from the exceeding care with which the authorities employ the borough funds. So much has been said upon this question, that I merely make a passing allusion to it, and put upon record our views, that the Council should not delay the purchase, with its consequent advantages to the town, for the sake of the amount in dispute, and so lose the opportunity for carrying out a long-wanted improvement. There can only be one opinion, that the approaches to the railway stations are quite inadequate, and an alteration permitting the erection of a new post-office would be a boon.

And now let me just for a moment refer you to the fine old abbey which stands almost at our door, and is in danger of destruction, or even worse. You will, I am sure, not think it out of place that as your representative I should urge upon the municipal authorities the desirability of acquiring and protecting from future damage this national monument, a valuable example of our ancient architecture. About fifteen years ago, you will remember, an attempt was made by a committee of gentlemen to purchase the abbey, with a view of restoring it to use as a church and clergy college. The late Sir Gilbert Scott reported favourably upon the feasibility of the scheme. It seems to my mind undesirable to utilise the building for modern purposes, which would necessarily involve alterations lowering the value of it as an historical record. At any rate, let us hope that negotiations for acquiring the abbey and grounds may meet with success, and that they may be preserved with care and veneration for the pleasure and education of ourselves and those who come after.

And now a few words upon the subject of County Boards, the formation of which will shortly take place, and no doubt will be of some interest to us as architects. In many cases existing buildings will (with partial alterations) be made available for the requirements of the Councils; but probably some new buildings will be required, and it will be interesting to observe

if the works will be placed in the hands of qualified architects. Much will depend upon the social standing of those elected to the County Boards. Up to the present, it is gratifying to find that the candidates who have signified their willingness to stand for election are of a high class, and we may augur from this that our profession will receive more encouragement than it usually does from municipal authorities.

An occasion of this kind gives us an opportunity of coming in touch with the public, and of showing the advantage of our services to them upon those points which at present they seem unable to appreciate, and which the following examples will illustrate. A city corporation being about to enlarge its ancient guildhall, has instructed its surveyor to carry out the works, with the assistance of an architectural draughtsman whose salary is not to exceed three pounds per week. No doubt this is a very economical arrangement so far as professional payment is concerned; but on the other side, what is to be said of the treatment the ancient edifice will receive, or of the probable extravagant cost that may accrue from the fact of the work being placed in incompetent hands?

Take another case. A large pile of buildings has recently been erected under the direction of a county surveyor, who for his extra services was paid about one-third the commission usually paid to architects. The authorities by this arrangement have saved a considerable sum in architect's fees; but if the works had been placed in the hands of an experienced architect, it is highly probable that the amount saved in the outlay upon the buildings would have been very much more than the commission, as the structure would no doubt have been constructed in a less extravagant (but equally substantial) manner by an architect than by an engineer accustomed to works of a more ponderous nature, and the gain from an artistic point of view would have been considerable.

In spite of the words of warning and encouragement given by my predecessor from this chair to our students, it is lamentable to find there has again only been one aspirant for the silver medal of the Society. And the Associates' Sketching Club has not maintained the reputation which it earned since its formation. This, I believe, has partly arisen from the removal of its two most prominent members from the town, who took great interest in the management of the club. One of them has returned, and I have reason to hope that the club will be placed on its former footing. I am most anxious to draw the attention of the students to the classes at the Yorkshire College—those on "Building Construction" being held under the direction of Professor Barr—and also to classes for the "higher forms of draughtsmanship," organised by Mr. Stephenson, who has recently been appointed head of the art department. Surely it is not too much to expect that our young men will supplement their studies by these means; for, depend upon it, the time is not far distant when the only entry into the profession will be by examination for a diploma. Unfortunately, there are some who act in matters relating to architecture and its subservient arts as though everything has been accomplished, and that nothing remains for us but to mix together the productions of our ancestors, and then dignify them with the title of designs. Opposed to this retrograde state of art, experience has shown that a skilled artist may produce new combinations of form with as much ease as a musician can produce changes of sound; we cannot make progress in any branch of our art by a slavish adherence to mere precedent. Every one views with admiration the richly elaborated windows of "airy tracery," whose fragile forms would almost seem to contradict their antiquity, and the intricate network on the towers of continental churches. Why, I ask, should not we inherit the spirit which prompted their designs? There is no mystery about the matter, for all forms are founded upon simple geometric laws, quite as palpable now as of old. Shall we make use of those laws? Shall our designs stand on their own merits, side by side with those of our forefathers? Let us extend our knowledge by utilising their experience, and try as far as we can to grasp the spirit of their work; but whilst admiring their charms, let us avoid mere copyism, so fatal to the progress of true art, and thereby rendering the would-be artist essentially a mechanic. Painters would not permit themselves to reduce their art to this degraded state; neither do sculptors rise as mere adapters of earlier works. Why then should the architect be chained to slavish imitation of the works of his ancestors? Let us, therefore, strive to render our art in its very best forms and worthy of the acceptance of our patrons.

And now, before concluding, let me on your behalf offer a tribute to the memory of our talented brethren who have passed away, notably, Edward PAnson, president of the R.I.B.A.; Sir Horace Jones, architect to the City of London; George Godwin, Royal Gold Medallist; and A. J. Beresford Hope, past president of R.I.B.A., and who, as an amateur, devoted much of his leisure in furthering the cause of art. The provinces have lost Cornelius Sherlock, Liverpool; James Salmon, Glasgow; and very recently James Sellars, Glasgow, who died at the early age of forty-five—all (with the exception of Mr.

Beresford Hope), I believe, men who have by their talents as designers, or as upright practitioners, contributed to the honour of our calling.

Gentlemen, I have to thank you for the forbearance with which you have listened to my observations, and which have been of a dry nature; nevertheless, at the risk of tasking your patience for a single moment, I would add that our list of papers for this session will be of a most instructive and entertaining character, three of them being of a popular kind. One will be delivered by Miss Garrett, of London, the subject of which is "Interior Decoration and Furniture." I sincerely hope that you will all as often as you can attend the lectures, so that those who read the papers for our instruction and amusement (each of whom comes from a distance) may receive a hearty welcome and due acknowledgment for their kindness.

#### COVERED WINDOWS AS ANCIENT LIGHTS.

ON Saturday an important judgment was given by Mr. Justice Kay in the case of *Cooper v. Straker*, which determines the question of how far windows which are almost continuously closed by shutters can be considered as ancient lights. The plaintiffs are the owners of a warehouse 80 feet high, which is used as a wool store. Most of the windows have iron shutters which, as a rule, are kept closed, but are opened when required. In 1887 the defendants removed some cottages and stables which stood opposite the north-west front of the wool store, and began to erect premises of far greater height upon the ground. An action was brought by the plaintiffs for an injunction, and the trial lasted three days. Judgment was reserved until Saturday.

Mr. Justice Kay said:—This case raises the question which has often been discussed in actions concerning light and air, namely, what amount of user is requisite to entitle the owner of a building at the end of twenty years to the right of receiving the light which passes over his neighbour's land to the windows of that building. The building now in question is a wool warehouse situate near Bishopsgate Street, in the City of London. The whole of this warehouse, except the top storey, was built in 1864. The windows which are now in question are—one upon the ground floor and the windows upon the first and second floors immediately above it, and also two adjoining windows on the last two mentioned floors, all of which, so far as the window openings are concerned, have existed in their present condition since 1864. The warehouse has been used all that period for the storage and sale of wool. There are, in all, six storeys above the basement, including the ground floor. The topmost storey is lighted by numerous side windows and also by skylights. The storey next below is lighted to some extent by the same skylights, by means of trap-doors underneath them in the floor of the topmost storey. Four or five times in a year there are public sales of wool in this warehouse, which last for six weeks at one period of the year, and shorter periods at the other sales, the shortest being about a fortnight. The windows in question, and most of the other windows in the building, have shutters of sheet-iron, like folding doors, hinged to the outside of the window openings, which when closed would completely exclude the access of light to the windows, and these shutters on the three lower floors were kept shut except when the business of the warehouse required them to be opened. Each floor had loop-holed doors for taking in bales by the aid of cranes, and in these doors were glass windows, considerably smaller than the proper windows of the building, but they were not closed, as I understand, by shutters. Bales were usually stored on the ground, first and second floors of this building by piling them up in every available place, including the space in front of the window openings, inside the rooms; but they were continually being moved for the purpose of the sales, and when they had happened not to be in front of a window, the shutters of that window would be opened to admit light for any work that might be going on near it. I have positive evidence of persons employed in the building that this was the case as to all the five windows now in question, and I think the true result of that evidence is that the shutters of all these windows were occasionally opened for the purpose of admitting light to the several rooms; that this occurred very seldom to the window on the ground floor, more frequently on the first floor, and still more often on the second floor. With respect to all these five windows I think that the shutters were more generally closed than opened. The claim of the plaintiffs is rested on section 3 of 2 and 3 Will. IV., cap. 71, which enacts "that when the access and use of light to and for any dwelling-house, workshop, or other building shall have been actually enjoyed therewith for the full period of twenty years without interruption, the right thereto shall be deemed absolute and indefeasible." The section requires that two things shall have been enjoyed—"access," which I think means over the neighbour's land, and "use," which must be the use of light so coming by the person who claims the right conferred by

the statute. Both that access and use must have been actually enjoyed with the house, and for the full period of twenty years without interruption. It was decided in *Flight v. Thomas* (8 "Cl. and F." 231) that the interruption there meant is explained by section 4 to be an interruption by the owner of the neighbouring land acquiesced in for a year. No such interruption has occurred in this case. It is not suggested that the plaintiffs have abandoned their right, as in *Moore v. Rawson* (3 "B. and C." 332), where the owner of the house, it was held, had done so by pulling the house down and building on its site a stable having a blank wall, which existed about fourteen years without any window. But the argument is that the plaintiffs have not enjoyed the use of light to these windows, or, at any rate, to the ground-floor window, within the meaning of the statute. That depends upon the signification of the words "actually enjoyed." Enjoying the use cannot mean shall have continuously used. If that had been the intention of the statute some such word as "continuously" should be found in this section, and it might then be necessary to show that the plaintiffs had never closed their shutters for a day during twenty years next before the action. I take "enjoyed" to mean, "having had the amenity or advantage of using" the access of light. That is nearly equivalent to "having had the use," the intention being that the owner of a house may acquire the right to have the access of light over adjoining land to an opening which he has used in such manner as suited his convenience for the passage of light during twenty years. One of the cases which touch this question most nearly seems to be *Yates v. Jack* (1 "Ch. App." 295), in which Lord Cranworth decided that the right conferred by the statute is an absolute indefeasible right to the enjoyment of the light without reference to the purpose for which it has been used. This was concurred in by Lord Chelmsford in *Calcraft v. Thompson* (15 "W. R." 387). In *Courtauld v. Legh* ("L. R." 4, Ex. 126) it was decided that the right was acquired for a house which was completely built and had windows in it, though it was not internally finished, and had not been inhabited except for a portion of the twenty years before action brought. It was held that this was an enjoyment by the owner of the use of the light, one of the learned Judges saying that this view met the justice of the case, because the intention to use the windows was unmistakably indicated. Baron Cleasby says that the fallacy of the defendants' arguments was "in assuming that for actual enjoyment of light the party having it must take all the benefit which he could derive from its use." Baron Channell intimates that there might be an exception in the case of windows with iron shutters fixed behind them, but the essential word in that sentence is "fixed," which obviously means either shutters that will not open, or shutters that are never, in fact, opened during the twenty years. It was argued that such a use as was made of the windows in this case would not intimate to the owner of the adjoining land that light was being enjoyed. I do not agree with this argument. If it be essential that the light should be so enjoyed as to give him notice, the window openings in this case were formed in 1864. The shutters were movable; they were opened from time to time; and he must have been extraordinarily negligent or indifferent if he did not from these facts understand that a right might be gained. I asked counsel how often the shutters must be opened during the twenty years to gain the right conferred by the statute. The answer was, a reasonable number of times. That would be to determine an uncertain thing by something still more uncertain. The owner of the dominant tenement might well say, "My use has been reasonable; this is my mode of enjoying the light; you might have stopped it if you pleased at any time within twenty years." I am of opinion that, in the case of windows with movable shutters, which are opened at the owner's pleasure for admission of light, the right is gained at the end of twenty years if he opens them at any time he pleases for the admission of light during those twenty years, and there is no such interruption of access over the neighbouring land as is contemplated by section 4. In such a case, it being proved that the window openings have remained unchanged for twenty years, and that the shutters were constructed so that they might be opened or closed at the pleasure of the owner, in my opinion the onus is thrown upon the owner of the neighbouring land to prove that the right has not been gained. In this case he has not proved this. I think that, under the circumstances, the plaintiffs have acquired an absolute right to all the light coming to their ancient windows over the defendants' land, as it has come during the twenty years next before this action, just as though these windows had been open for the admission of light during all that time. By consent of both parties the matter was referred at the trial to two arbitrators and an umpire, who were to inquire whether the proposed building was proper; and if not, to determine what sort of building the defendants might erect. The umpire has made a report, the effect of which is that the building proposed to be erected by the defendants, according to the last plans submitted by them to the plaintiffs, would have interfered too much with the access of light to the windows in

question; and he has described the building which the defendants ought to erect. The defendants, before the trial, suggested an arbitration, which was not agreed to; and on that ground they now urge that costs should not be given against them. If they submitted to the finding of the arbitrators or umpire there would be some reason in this; but they do not submit to the award which has been made, and have raised questions of law which, if they had succeeded, would have defeated the findings of the umpire. I must now grant a perpetual injunction to restrain them from erecting any building upon their land which will interfere with the light coming to the plaintiffs' ancient windows more than the building recommended by the umpire. The defendants have been wrong throughout, and must pay the costs of the action and reference.

### THOMAS USTICK WALTER, THE AMERICAN ARCHITECT.\*

THOMAS USTICK WALTER, second president of the American Institute of Architects, was born in the city of Philadelphia, September 4, 1804, and died in the same city, October 30, 1887, being at the time of his decease the oldest practising architect in the United States. He was the son of Joseph S. Walter, and of Deborah, his wife, and was named after the Rev. Thomas Ustick, a well-known divine during the early years of the present century.

In boyhood Mr. Walter displayed a predilection for mathematics. His education was liberal, but not scholastic. In 1819, being then fifteen years of age, he entered the office of William Strickland, the architect of the Custom House, the Mint, the Merchants' Exchange and Marine Asylum, and other buildings in Philadelphia, and of the State Capital of Tennessee, in Nashville, within which structure he is buried under a suitable monument. From his own writings it is learned that Mr. Walter remained with Strickland until he had acquired the art of linear drawing and a general knowledge of the profession of architecture, after which he resumed his general studies, and went through an elaborate course of mathematics. During seven years he devoted himself to the study of physical sciences, to the cultivation of the arts of drawing and painting, and to the attainment of practical knowledge of the several branches of mechanical construction, while at the same time, in his moments of leisure, he studied landscape-painting in water-colours under the direction of Wm. Mason, a celebrated teacher of that art in Philadelphia.

In 1828 he again entered Mr. Strickland's office, devoting himself exclusively to architectural study, the practice of which he commenced in 1830, and in the following year designed the Philadelphia County Prison, which was his first important work, his plan for same having been adopted and the construction of the work entrusted to his care.

In the year 1829 he was elected a member of the Franklin Institute of Pennsylvania, and subsequently was elected one of its Board of Managers, and in 1846 was chairman of the Board. Mr. Walter's interest in the Franklin Institute was manifest from the first, and he entered heartily into its councils and discussions. At this early date the public taste for correct architecture was wholly undeveloped, but he worked and argued for the advancement of his art. This enthusiasm bore fruit; and in 1835 it was voted, "That a course of lectures on architecture delivered annually before this Society is indispensable, as well to accomplish the ends as to promote the prosperity of the Franklin Institute; and that it is hereby recommended to the Board of Managers to secure the delivery of such a course next winter." The times were not altogether propitious for the establishment of a regular professorship, but at the beginning of the next year Mr. Walter was requested to deliver voluntary lectures. These lectures he continued to give from time to time, and his name appears in the Journal of the Institute, to which he frequently contributed as "Professor of Architecture."

He fully appreciated the dignity of his art, and from the first his pen and his public utterances all tended to one end—its elevation and the cultivation of high aspirations among its practitioners. Thus, in 1841, he writes:—"If architects would oftener aim to think as the Greeks thought, than do as the Greeks did, columnar architecture would possess a higher degree of originality, and its character and expression would gradually become conformed to the local circumstances of the country and the republican spirit of its institutions." Among the articles in the Journal which appeared from his pen during these years may be enumerated the following:—"Architecture in the Middle Ages," "Formation of an Artificial Spectrum," "Orders of Architecture," and general articles under the head "Architecture"; elaborate reports and descriptions of the designed constructions of the County Prison and of the Girard

\* A paper by Mr. G. C. Mason, read at the convention of the American Institute.

College (which he was then building from his own designs), besides numerous other articles.

Mr. Walter's professional practice rapidly increased after his design for the Girard College for Orphans was adopted in 1833, the corner-stone of which building was laid on July 4 of that year. When the structure was complete in 1847 he was elected one of the Board of Directors for the college, and served in that capacity for three years. In 1838 the Building Committee of the college sent Mr. Walter to Europe for the purpose of "Examining the practical workings of the various devices and appointments for health, convenience and comfort, in the principal seats of learning in Great Britain and the Continent," with a view to derive such information on these subjects as would be likely to prove useful in fitting up and furnishing the building of the college.

We must now refer to an event which advanced architectural development and was the beginning of systematic and united methods of architectural practice in the United States, viz, the attempt in 1836 to found an American Institution of Architects. At that time there was only a little over a half-score of properly trained architects in the country. These gentlemen met in the city of New York on December 7, 1836. Mr. Walter was one of the pioneers and most active promoters of the movement, and of the group of architects who met on that day one alone remains, Alexander J. Davis, the architect of the University of the City of New York and of many other important edifices, and now a corresponding member of this Institute. A draft of a constitution was formulated, and the members adjourned to meet in Philadelphia on the first Tuesday of May 1837. The circular calling for this meeting, dated March 23, 1837 (a copy of which interesting document hangs in the office of the Institute in New York), was signed by Thomas U. Walter, secretary.

The meeting took place at the Pennsylvania Academy of Fine Arts, but it embraced only a handful of members, and it was found that they were too much scattered for mutual sustenance and the strength necessary for a brotherhood.

The Institution struggled for a while, flickered, and was apparently quite extinguished, though it was really from its ashes that our present Institute, Phoenix like, sprang.

Mr. Walter's position was soon assured, as his merits were appreciated by numbers of influential citizens, who rewarded him with their patronage, by confiding to him the designing and construction of noble works built in the pure Classic style of which he was the most strenuous advocate and enthusiastic student.

In the early days of his successful practice it was generally the custom in Philadelphia to have the dwelling and office of architects in the same building or adjoining each other, and thus there was a more intimate and friendly acquaintance between the students and the preceptor's households than in these times. Mr. Walter was always affable and kind towards his students, and always took pleasure, during his leisure moments in the office, in lectures to them and imparting knowledge in practical and æsthetic subjects; but, although he had many during his early career, most of them lacked the patience and perseverance necessary to acquire the requisite knowledge to become successful practitioners, and eventually drifted into other pursuits.

Among Mr. Walter's works of private practice may be enumerated the St. George's Hall, the Preston Retreat, the Debtors' Apartment, the Philadelphia Savings Bank, and several churches in Philadelphia, the Chester County Bank, the Biddle and Cowperthwaite villas on the Delaware river, and other buildings in the country. But all these creditable labours were but the training and leading up, as it were, to the one great work with which his name must ever be associated—the extension of the National Capitol at Washington, together with the noble dome which surmounts and dignifies its mass.

The appointment of Mr. Walter as architect to execute his design for the extension of that truly noble building was made by President Fillmore, in 1857. It was well merited, for, of all American architects of that date, Mr. Walter was the best fitted by steady and innate love for the purest types of Classic architecture to grasp successfully the problem of the Capitol extension, and to design the dome with which he later glorified and crowned his work. The boldness of his composition evinces his skill as a designer and his confidence in himself. The vast wings forming the extension are of white marble of treat hardness and durability. They have taken upon them with years a delicate pearly colour, which, as it shows itself in the long colonnades, gives them an effect of purity and beauty.

Much as we pride ourselves upon the advances made in architectural design, we have nothing to show more nobly simple and well studied than this, the grandest of Mr. Walter's works. Such is the verdict of the architect and the critic.

Ferguson, the historian of architecture and often a severe censor, writes:—"Taking it all in all, however, there are few buildings erected in modern times which possess to a greater extent than the Capitol at Washington appropriateness of

purpose combined with the dignity necessary for the Senate House of a great nation. It has not the variety and richness of detail of our Parliament House, but it is a far statelier building, and its faults are those of the age in which it was commenced, and which here tied the hands of subsequent architects, and prevented them from using the improvements that have since been introduced in the arts of design; but it wants but very little to enable it to attain to very high rank amongst the buildings of its class in other parts of the world."

The Hon. J. H. B. Latrobe, son of the architect of the original Capitol at Washington, Benjamin W. Latrobe, thus eulogised Mr. Walter, in an address before the American Institute of Architects in the city of Washington, at its fifteenth convention in 1881. Speaking of the extension of the Capitol, he said:—"I can scarcely speak in his presence (President Walter being in the chair at the time) as I would like to speak, could I find words to do justice to the last architect of the vast pile that now looks down upon the Federal city. The pupil of Strickland, as Strickland was the pupil of my father, it has been with me a pleasing fancy for more than a quarter of a century to believe that there was, in a faint way, a law of descent, applicable under the circumstances, which connected the architect who clothed Thornton's skeleton with sinew and muscle and beauty, until the whole creature became his own, with his brilliant, refined, and accomplished successor, who, at the head of a profession socially to-day without a superior, has absorbed all that has been done before in what is now the Capitol; who, making the magnificent dome, on whose iron sheets the hammer never ceased to ring during the war that threatened to make the whole structure worthless, has screened the exterior littleness of a vitiated taste, and made even the incongruities of the Italian Renaissance subserve the purposes of genius."

Ill-health compelled Mr. Walter to resign from the service of the Government on June 1, 1865, and he then returned to Philadelphia.

Among the important works that Mr. Walter executed in Washington for the Government between 1865 and 1875 are:—The extension of the Patent Office, the repairs of the Congressional Library, the extension of the Treasury building, the General Post Office extension, the Government Hospital for the Insane.

In 1849 the honorary degree of Master of Arts was conferred upon Mr. Walter by Madison University, N.Y. In 1853 the University of Lewisburg, Penn., conferred upon him the degree of Doctor of Philosophy, and in 1857 Harvard University gave him the degree of Doctor of Laws. He also became a member of the American Philosophical Society of Philadelphia. In 1860 he delivered a course of lectures on architecture at Columbian College, D.C., and also in Philadelphia and vicinity.

Dr. Walter was now well advanced in years and full of honours. After his return from Washington he engaged in but little private practice. When the erection of the new City Hall in Philadelphia was commenced, he became connected with Mr. John McArthur, jun., the designer and architect of that building, and continued to assist him on its work until a short time before his death.

Of Dr. Walter's connection with the American Institute of Architects, the profession may well be proud. The original Institution of Architects had slumbered for nearly twenty years when the present Institute was founded in 1857, and on February 23 of that year Dr. Walter was elected a Fellow. On the retirement of its first president, Richard Upjohn, in 1876, he was elected its president, which office he filled continuously until his death.

At his last election to the presidency, on December 2, 1886, he thus expressed his thanks to the convention; the words, simple and touching, are not to be forgotten by those among his active associates in Institute work who heard them, and seemed to them prophetic of the great change so soon to come upon him.

"I return you my thanks, gentlemen, for your kindness and for your forgiveness. You might have done better all the time, but I began with you almost at the beginning and have been in my place as often as it was possible, and have done the best I could; and I intended when I came here to decline a re-election, but my friends here have been very kind, and have asked me to agree to it if re-elected, and I have agreed to it for another year. After that, if I live that long, I will ask you to allow me to take a rest. As to the year before us, I promise you to do all I can for the promotion of the prosperity of our profession, here and everywhere—for the promotion of the interests of our Institute. Everywhere and at all times I am yours, asking you to look over my imperfections and to enable me to feel still further that I have your assistance in all matters connected with our profession. I am deeply interested in them and have been so for nearly sixty years. I shall not be troubled that way sixty years longer. Accept my thanks, I pray you."

We have thus followed the career of Dr. Walter from youth

to revered old age. His position in American architecture is a proud one. As he modestly puts it himself in the above address, "I began with you almost at the beginning, and have done the best I could."

As an architect and scholar, Dr. Walter's professional learning was deep and well digested. In style of architectural composition, pure, artistic, and dignified. In social life he was ever the cultured gentleman. In personal appearance, venerable and commanding. "Truth in art" was the keynote in his professional career—the fundamental law which he laid down for himself and the burden of all his writings and public utterances. "Let us live," he once said, "for the promotion of our art. Let us leave no stone unturned to devise throughout the world the elements of a pure and correct taste."

One more quotation from Dr. Walter's address to the Institute of Architects and I will close this memoir. The last words of his annual address of 1880 speak the whole life of the man; no stronger or more heartfelt words could come from the lips of the Nestor of American architects:—

"We owe it to our country, to the age in which we live, to our families, to ourselves, to devote the rapidly fleeting hours of our lives to the accomplishment of the greatest possible good in our vocation; ever seeking to discharge our duties in all good conscience towards those whose interests are entrusted to our care, towards co-workers in the realm of art, and towards Him in whom we live, and move, and have our being."

### RESTORATION OF THE DOGE'S PALACE.

A CORRESPONDENT of the *Scotsman*, writing from Venice on November 6, says:—The great work of restoring the exterior of the Doge's Palace at Venice, which has extended over more than a dozen years, was completed the other day, when the last bit of scaffolding was taken down. As everyone knows, two rows of marble columns and Gothic arches, one row above the other, run round the two main façades of the Palace, that towards the Piazzetta and that towards the Riva Deglia Schiavoni, and upon these rest the lofty massive walls of the building. The whole fabric depends for its stability on the soundness of these ranges of shafts and arches. If they gave way ruin must be the speedy result.

It was amongst these that decay had not only begun to work, but had made serious havoc, so much so that unless this work of restoration had been accomplished this palace, unique amongst the buildings of the world, must have gone to pieces.

I had lately the good fortune to visit the works under the escort of one in charge, and of having the methods of restoration explained to me. He showed me scores of massive shafts and capitals all cracked and shattered. In many cases their separated pieces were only held together by strong bands of iron. He told me how these noble monoliths had been thus split and rendered useless. It had been brought about partly by the Great Fire of 1574, and partly by the oxidising and consequent swelling of thick iron bars that penetrated them just beneath their capitals. In all 116 of such damaged shafts have been removed, and new ones put in their places. In the removing of each one of these the greatest care had to be taken lest any giving way should take place in the walls above. By careful propping this was happily avoided. One of the most masterly removals and replacements was that of the shaft which supports the "fig-tree" angle of the palace. Here it was found that even the oaken piles on which the shaft stood required renewal. The work was accomplished without a hitch. By the use of copper and gutta-percha the evil of rusting in the new bars has been dealt with. The decorations of the capitals have been reproduced with the utmost exactness. Only skilful sculptors were employed, and an art committee scrutinised every stroke of the chisel. I know that in one case where a face had been knocked off a capital and lost, the committee met time after time to consider, not its character, for that was known perfectly from others on the capital, but simply the exact way in which it had originally been set. All the antique columns, capitals, and stones have been arranged and catalogued, and will be carefully preserved in the palace itself, so that reference to any original piece of work can be made at any time. The Venetians are proud that not a single accident occurred during these many years of labour, and they are to be congratulated on the completion of this great work, which restores to something of its original solidity this palace, which belongs, not to Venice, but to the world.

### NEW BUILDINGS.

**Oldham.**—The Oddfellows' Hall, an unpretentious building, which takes the place of the present club in Union Street, has been designed in the Renaissance style of architecture, and although it does not pertain to any great architectural beauty, yet it will vie in design with any other public structure in the immediate vicinity. On the ground floor are three lodge-rooms, each measuring 24 feet 9 inches by 12 feet, and a small

concert-room, 23 feet 6 inches by 21 feet 6 inches, the whole being fitted up with lattice seating. The billiard-room, which is also on the ground floor, provides accommodation for two billiard-tables, and, like the lodge-rooms, is fitted up with lattice seating. The bar is centrally situated, adjoining to it being the smoke-room, which measures 16 feet by 11 feet 9 inches. Two broad staircases, of easy ascent, providing ample means of egress in case of panic, lead to the assembly-hall, 64 feet 6 inches by 36 feet, on the first floor, of lofty proportions, and with coved and panelled ceiling constructed on the best acoustic principles. A large platform extends across one end of the hall, and is immediately connected with the ladies and gentlemen's retiring-rooms placed on both sides of the hall. The hall itself is well adapted for public meetings, balls, concerts, or parties, the exits well arranged, and the acoustics good, and the heating and ventilating carried out on the best principles. A private staircase is provided for the convenience of speakers, and the floor of the hall is fireproofed, being carried by longitudinal rolled-iron girders and small girders running at right angles, the space between being filled in with concrete boarded over. In the basement are kitchen heating cellar, &c., with hoist to carry articles from the basement to the ground or first floor. The building is faced externally with local stock bricks, relieved with Ruabon terra-cotta and sandstone dressings, the roofs being slated with Welsh slates, capped with Ruabon ridge tiles. The contract for the work was let to Mr. E. Stephenson, the sub-contractors being:—Mason, Mr. A. Staley; joiner, exors. of E. Whitaker; slater, Mr. Jos. Jackson; plasterer, Mr. F. Kelly; concreter, Mr. Lowe, Farnworth; plumber, Mr. Bates. The heating apparatus has been supplied by Messrs. Scott Bros., Oldham. The plans have been prepared and the work erected under the supervision of Mr. A. Banks, architect, Union Street Oldham.

### CHURCH BUILDING AND RESTORATION.

**Hindlip Church.**—This church has been reopened after being restored and enlarged. The church will now contain seats for 138 persons, being 40 more than before the enlargement. Mr. Lewis Sheppard, of Worcester, is the architect, and Mr. Collins, of Tewkesbury, the builder.

**Guildford.**—The church of the Holy Trinity has been reopened after extension by the addition of chancel, transepts, and organ chamber. The work has been carried out from the designs of Mr. A. W. Blomfield.

### GENERAL.

**Sir Richard Wallace** has consented to lend a large portion of his collection of pictures to the Royal Academy this winter for the Old Masters Exhibition. A collection of pictures by the late Frank Holl, R.A., will also be exhibited.

**Funds** are being collected for the purchase of pictures for the art gallery in the town of Dudley, with a view of making that institution a permanency.

**The Governors of Heriot's Trust** have received a report stating that the total cost of the building and fitting up of the Hospital School and Technical Buildings and the Heriot-Watt College had been 49,085*l.*, and that that sum had been paid out of the stock of the hospital without borrowing a penny.

**Mr. Ernest Day**, architect, has been elected Mayor of Worcester.

**Mr. Fred Chancellor** has the distinction of being the first Mayor of Chelmsford. Mr. Frank Whitmore, who had carried out the duties of that office as provisional Mayor, presided over the meeting at which the election took place.

**The Paddington Vestry** intend to obtain plans and specifications to enable them to proceed with an application to Parliament for a license to supply the electric light for public and private purposes throughout the parish.

**The School Board for New Kilpatrick** have approved of plans for the extension of Milngavie School, at an estimated cost of 720*l.*

**New Technical Schools** at Shipley were opened by the Master of the Clothworkers' Company on Tuesday. The schools have been built at a cost of 11,000*l.*, and in addition to this the Governors found themselves with a deficit of 4,000*l.* in connection with last year's exhibition. After deducting the subscriptions received, there was still a deficiency of 12,000*l.*

**Llandaff** has just been lighted with gas for the first time, being probably the last city in the kingdom which retained the old-fashioned system of lighting.

**A New Church**, built from the designs of Mr. T. G. Jackson, has been opened for the chapelry of St. Peter's, in the parish of Bishop Waltham. It adjoins the old building, which is to be pulled down.

**CRIMINAL PROCEEDINGS**, under the new Merchandise Act, will be instituted against any person falsely representing any form of ventilator to be a Self-acting Air-pump Ventilator, said title being registered and our Trade-Mark, applicable only to ventilators manufactured by us. Any infringement renders the person infringing liable to two years' imprisonment. ROBERT BOYLE & SON, Ltd.

### EDITORIAL NOTICES.

*The authors of signed articles and papers read in public must necessarily be held responsible for their contents.*

*No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.*

*Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.*

### TENDERS ETC.

As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 p.m. on Thursdays.

Correspondents, when writing to notify an extension of time, or an alteration of the date of sending in Competitions or Contracts, are requested in their letter of advice to write at the head of the required change—"Contract Reporter to THE ARCHITECT."

### NOTICE TO THE PUBLIC.

By the Post Office arrangements THE ARCHITECT can now be sent to any part of the United Kingdom by an affixed Halfpenny stamp; hitherto the postage has very frequently been twopenny per copy. The Publishers will be happy to forward, for 20s. per annum, post paid, THE ARCHITECT, to residents in towns and neighbourhoods to which there is no easy access by railway. Terms for the half-year, 10s.

Our readers are invited to address us on subjects of interest to themselves or the public. We shall be always ready to insert letters asking for a solution of any suitable questions to a professional or practical nature, and to receive replies of such inquiries.

### COMPETITIONS OPEN.

CARLISLE.—Designs are invited for Board Schools proposed to be built in Ashley Street. Premiums of 20% and 10%. The Clerk to the School Board, 27 Lowther Street, Carlisle.

CHERITON.—Nov. 29.—Premium of 50% is offered by the Guardians of Elham Union for the best method of Sewage and Rainwater Disposal. Mr. R. Lonergan, Saltwood, Hythe, Kent.

FOLKESTONE.—A premium of 50% is offered for the best Plan for dealing with the Buildings and Grounds of the Art Treasures Exhibition for Pleasure Gardens. Mr. Alfred H. Gardner, Solicitor, Folkestone.

SCARBOROUGH.—Designs are required for Laying-out Weaponess Valley Estate. Premiums of 150% and 50%. Mr. Joseph Patch, Borough Surveyor, Town Hall, Scarborough.

### CONTRACTS OPEN.

ASHTON-UNDER-LYNE.—For Extensions and Alterations to District Infirmary Wards. Messrs. T. D. & J. Lindley, Architects, Ashton-under-Lyne.

BLACKHILL.—Nov. 24.—For Building Small Farmhouse, &c. Rev. J. J. Cundhill, Muggleswick Vicarage, Blackhill, Durham.

BOOTH TOWN.—Nov. 16.—For Building Six Houses, Mr. Joseph F. Walsh, Architect, Waterhouse Chambers, Halifax.

CHILBOLTON.—Dec. 1.—For Building House. Mr. John Hillary, Architect, Longparish, Hants.

CLEATOR MOOR.—Nov. 16.—For Altering No. 45 High Street. Mr. J. S. Moffat, Architect, 53 Church Street, Whitehaven.

CLECKHEATON.—Nov. 26.—For Erection of Public Baths. Mr. R. Castle, Cleckheaton, and Mr. W. H. Howarth, Cleckheaton, Joint Architects.

COVENTRY.—Nov. 17.—For Building Liberal Club. Mr. H. Quick, Architect, 28 Hertford Street, Coventry.

DOVER.—Nov. 24.—For Building Premises, Cannon Street, for Messrs. Wright Bros. Messrs. Cresswell & Newman, Architects, 54 Castle Street, Dover.

DUBLIN.—Nov. 21.—For Boundary Walls and Alterations to Auxiliary Workhouse, Cabra. Mr. T. H. Alkinson, Clerk to the Guardians, North Dublin Union, North Brunswick Street, Dublin.

EARLSHEATON.—Dec. 10.—For Building Power Loom Sheds, Engine and Boiler-houses, and Long Chimney. Mr. F. W. Ridgway, Architect, Church Street, Dewsbury.

FINSBURY.—Nov. 16.—For Construction of Underground Urinals, Water-closets, &c., South Place. Mr. H. Blake, Sewers' Office, Guildhall, E.C.

HASTINGS.—Nov. 30.—For Building Mixed School and Offices at Ore. Mr. F. H. Humphreys, Architect, 6 Trinity Street, Hastings.

LANDPORT.—Dec. 4.—For Erection of Stands, &c., in Drill Hall, for the Annual Tournament. Mr. A. H. Bone, Architect, Hanover Street, Portsea.

LEEDS.—Nov. 21.—For Altering Two Houses into Three Houses and Two Shops. Messrs. J. Charles & Sons, Architects, 98 Albion Street, Leeds.

LEIGH.—Nov. 31.—For Alterations to the Town Hall, for the Leigh Local Board. Mr. J. C. Prestwich, Architect, Leigh.

LEIGH.—Nov. 31.—For Painting, Paperhanging, Decorating at the Town Hall, for the Leigh Local Board. Mr. J. C. Prestwich, Architect, Leigh.

NOTTINGHAM.—Nov. 19.—For Erecting Additional Workshop and Alterations at the Union School. Mr. A. H. Goodall, Architect, Market Street, Nottingham.

PITSLIGO.—Nov. 26.—For Building Parish Church. Messrs. Matthews & Mackenzie, Architects, 255 Union Street, Aberdeen.

PORTSMOUTH.—Nov. 21.—For Building Quarters for Aged Married Couples at the Portsea Island Union Workhouse. Mr. Archibald H. Ford, Architect, High Street, Portsmouth.

ULVERSTON.—Nov. 16.—For Building Candle Manufactory upon the Ellers Paper Mill Premises. Messrs. J. W. Grundy & Son, Architects, Central Buildings, Ulverston.

WINCHMORE HILL.—Nov. 23.—For Two Additional Pavilions and Additions, &c., to Administrative Block, Northern Hospital. Messrs. Pennington & Bridgen, Architects, 8 John Street, Adelphi, W.C.

## WARRENPOINT.

For Supplying and Fixing the "Efficient" Small-pipe Heating Apparatus to Wesleyan Chapel.

E. BOYES & CO., Liverpool and Newry (accepted).

## TRADE NOTES.

AN important addition has just been made to St. Jude's Church, Sheffield, in the form of a handsome brass eagle lectern of conventional design. This was supplied by Messrs. Jones & Willis, of Birmingham and London.

THE Borough Hall, Oldham, is ventilated by means of Shorland's inlet tubes, supplied by Mr. E. H. Shorland, of Manchester and London, Mr. Sidney Stott, of Oldham, being the architect.

AT a town's meeting at Burnley on Tuesday evening it was decided to promote a Bill for the extension of the borough, and obtain powers to expend 30,000l. on local gasworks and other improvements.

SEVENTEEN tenders were received for heating the Hornsey Local Board Isolation Hospital, and that of Mr. George Jennings, of Stangate, Lambeth, has been accepted for a total of 380l. No decision has, however, been arrived at with regard to the tenders for heating the Board's offices.

ON Monday evening the first instalment of the improvements now being carried out in connection with the electric lighting system were used in Leamington. Arc lights, ranging from 300 down to 50 candle-power are placed at intervals along the Parade, giving a good light, but their brilliancy detracts from the power of the ordinary electric lights.

SINCE the "Popular Educator" first appeared, the firm of Cassell & Co. has grown to great magnitude. But naturally there is a feeling of affection for the publication which, from meeting a want of the time, helped towards the success of the publishers. Although we have Board schools and technical colleges, the "Popular Educator" has not been superseded. It still remains the most successful of all attempts to give valuable information at the cheapest rate. A new edition is now brought out which is no mere reprint, for every page has undergone revision. As the previous editions have been appreciated, it is only fair to assume that the rising generation will also study a work which must benefit every one who studies its pages.

AN inquiry has been held at Eccles as to the application of the Barton and Eccles Local Board for sanction to borrow 10,170*l.* for works of private street improvement, and 250*l.* for the erection of sheds, store-room, and boundary wall at the town hall.

### THE IRONWONGERS' EXHIBITION.

A VERY fair number of exhibits are collected in the above Exhibition at the Agricultural Hall, and many well-known firms are represented. We notice a particularly good show of wrought-iron work, and amongst other firms are Messrs. Edgar Keeling, Teale & Co., of Elm Street, Gray's Inn Road, who show a variety of chandeliers, candelabras, grills, &c., nearly all reproductions of designs previously executed. That excellent finish which is the conspicuous feature of English wrought-iron work is well illustrated by this firm; the designs are charming and novel.

English smith's art is conspicuous at the modest but tasteful stand of Messrs. T. F. Pinnock & Co., and their exhibits show that they are quite cognisant of the sympathetic nature of their material. The heavy work on view, in the shape of two pilasters, is a good instance of clean forging and fitting in the working out of an excellent design. The general effect of this work is, no doubt, produced by the care given to the "sizing" of the iron, a most important feature in the production of a taking effect for the eye. Messrs. T. F. Pinnock have erected a forge at the Exhibition, and workmen are engaged in making the wrought-iron work in all its branches.

Messrs. Kaye & Sons exhibit their well-known push-and-pull system of works, and show its application to theatre exits. The Royal Music Hall and the Court Theatre have adopted it; and we think it has no superior in the market.

Messrs. Darby & Co., Limited, Caledonian Road, exhibit a new method of heating by means of oil and water, which we shall refer to in a subsequent issue. Mr. Robert Adams exhibits his well-known "Victor" door spring, which is so favourably known. The Atkinson gas engine deserves special mention for economy and efficiency. Prominent amongst the lighting firms represented are Messrs. Siemens, with their regenerative gas lamps, of which system they are the originators. The Blackwall Galvanised Iron Company, Limited, Corbet Court,

Gracechurch Street, introduce a speciality consisting of pedestals made of corrugated iron in exact imitation of majolica and marble of every colour. So striking is the resemblance that the firm find it necessary to inform visitors in a printed notice that these productions are not marble. The Scandinavian Stove Company, of 47 Shaftesbury Avenue, exhibit their patent Scandinavian stove—an improvement which should interest those who advocate smoke abatement, for it is practically smokeless.

Mr. F. Benson, of 59 Upper Street, and Highbury Iron-works, Station Road, makes an extensive show of the various kinds of iron wine bins manufactured by him. The French pattern bin, being made in sizes to hold from one dozen and upwards, struck us as being the kind best adapted to the use of those whose houses have not been arranged with cellar accommodation, or those who go in for varieties in their vinous consumption, inasmuch as every bottle has a separate rest, and can be taken out without disturbing the others. They are also made with doors to lock up, so that a wine bin can be placed in any part of the premises with perfect security. Altogether, we conclude that these bins, from their great usefulness and portability, ought to form a very necessary adjunct to the ordinary stock of a furnishing ironmonger, their price being so low as to place them within the reach of every consumer. The next thing that we notice is what are termed wrought-iron bins. These are formed by partitions having crossbars at intervals, on which the shelves, composed of strong plates of sheet-iron, supported by bearers of T-iron, rest. These shelves are removable at will. In these bins the lathe is used in turning. The great features of these bins are the saving of space, the ease with which they can be fixed or removed if required. These appear to us to recommend themselves strongly to architects, builders, &c., for use in mansions, clubs, hotels, and wine merchants'. Mr. Benson seems to have made this business a speciality, having been in it since 1862—therefore competent from his long experience to give the best advice to those charged with the arrangement and fitting up of wine cellars.

Mr. Frederick Betts, of 31 and 33 York Street, London Road, has a fine show of marble mantelpieces, tiled grates, overmantels, &c., at stand No. 17, and also a newly-designed cooking range, the "Grecian," which we illustrate. It is specially prepared for the London market, being strong, well finished, and very low in price, and already several large contracts have been secured for the New Year. This range can

be fitted with open fire arrangements of almost any pattern. Besides being economical in fuel, it is thoroughly strong and durable, and handsome in appearance. Mr. Frederick Betts has an extensive stock of marble and enamelled slate chimney-

pieces, tiled grates and hearths at his show-rooms at the above address, where he has one of the largest stocks in London.

Messrs. W. Höffler & Co., of Basinghall Street, E.C., have a representative exhibit at the Ironmongers' Exhibition of their beautiful artistic wrought-iron work. A reference to the sample books of the firm will further show the marvellous power of designing possessed by the firm, in the unlimited variety of charming articles delineated. The same articles are repeated again and again, no two alike, the variety in design being pushed far beyond what one would have thought possible in the staff of a single house of business. Every use that ornamental metalwork can serve has apparently been consulted. In addition to the application to artificial lighting of every kind, including table-lamps, hall-lamps, &c., are numberless objects to serve the most varied of useful and ornamental purposes. Where all is excellent, it would be hard to pick out individual articles for praise above any of the rest.

#### THE ROYAL SCOTTISH SOCIETY OF ARTS.

THE committee of the Royal Scottish Society of Arts have issued a report on the communications laid before the Society during the session 1887-1888. The committee state they have awarded the following prizes:—The Keith prize, value thirty sovereigns, to James Hart Robertson, Rochester, America, for his paper on "The Writing Telegraph;" a Brisbane prize, value twelve sovereigns, to D. William Kemp, J.P., John Kirkwood, and James Kirkwood, for "Improvements in shaping ductile metals to form concave, indented, or hollow articles, by the direct application of fluid pressure;" a Hepburn prize, value ten sovereigns, to William Ireland, Buckhaven, for his "New machine for making loops, ossels, or snoods for fishing nets, fishing lines, and other purposes;" and a Reid and Auld prize, value three sovereigns, to William Sturrock, watchmaker, 12 St. Andrew Square, Edinburgh, for his paper "On an electric illuminated time indicator." The committee award a complimentary Keith medal to Alan Brebner, M.Inst.C.E., for his paper on "Modern Harbour Construction;" a complimentary Brisbane medal to William Dyce Cay, M.Inst.C.E., for his paper "On the construction of marine works with concrete bags, and on the plant for their deposit;" a complimentary Hepburn medal to John Reid Rosemont, for his paper "On hydraulic hoists with suggestions for improved structure in the apparatus, and greater economy in the employment of hydraulic power for lifting apparatus with variable loads;" a complimentary Hepburn medal to R. Hedger Wallace, M.R.A.S.E., for his paper on "Agricultural Education;" and a complimentary Keith medal to J. W. Inglis, F.R.S.E., M.Inst.C.E., for his paper "On plantations producing fuel and timber for building purposes, in Bengal and Burma." The special thanks of the Society are also given to the president, Mr. Bruce Peebles, F.R.S.E., for his opening address; to Dr. Sang, for papers; and to Mr. R. Norman Shaw, R.A., London, for his paper on "Patent drain-pipes."

#### BUILDING IN LEEDS.

THE report of the inspector of buildings to the Building Clauses Committee of the Leeds Corporation, for the year ending August 31, gives the following statistics on building:—Total number of plans, 1,847; number of plans approved, 1,480; number of plans rejected, 299; number of buildings (including houses), 5,348; number of buildings approved,

4,612; number of buildings rejected, 736. The 2,058 houses shown upon the 360 plans approved, include—14 villas, 8 semi-detached villas, 620 through houses, and 1,416 back-to-back houses. The 31 miscellaneous plans were for 2 churches, 1 addition to church, 1 chapel, 1 addition to chapel, 7 mission-rooms, 1 addition to mission-room, 6 schools, 6 additions to schools, 3 clubs, 1 savings bank, 1 music-hall, and 1 arcade. During the present year 1,723 houses have been completed and certified for occupation, including 6 villas, 13 semi-detached villas, 620 through houses, and 1,084 back-to-back houses. 586 miscellaneous buildings, and 867 privies and ashpits, waterclosets, trough-closets, and dry ashpits, have been completed and certified. Two informations have been laid before the stipendiary magistrate for infringement of the laws, convictions being obtained in each case, with fines amounting to 3/.

#### THE METROPOLITAN BOARD OF WORKS.

THE *Times* says the Commissioners have unfolded an interesting and remarkable history, which should at least prove useful in directing the attention of the new County Councils to some of the methods in which corrupt officials may obtain profit by sacrificing the interests which it is their duty to protect. It is evident from the whole of the report that the members of the Board of Works, of whom the great majority are definitely acquitted of all suspicion of wrong-doing, did, nevertheless, conduct their business in a manner which afforded exceptional facilities for dishonesty.

The *Daily Telegraph* does not approve of the very mild manner in which Lord Herschell speaks of the moribund Board. It says:—"They entrusted the questions of purchases and contracts, not to a small and responsible body, composed of their best men, but to all the members sitting as a private committee, and not as a public board. At these sittings any member could attend and any member could be absent. Consequently the architects who were on the Board made it their business to attend when questions in which their clients were concerned came on for adjudication, and their unprofessional colleagues accepted, of course, the advice of men whom they regarded as disinterested experts, when, in fact, they were interested parties to the contract. Now this system all round presupposes on the part of the Board either an absolute imbecility if they did not perceive the facilities for fraud they were making, or a general, if not a particular, knowledge of the corrupt transactions carried

on. The blame must, no doubt, be divided. There were honest members of the Board who had no suspicion whatever of the tricks played by the clerks in the surveyors' office and by the outside architects; but then, men so utterly blind to what was going on around them are unfit for any public position whatever; they would be incompetent members of a village vestry. With regard to the keener members of the Board, who could shrewdly guess why their professional colleagues said "Yes" or "No," it is obvious that, though not paid in cash, they were otherwise considered. How could they be harsh to friends with whom, perhaps, they had dined the night before?"

"We now see," adds the same journal, "what was inside that whitewashed sepulchre, the Board of Works. The vestries are notoriously incompetent and corrupt, as the state of the slums attests. It will be the same with the London County Council if public opinion does not keep a sharp eye on this new local parliament. Unless high-minded men of leisure and ability come forward as candidates, we shall have a new horde of hungry vestrymen pushing themselves to the front, eager for free lunches, secret bribery, and indirect pickings of all kinds."

The *Standard* says the interim report of the Board of Works is a disappointing document. The ample powers conferred on the Commission to discover the truth seem to be dissociated from the vigour necessary to enforce the proper lessons. One reflection naturally excited by a perusal of the apologetic paragraphs is, that if a body on which no general censure is pronounced could give rise to such scandals, what might be expected of a representative body really and intrinsically bad? The Metropolitan Board has done great and excellent work, for which it is entitled to lasting credit, and yet its career is marked by defects and transgressions of so serious a nature as to invite the most emphatic disapproval. Its relations with music-halls, theatres, and public-houses have been singularly unfortunate, and have given rise to abuses at which the Royal Commissioners are amazed, though their good opinion of the Board survives it all. Two or three officers and two members are marked out as the actual offenders; but beyond these individual cases the Commissioners find nothing amiss, except, it may be, that some part of the organisation was not so well adapted for the proper execution of public business as it might have been. In short, the public are very much indebted to the Commissioners for the facts they have elicited, but owe them small thanks for the conclusions which they have founded upon them. The forty pages of the Report furnish a most painful

APPLY FOR SAMPLE CARDS AND DESCRIPTIVE CIRCULARS.

*exposé* of scandalous practices carried on over a series of years, and perpetrated with an impunity which could scarcely have been greater had the entire body sanctioned and supported them.

The *Daily News* says:—"There seems to be no evidence that the members of the Metropolitan Board have been themselves corrupt, though some of them get justly and severely rebuked, but they were blind to the corruption which was going on all round them, and were little more than mere servants of their own servants."

The *Globe* considers the report is the sort of document which unprejudiced readers of the evidence were prepared for, and that any expectation which may have been cherished of a sweeping condemnation of the Board either for incompetence or neglect of duty, still more for dishonesty, will be grievously disappointed. It says:—"The people of London may be assured, as the result of a most stringent and certainly not benevolently neutral inquiry, that the splendid works which have improved the metropolis almost out of recognition have not, except in very few instances indeed, been the occasion of anything which can be called jobbery or waste. It would be odd if the experience of thirty years did not suggest some lessons for the future, and the proposals of the Commission that the principle of the Corrupt Practices Act may be applied to transactions between public bodies and outsiders will probably receive general approval."

#### RAILWAY CONSTRUCTION IN JAPAN.

FROM the report of the Japanese Railway Bureau for the past year, which has just appeared, it would seem that, rapidly as it is progressing, railway construction in that country has to meet unusual difficulties, or rather, an unusual number of difficulties, owing to the physical geography of Japan. One line of 205 miles in length involves the construction of sixteen tunnels, 16,000 feet long, and the bridging of eleven rivers. One of these had a velocity in time of flood of 27 feet per second, and in another the brick piers have to be sunk to a depth of 80 feet. A range of mountains is crossed at a height of 1,468 feet. Part of another line ascends to a height of 3,144 feet, and during five months of the year work is rendered impossible by the snow, and sometimes in the summer months an epidemic of cholera has the same effect.

#### FALL OF NEW HOUSE.

ON last Friday afternoon a house which formed the corner of a new row of shops and houses in Great Titchfield Street, suddenly collapsed, when six men were killed and several were injured. For some months past a row of buildings in Great Titchfield Street, Oxford Street, has been undergoing rebuilding by the firm of Oldrey & Son, Kensal Road, Paddington. The buildings erected are substantial three-storey structures of yellow brick faced with freestone, and intended as shops with dwelling-houses above. The last of the set to be completed was that standing on a site formerly occupied by the Queen's Head public-house, with a frontage to Great Titchfield Street, and a wing on Riding House Street, a narrow thoroughfare running parallel to Oxford Street. The building had been roofed over, and on Friday afternoon upwards of twenty workmen—bricklayers, carpenters, painters, and their labourers—were at work on the premises. At about ten minutes to four o'clock the attention of the people in the adjoining shops and houses was attracted by a loud rumbling noise, described by a spectator as similar to several carts emptying loads of stones or bricks, and the air around the new building was obscured by a cloud of dust. When this had cleared away partially, it was seen that the structure was now a shapeless mass of broken timber, woodwork, and dismembered fragments of brick walls. The thoroughfare is so narrow that some of the shop fronts opposite were marked by portions of the falling débris. The inquest began on Tuesday before Dr. Thomas.

Mr. Montague Tench, one of the medical officers of the Middlesex Hospital, deposed that the deceased, Alexander Wain, had died in the hospital, sixteen hours after admission, from internal injuries.

John Clements Richards, general foreman to Messrs. Oldrey & Co., builders, said that the old buildings at the corner of Titchfield Street and Riding House Lane were entirely pulled down, and the new buildings were chiefly composed of bricks, stone, and iron. They commenced the work of rebuilding about nine weeks ago. They had thirty-two men employed on the works, which were to be completed within a given time. The work comprised two houses, 53 and 55 Titchfield Street, but that to be reinstated was only one house, and the one that fell was No. 53. They had completed the house as far as the construction went, and they carried out the work under

# FIRE! FIRE! FIRE!

## GRIFFITHS' "PYRODENE" FIREPROOFING LIQUID

(NON-POISONOUS).

Transparent Liquid for Rendering Woodwork Uninflammable,

Without altering its appearance, and where Painting is not desired, such as Wooden Fittings in Exhibitions, Churches, Pews, Matchboarding, Theatre Scenes, Wooden Stairs, Joists, Beams, Floors, Factories, Stables, Mills, &c., in fact, Structures of an inflammable nature of all descriptions. Acts as a priming for new Woodwork for Paint or Varnish. Also for rendering Theatrical and Ball Dresses, Curtains, Paper, Felt, Canvas, &c., perfectly uninflammable.

Griffiths' Liquid penetrates the pores of the wood. It lasts as long as the wood itself. It prevents Dry Rot and decay in house timbers. It does not crack, peel, or rub off.

It is perfectly innocuous and free from smell. It will keep any length of time. Any one can apply it.

One gallon will cover double that of any other priming.

AND

All Woodwork in new houses should be fireproofed with this liquid, the cost is so trifling in comparison with the preservation of the timber and freedom from risk of fire. If work is desired to be painted afterwards, Griffiths' Pyrodene Paint is best for the purpose.

## GRIFFITHS' "PYRODENE" FIREPROOF PAINT.

READY FOR USE.

NON-POISONOUS.

ALL COLOURS.

This Paint is manufactured for preservative and decorative purposes equally as for its FIRE-RESISTING qualities. The Fireproof Paint and Fireproofing Liquid is used at some of the principal Theatres in the United Kingdom.

#### RECENT TESTIMONIALS.

From Messrs. MAXWELL & TUKE, Architects, 29 Princess Street, Manchester: December 28, 1887.

DEAR SIRS.—We used your Paints in nearly the whole of the works for the Royal Jubilee Exhibition, and with very satisfactory results.

Yours truly, MAXWELL & TUKE.

To Messrs. Griffiths Bros. & Co., Dashwood House, London, E.C.

From S. C. LOWE & SON, House Decorators, 39 Cavendish Street, Stretford Road, All Saints, Manchester: November 22, 1887.

DEAR SIRS.—In reply to your inquiry, we, as one of the contractors for the painting of the Manchester Jubilee Exhibition, which closed on the 10th of this month, have pleasure in stating that both your "Aqual" Paint, and also your "Pyrodene" Fireproof Paint, have given great satisfaction. We found them work easily with a covering power of from 30 to 40 per cent. over ordinary paint. Although applied during intense frost, and having been subjected to an almost tropical summer, followed by the drenching rains of this autumn, they are as fresh in colour and have as firm a grip as when applied, and appear quite unaffected by the nine months' exposure. We consider them, therefore, well adapted for all work in any climate.—Yours truly, S. C. LOWE & SON.

CHEAPER AND MORE DURABLE THAN ORDINARY PAINT.

GRIFFITHS' "PYRODENE" FIREPROOFING COMPANY, Limited,  
4 & 5 DASHWOOD HOUSE, NEW BROAD STREET, E.C., LONDON.

the supervision of an architect, Mr. Miller, and he considered the whole of the work was proceeding very satisfactorily. On Friday morning he was on the works, and he noticed nothing dangerous. Ironwork was used in the building, and the materials generally were good and sound. The roof was put on to the house 55 about a quarter to four on Friday afternoon. Witness continued:—I was in No. 55, in my office, when a clerk came to speak to me, and said I was wanted. On going out of the door, with the intention of going up to the roof of 53, I heard a rumbling noise, and thought that it might be that the large tank on the top scaffolding might have fallen. The bricks and the mortar and all the materials were good, but we had a great deal of wet weather. When the building fell I was at the door of 55. I could not tell the cause of the collapse. The works were being carried out under the supervision of the architect, who acted also as clerk of the works, and they were carried out in accordance with the specifications he had drawn. I could not form any opinion as to the cause of the accident. The district surveyor visited and inspected the works, I should think, about once a week. I believe I have seen him there seven or eight times. The witness, in a severe cross-examination, stated that the house had a foundation of 3 feet of concrete, and it was bound by girders to the adjacent houses in Riding House Lane. The mortar was properly mixed with lime and sand. The materials were good. He worked from the architect's specifications and not from any ideas of his own. He did not consider that the mortar was of such an inferior character that on being pressed in the fingers it crumbled like dirt. Mr. Miller, the architect, had a clerk named Freeman. He might have been more frequently there than Mr. Miller himself. The party wall of the adjacent house in Riding House Lane was underpinned before the footings of the new buildings were put in.

George Winter, a bricklayer, said he had been working on the fallen premises for a month or six weeks. He understood the character of mortar. That used in this building was good mortar. He neither heard of nor saw anything wrong in the construction of the building. At the time of the fall of the building he was at work at the top of the house 53, at a chimney. The house suddenly collapsed, and he came down with the chimney to the bottom. He was but very slightly injured. The whole place seemed to collapse in a moment. He could give no explanation whatever as to the cause of the collapse. He heard no complaint or remark whatever among the men as to the character of the building. He had been for

fifteen years a bricklayer, and would know if the materials were good or bad. He looked upon the building materials at this place as good. He had no idea of how this occurrence took place.

Thomas Robinson, a cheesemonger, residing in Great Titchfield Street, said he was looking out of his window at the time of the fall. He had watched the building day by day, and on Friday afternoon it seemed as if it was nearly finished, when all at once it gave a sort of quiver and suddenly collapsed. In less than a minute the entire building fell. All the men were at work, and when he saw what had happened he rushed down stairs and sent his sons for cabs to take the poor fellows away to the hospital. He was not a builder, but he thought it must have been one of the girders gave way. A police-constable and some other witnesses having given evidence as to seeing the building suddenly collapse, but without being able to give any evidence as to the cause,

The Coroner said he should adjourn the inquiry and have the plan, the specification, and the debris of the building practically and professionally examined with a view, if possible, to arrive at the conclusion as to the real cause of the accident. He pointed out, however, that the magistrates made no allowance for such a purpose, and he had on previous occasions to pay for this professional aid out of his own pocket. On this occasion, however, he was pleased to say that a professional gentleman, Mr. Collins, had kindly undertaken to perform the duty without remuneration.

The inquiry was ultimately adjourned till the 28th inst.

#### BIRMINGHAM MASTER BUILDERS' ASSOCIATION.

THE annual meeting of the Birmingham Master Builders Association was held on Monday night, at the Great Western Hotel, Mr. A. S. Smith (president) in the chair. The annual report stated that the committee were glad to report an improvement in trade generally, and hoped that it would be permanent, and eventually extend to the building trade of the town. The committee had again felt it their duty during the year to call the attention of architects to the unfairness of requiring builders to verify the accuracy of quantities supplied; and upon doing so had been fairly met. In connection with this matter, the committee were pleased to be able to report a growing inclination on the part of architects to use the contract

*This work will be presented to EVERY ARCHITECT whose name appears in "The Building Trades Directory for England, Scotland, and Wales."*

## THIRD YEAR OF ISSUE. THE ARCHITECTS', SURVEYORS', AND ENGINEERS' COMPENDIUM, AND COMPLETE CATALOGUE.

EDITED BY JOHN ED. SEARS, A.R.I.B.A., F.A.S., AND C. STANLEY PEACH.  
ILLUSTRATED BY MAGNIFICENT PLATES.

### IMPORTANT NOTICE.

The next issue will contain a **DICTIONARY OF MANUFACTURERS' SPECIALTIES**, and the Editors will be pleased to receive particulars or catalogues of goods, with the leading specialties marked. Names of approved specialties are inserted **WITHOUT CHARGE**. The special feature of the work is **THE COMPLETE CATALOGUE**, in which detailed and priced particulars of goods, with each article indexed, are brought together and classified for the reference of Architects, Contractors, and others.

### TESTIMONY OF MANUFACTURERS.

**NOTE.**—Of the Firms who have already taken space, **Seventy** have ordered from 1 to 8 pages and upwards each, and the following and others have taken greatly increased space:—

D. Bostel, 1 page (increase from  $\frac{1}{2}$  page).  
Broad & Co., 8 pages (increase from 1 page).  
Burt & Potts, 2 pages (increase from  $\frac{1}{2}$  page).  
Doulton & Co., 2 pages (increase from  $\frac{1}{2}$  page).  
Maw & Co., 2 pages (increase from  $\frac{1}{2}$  page).  
Richardson, Ellison & Co., 2 pages (increase from  $\frac{1}{2}$  page in first and 1 page in second issue).  
S. Saunders, 1 page (increase from  $\frac{1}{2}$  page).

J. Wright & Co., 2 pages (increase from  $\frac{1}{2}$  page).  
Hitchins' Fireproof Plastering Co. write:—"Was of great service to us. We can distinctly trace several good orders to it."

James Brown writes:—"Has resulted in business with several firms in the course of the year."

Thos. Gregory & Co. write:—"We have proved its worth." "We find that a great benefit has accrued to us from this excellent method of advertising."

### SPECIMEN OPINION OF ARCHITECTS.

R. Norman Shaw, Esq., R.A., &c., writes:—"I am quite certain it would be of the greatest value, and secure universal support. Manufacturers' Catalogues are of very little use, and go freely into the waste-paper basket, as they are so numerous that it would be impossible to keep them, and unless kept systematically they would be of no use. At least, I know when I set to work to find a name or address I rarely succeed."

Full particulars of JOHN E. SEARS, 16 NEW BRIDGE STREET, LONDON, E.C.

forms which had been approved by the Royal Institute of British Architects, and the National Association of Master Builders. A copy of this form of contract had during the year been sent to each member of the Association, and its adoption was strongly urged. The balance-sheet showed total receipts for the year 81*l.* 9*s.* 7*d.*, which, with the balance from last year, 14*l.* 8*s.* 4*d.*, made a total of 95*l.* 17*s.* 11*d.*; and the various disbursements amounted to 83*l.* 14*s.*, leaving a sum of 12*l.* 3*s.* 11*d.* to the credit of the Association. The report having been approved, Mr. Bowen moved, and Mr. C. H. Barnsley seconded, the re-election of Mr. Smith as president. In reply, the President said that he was deeply indebted to Mr. Bowen and Mr. Barnsley for the services they had rendered to the Association during the year, in consequence of his own illness. The thanks of the Association were due to the gentlemen named. On the motion of the President, seconded by Mr. A. Smith, Mr. C. H. Barnsley was elected vice-president. The treasurer, Mr. W. J. Whittall, was re-elected, as were also Messrs. Barnsley and Sapcote as auditors. The Secretary drew attention to the question of the proposed reduced subscription to the National Association of Master Builders, and pointed out that it was a matter left over from the last meeting. He did not know whether it was intended to proceed with the question. Mr. Bowen said that the National Association carried out its work as economically as possible compatible with efficiency, and he recommended that the matter should pass by at least for another year. Mr. Barnsley considered that if the matter were left in the hands of the committee it would be satisfactorily arranged. The matter then dropped, and the proceedings terminated.

The members subsequently dined together, under the presidency of Mr. A. S. Smith. The loyal toasts having been honoured, Mr. C. H. Barnsley proposed "The Town and Trade of Birmingham." Councillor Barclay, in reply, briefly touched on the progress of the town during the last twenty-five years. He hoped that the improvement which had been felt in several trades would extend to the building trades. The President proposed "Success to the Birmingham Master Builders' Association," and said that in the past the Association had rendered valuable services to its members. Although there was a lull at the present, there might again come a time when its services would be of value of the highest importance. It always looked after the well-being of the members. Mr. Doubleday responded, and contrasted the appearance and importance of the town 300 years ago with that of the present time. The pro-

gress of the last fifty years had been most marvellous, and the buildings which had been erected in the town bore evidence of the progress of the times. Mr. Sapcote proposed "The National Association of Master Builders of Great Britain," coupled with the name of Mr. J. Bowen. The latter, in reply, dwelt on the importance of fidelity to the Central Association, by which means, he contended, the local builders would derive not only benefit to themselves, but would command the congratulations of the town. Several other toasts were proposed during the evening.

### THE STREET ARCHITECTURE OF MANCHESTER.

AN important discussion (according to the *Manchester City News*) on the subject of the street architecture of Manchester took place about a fortnight ago at a meeting of members of the Arts Club, at the Club Room, Albert Square. Mr. J. H. Nodal presided, and amongst others present (in addition to those who spoke) were Messrs. Hermann Magnus, William Mosley, Alfred Kendal, Colonel Rogers, Thomas Black, T. H. McCormick, W. W. Page, William Dawes, S. C. Cawthra, Charles J. Maycock, W. Wareing Faulder, and J. Buchmann. Letters were read from several gentlemen who were unable to attend the meeting. One was from Lord Egerton of Tatton, who, the Chairman remarked, had a peculiar right to speak upon this matter, not only by reason of his knowledge of the city, but on account of his almost professional experience, he having gone the curriculum of an architect's office. Lord Egerton wrote:—"I shall be very glad to consider how the street architecture of Manchester might be improved. I consider the city itself an hopeless case, but I shall be very glad to support any movement to improve the suburban architecture of Manchester." Mr. W. A. Royle, chairman of the Manchester Society of Architects, wrote:—"I am quite satisfied that a subject of such importance to every individual whose lot is to spend a large proportion of his existence in this unlovely city will be ably discussed, and I hope the result of the meeting will be to initiate a scheme which if adopted would have the effect of preventing any further disfigurement of our streets." Mr. Thomas Worthington and Councillor J. H. Andrews also wrote expressing their regret that they were unable to attend, and their deep interest in the subject set down for discussion.

The Chairman said the subject for consideration that

evening was a somewhat novel one. No meeting of the kind had ever been held in Manchester before, and, so far as he knew, no public meeting had ever taken place in any town in the kingdom to deal with the question of street architecture and its improvement. Consequently there were no precedents to guide them; they were sailing, as it were, into an unexplored sea. It was true that in Manchester we had at times had discussions in the newspapers, and one last year, begun by Mr. Robert Falkner, attracted a large amount of public attention. Unfortunately, like most questions introduced in newspapers, unless backed by an outside movement, the results were nil. We had also in this city two architectural societies, and it was quite possible, and indeed probable, that the members had discussed the subject frequently, but as their proceedings were confined to themselves, they had no influence upon the outside public. The great point of course was to create a public interest in the subject, and, when that was done, no doubt architects would give every aid possible.

Mr. Alfred Darbyshire was called upon to open the discussion. He did not propose, he said, to take up the time of the meeting by discussing what might be called the absurdities which characterised the Georgian era; but he thought they might take some notice of the period which followed it—that of revived Classicism in Manchester. He remembered the existence of an architect who did almost the whole of that work, whose name was Richard Lane, who had been educated in the ultra-Classical school, and who was in fact a student of Greek art and Greek architecture. He could not believe in anything else, and the consequence was he perpetuated many of the Classical abominations in Manchester which unfortunately were so bulky, so heavy, and so costly that they had never yet been removed. The golden age of Pericles still stood out as marking the acme of architecture and sculpture and of art, and therefore in calling these things Classical abominations he (Mr. Darbyshire) was not for one moment wishing to derogate from the beauty and utility of the architecture of the Acropolis of Athens. It was with regard to the misapprehension of the objects of that art and its misappropriation in the streets of Manchester that he wished to say a few words, and which he thought had caused a vast amount of ugliness and unloveliness. He did not know whether it had struck his hearers as it had struck him to ask what had a Greek temple to do with an infirmary, a Quaker's meeting-house, or a concert-hall. It seemed only about a quarter of a century ago that another man arose in Man-

chester, whose name was Edward Walters. He had also had a classical education, but his proclivity fell upon the Italian lines, and they had those beautiful edifices—many of them Manchester warehouses—all built upon the Italian model, and certainly built by a man who knew what he was doing, and who was a perfect master of Italian architecture. He need not enumerate many examples. The Free Trade Hall, of course, was his last and greatest work, upon which Walters expended years of thought. Then they came to the men of our own time, among them Mr. Worthington and Mr. Waterhouse and others, who introduced another phase of art, a good deal of which was beautiful and appropriate; but there was again another stage which had no style and no art about it, so far as he (Mr. Darbyshire) could judge. There was a utilitarian spirit through the whole of the city which prevented in some way or other the realisation of beautiful works of architecture or other street adornment. It seemed to him that the unloveliness of Manchester might be put under a few short heads. The first was bad architecture and worse sculpture: then they had utilitarianism, then misappropriation of site, and then they came to something outside architecture in the way of street advertising, overhead wires, and authoritative restrictions, the smoke nuisance, want of colour and light and shade. If they took bad architecture, they came first to the great building in Piccadilly, and which they knew as the Infirmary. The history of that building was most singular. Originally it was a plain brick building, with a lot of square holes knocked out for light. Then Mr. Lane came and faced it with ashlar, making it look as respectable as he could, and putting a big portico in front, which made the patients' rooms dark, dreary, and miserable. Thinking that was not sufficient, Mr. Lane added a little dome, which was so small and insignificant as to present a decidedly puerile appearance. What had followed? All round the site, in every direction, they saw huge piles of white brick, with certainly nothing but holes knocked out for light, objectionable buildings were placed against the Classical front, and altogether he thought there never was such an unfortunate jumble in any town in the country. He did not know whether a golden age in art would ever come to this country, but if it did the men of that day, he ventured to say, would look with amazement at the waste and spoliation on that site, and wonder what order of men they were that lived in the nineteenth century. He singled this out as one example of the perpetuation of ugliness. Then as to utilitarianism. In the erection of large retail shops they

# Wilson's Patent Dioptrical Pavement Lights.

WILSON & CO. beg to call the attention of Architects and others to the superiority of Wilson's Patent Dioptrical Lenses for pavement and floor lights. These Lenses are constructed on strictly scientific principles, and have been approved by some of the highest authorities on Light. They are made of the Best English White Flint Glass of high refractive power, and transmit more light than any other form of Lens yet introduced. The reflecting surface being spherical, the rays of light are distributed in every direction.

Wilson's  
Patent Lenses  
for  
Floor Lights,  
Deck Lights,  
and  
Pavement  
Lights  
of every  
description.  
Sample Lenses  
on  
application.

Wilson's  
Patent Lenses  
for  
Stall Boards,  
Cellar Flaps,  
Ornamental  
Tile & Glass  
Pavements.  
Safety Coal-  
Plates.  
Plans, Prices  
and Estimates  
Free.

Fig. 1 shows how the ordinary prism or semi-prism, by receiving the rays on a plane reflecting surface, throws them forward at one angle only, in parallel lines close to the ceiling.

Fig. 2 represents the Patent Dioptrical Lens, and shows by comparison how the rays of light, striking on the curved inner surface, are reflected forward through the face of the lens in every direction, filling the whole angle of 90°, thus illuminating the apartment from floor to ceiling and from wall to wall.

From the above diagram it will be seen wherein consists the advantages claimed for Wilson's Patent Lenses. The objection to the semi-prism is that it reflects the light, as shown in Fig. 1, at such an angle as to be of little use, and more especially if the line of the ceiling in below the line of the pavement; then the value of the semi-prism as a light projector is entirely lost.

It will be seen also, on reference to the above diagrams, in Fig. 1 that the first row of semi-prisms obstructs the rays of light from each succeeding row, whereas in Fig. 2 the bulk of the rays of light are projected at such angles as to pass unobstructed into the room.

The correctness of these illustrations can be practically demonstrated to any architect desirous of testing them.

PRICE LISTS AND ESTIMATES ON APPLICATION TO

WILSON & CO., Bridge House 181 Queen Victoria Street, London, E.C.

seemed to have reached an age of glass and iron, of large piles of superstructure resting apparently on plate glass. So long as they could get the means of displaying the goods and accommodation for customers, the front of the buildings and the effects upon the streets were never for once considered. That was what he called an absolute triumph of utilitarianism. Misappropriation of site seemed to him to be an important point to look at. In Piccadilly they had a grand site, but he asked whether the best had been done with that site. The Town Hall was another example. He held that there had been want of judgment on the part of those who settled where that building should be, inasmuch as they had given the architect one of the most awkward problems to solve in giving him a site like a flat-iron to work upon. As a consequence, thousands of pounds had been thrown away, and the architect had been cramped and had not been able to produce the result which the citizens were entitled to expect when they built their grand municipal hall. It seemed to him also that science in these days had played a great part in the ruin of street architecture and street art. They could stick up as many advertisements and ugly flaming placards all over their buildings as they thought fit. They could cover their town with a network of wires and erect excrescences which destroyed the outline of any buildings they might attempt to put up. In fact, there had been no attempt on the part of any authority to guide the hands of the men who had to provide the future architecture of Manchester. As to the sculpture of Manchester, perhaps the least said the better. Sculpture was, perhaps, not a strong point in the streets of any city in this country, but in Manchester, he thought, they had been peculiarly unsuccessful in this respect. He did not think any continental town would tolerate, for instance, the statue of Cromwell, which stood near to the Cathedral. The authority that would allow those four miserable, horrible lamps at the corner of the pedestal of that statue to remain all this time was to blame. There was a case calling for redress and for some body in the city to regulate these things. They had a statue of their late worthy Bishop in Albert Square, and it was an honour to the city that there should be a statue to a Bishop, but it was a misfortune that such a statue should be completely thrown away. He (Mr. Darbyshire) was open to correction, but he would not have allowed the Bishop to stand outside with his hat off. He would have surrounded him or have associated him in some way with that ecclesiastical architecture which was a part of his existence. He would not have put his back to the principal square and compelled

people to walk all round to see the name of the Bishop on the back of the pedestal. These things showed the want of some regulating authority. We were sadly handicapped in England, and in this city especially, by the climate. It seemed to him a vital principle that science should attempt in some way or other to get rid of the vitiating influences to which street architecture was subjected here. He did not despair. He had hopes that a better day would dawn. He supposed they must all admit that loveliness in their streets was of great importance to the poetry of life, and he hoped some action would be taken by which the future of the Manchester streets and their architecture might be regulated. He did not think he could even suggest what should be done; but as long as we had a corporate body to govern the city, that body ought not only to take cognisance of the sanitary state of the life of the citizens, but it ought—either by an individual who knew all about the subject or by a well-constituted and able body of men—to strive, if not to produce loveliness, to prevent ugliness. If that club could give expression to some practical opinion which could go before the civic authority, he could not see why we could not, as they did in the grand old Italian cities, have a man or men who should have the power to say that people who built shops, or warehouses, or anything else, should not build that which was ugly. He did not ask that men should spend money in making things gorgeous, but he asked that the lines and the colour should be good, and that the buildings should be good in other respects. It was as easy and as cheap to produce a beautiful thing as an ugly one, and this was a principle that should not be lost sight of.

Mr. John Farrell said he thought it was as well that non-professional views on the subject should be heard after the eloquent disquisition they had had from Mr. Darbyshire. The only suggestion that seemed to come from Mr. Darbyshire's remarks was the absolute sweeping away of every architectural feature in Manchester. There was scarcely one of the things he admired in Manchester in the way of street architecture that Mr. Darbyshire had not condemned, and very likely given good reasons for condemning. He (Mr. Farrell), however, thought that the architects were not so much to blame. In Manchester they were very seriously handicapped. He did not care whether the buildings were of Greek origin or Italian, or whether the outside suited the inside—the general effect was the only thing they need think about in considering the question. If street architecture was to be of any value at all it should act in the direction of elevating the public taste. There were in Man-

# KALLKOLITH.

## NEW PATENT PRIMING AND STAIN.

*Acknowledged by experts of nearly every country to be one of the most important inventions of the Nineteenth Century.*

PATENTED IN  
England,  
Belgium,  
France,  
Germany,  
Italy.

PATENTED IN  
Austria-  
Hungary,  
Denmark,  
United  
States  
of America.

**KALLKOLITH** is one of the most marvellous inventions of the present age, and is used as a priming in place of the now almost obsolete oil-colour. It produces an exquisite smoothness, combined with great durability, and amalgamates thoroughly with wood, iron, cement, stone, plastering, &c.

**CHEAPNESS.**—It saves at least 100 per cent. in comparison with any other priming now in use, being less than half the weight.

**ECONOMY** is manifested by the fact that one 14-lb. tin of **KALLKOLITH** goes further than three times the same quantity of oil-colour.

**DRYING POWERS.**—It dries within one to two hours, thereby greatly facilitating the quick dispatch of labour.

**DURABILITY.**—Where **KALLKOLITH** is used it imparts an amount of durability to all oil-colours used upon it which has never yet been obtained, and one of the most important advantages in its use is that the paint put upon it does not blister.

**PAPER-HANGING.**—Walls prepared with **KALLKOLITH**, thinned with seven parts of water, give a great additional advantage to the hanging of all descriptions of papers.

### TESTIMONIALS.

21 New Bridge Street, London, E.C.: February 23, 1888.  
I have had some trials made with the **KALLKOLITH** during the past few weeks, the results of which are very satisfactory. The **KALLKOLITH** is to be used as the first coat of paint on wood and other substances, and is of such a nature that the ordinary work in preparing for paint is considerably lessened, and the usual number of coats now given receded, and, once fairly introduced in the market, I am certain there will be a large sale.  
J. WM. STEVENS, Architect and Surveyor.

75 Newman Street, Oxford Street, W.: Feb. 15, 1887.  
We are pleased to tell you that the **KALLKOLITH** supplied to us has been fairly tried, and we find that it answers all that you claim for it.  
CAMPBELL, SMITH & CO.

Price per case of 8 Tins of 14 lbs. each, net 40s., packing included. Special terms to Wholesale Buyers and Shippers.

Address—**KALLKOLITH CO., 175 STRAND, LONDON, W.C.**

chester numbers of exquisite buildings. His complaint was, and it was a complaint against the Corporation directly, that those magnificent buildings were absolutely spoiled by the want of ordinary supervision and ordinary care, and given a character of unloveliness which was common to every one of them. He referred to the point which Mr. Darbyshire himself mentioned—those abominable hoardings which were put about all the principal streets, and which had the effect of destroying any beauty that architects might succeed in providing for the people, and on which capitalists never ceased to spend their money. We had at the bottom of Market Street one of the finest buildings in England, the Victoria Buildings, the work of a member of that club. Of that building Manchester had great reason to be proud, but right in front of it was one of those staring hoardings for beastly placards, and the Corporation made no effort whatever to stop that system of mural advertising. A man put up a house, and spent a lot of money upon it; another man put up a second house within twenty yards, and both these houses were occupied; but there was an intervening space, enough to build a third house upon, of which the mural advertisers—those creators of unloveliness in Manchester—took possession, and paid a magnificent rent for it, in order to disfigure both the house and the whole neighbourhood. He (Mr. Farrell) said that the Corporation should control this. The Corporation of Edinburgh controlled such things in that city. It was stupid nonsense, in his opinion, for the members of the Corporation to contend that they had no power to deal with these things. If they had not it was more to their disgrace, for they could have that power if they applied for it. In the cities of the Continent, and in some of the towns of this country, such disfigurements as he had referred to were unknown, simply because the men who were returned to the municipal body took the precaution to provide themselves with the power to prevent the development of unloveliness and the throwing away of speculators' money needlessly. He thought it was unfair to architects, as well as to capitalists, that the Corporation should permit these things, and he suggested that some power should be brought to bear upon the Corporation to put an end to the system of mural advertising. If that were done he had every confidence in Mr. Darbyshire and the rest of the architects of Manchester being able to make the city as fine and as beautiful, architecturally, as any in the country.

Mr. A. H. Davies Colley, president of the Manchester Architectural Association, said he supposed some fault must rest with architects, but it seemed quite possible to him for the

municipal authority to exercise some kind of influence with regard to the architecture. He agreed with Mr. Farrell that the state of things in Edinburgh was much more satisfactory than it was here, and he thought it was so both in Birmingham and Newcastle. Probably some sort of a board of architects, and, if they liked, of artists too, might be appointed who should have a say as to the general lines of a building, its general suitability to the streets, and to the buildings right and left of it. If some sort of supervision was exercised by a competent board of that kind, he thought a better state of things would be the result. He thought, too, it was quite possible to devise methods of making the slums far more lovely and less ugly than they were now, and also that the city might be made more attractive, at least in the summer, by displays of plants and flowers in tubs, in open places like Piccadilly, Albert Square, and St. Anne's Churchyard.

Mr. John Brooke said he for one did not agree with Lord Egerton's sweeping remark about the unloveliness of Manchester. He thought Manchester was far from unlovely. Any one passing through the city on Sundays or Saturday afternoons, when there was no smoke, must be impressed with the beauty of the outlines on looking down almost any street of the city. He thought there were very few towns in the kingdom where there were more beautiful outlines in the streets. This pointed to one centre that must be attacked, and attacked vigorously, namely, the smoke nuisance. The architects of Manchester had to complain of the want of attention that was displayed to any suggestions made by architects to the Corporation. Such suggestions had been received, if not with discourtesy, with more or less of contempt.

Mr. Robert Falkner (a member of the Art Gallery Committee of the Corporation) said he did not agree with Mr. Farrell that Mr. Darbyshire's remarks had no practical ending. The whole tendency of them was that there was no committee in the Corporation who had any jurisdiction upon the æsthetic appearance of the city. It seemed to him (Mr. Falkner) that as the City Council had outside gentlemen on the Art Gallery Committee, similar aid might be given by competent gentlemen upon this particular subject. The great difficulty which architects had to contend against was the excessive deposit of carbon, and in a few years their buildings were covered with black slime. If that could be got rid of the appearance of the city would be greatly improved. A complaint had been made about the hoardings and placards. The Corporation had upon their hands a large quantity of vacant land surrounded by

NOTE.—All Closets are fitted with the "Weaver" Flush Fan, with Waterfall Action. (The "Weaver" Flush Fan being adaptable to ALL KINDS of Closets, Licenses may be granted to Manufacturers.) The Flush Tanks are noiseless. There is greater flushing and cleansing power than in any other closet. Trappage up to 3in. With a supply of the todote Sanitary Salt to the Tanks, these Closets are odourless. Lead Closet Traps or boarded floors, 7s. 6d. and 10s. 6d. Ball Valves to Flush Tanks for quick filling under low pressures. 4in., 2s. 6d.; 3in., 3s. 6d.; and Stop-cock, 3s. 6d.  
N.B.—The Interceptors and all other Traps are absolutely self-cleansing, and dispense with grease collectors. Illustrated List, also "Instruction in Sanitary Construction" (Domestic Section, abbreviated), and "Memorandum on House Sanitation and the Law of Landlord and Tenant thereon," by R. Weaver, C.E., F.C.S., Sanitary Surveyor, free by post.

The Domestic Engineering and Sanitary Appliances Company, 24 High Holborn, London, W.C.

hoardings, and in the interests of the citizens the hoardings had been turned to account and let to the advertiser until the land was required for building purposes. When that time came the placards would disappear. With regard to the suggestion as to the planting of plants and flowers, he was afraid, as Dr. Tatham, medical officer for Salford, put it in his report, that each year got more hopeless, and he really doubted whether such things would flourish in Manchester until we got something like purity of atmosphere. He hoped, however, that the experiment would be tried. Speaking as a member of the Art Gallery Committee, they—the outsiders on the committee—in their last report intimated to the Corporation that they should be glad to form a body or be consulted upon any points when the æsthetic conditions of the city were under consideration. He was sorry to say that that suggestion seemed to have fallen upon unfruitful ground, for nothing had been brought before them in any shape or form. A point on which he felt strongly, and on which he thought the Corporation was much to blame, was that in laying out new streets like Deansgate they did not leave a square or a circus down the entire length. It was almost a disgrace to the city that the Corporation should have laid out a fine street like Deansgate, from the Cathedral to Knott Mill, without leaving one such open space. That would not have been done in Edinburgh or London. In Deansgate there was ample room for a square or circus here and there, and besides adding to the beauty of the street, the Corporation would have had extended frontages to dispose of. The same remark applied to Market Street, from Piccadilly to St. Mary's Gate; but there they were dealing with what had been done by a former governing body of the city. He hoped the time would come when such things would not be tolerated, and when the Corporation should be compelled to give architects the opportunity of their work being seen.

The Chairman said he was disappointed that members of the architectural profession present had not said a little more about the defects or deficiencies of the building by-laws of the city. The first notion of holding this meeting was due to a remark made on that point by Mr. Darbyshire in the course of a lecture he had delivered in Ancoats. His remark showed that, under the present by-laws, the Corporation not only did not encourage but actually discouraged anything of an architectural character for the beautifying of a neighbourhood. The Corporation had got powers for two things, namely, the superintendence and control of buildings for sanitary reasons, and secondly, for the safety of the public. If they did not possess

powers which could enable them to encourage the artistic side of architecture, the sooner they obtained them the better.

Mr. John Angell said there was no doubt that black smoke could be prevented from entering the atmosphere, and that it could be done cheaply and effectively was shown by the successful system of smoke-prevention which is in operation at Farnworth Bridge, near Bolton, the invention of Mr. Herbert Fletcher.

Councillor Richard Newton, on the invitation of the chairman, addressed the meeting. He said he was not a member of the Improvement Committee, and those who were not on a committee knew very little of what happened in it. He was, however, on the Parks and Cemeteries and Nuisance Committees, which dealt with matters which had been touched upon in this discussion. One was as to the prevention of smoke. About three-fourths of the members of the Nuisance Committee, himself among the number, had had the pleasure of seeing Mr. Fletcher's system in operation at Farnworth Bridge, and it was certain as the result of that visit that something would be done within the next few months to prevent the smoke nuisance in Manchester. An excellent suggestion had been made that evening with reference to the placing of some kinds of plants or shrubs in tubs which should be put down in Albert Square, in front of the Infirmary, and other prominent places in the centre of Manchester. The Parks Committee was on the point of dissolution; but if he was again elected a member of it for the coming year, and it was very likely that he would be, he would take care that the subject was discussed there. The suggestion might be carried into effect without entailing much expenditure. With regard to improvements in the style of our public buildings, well, trade was bad, and a terrible ghost always haunted every man in the City Council who began even to think about the subject. One gentleman had remarked that the Victoria Buildings were a magnificent pile. Members of the Council wished them elsewhere, as they were an unfortunate possession. A good deal had been said about the duty of the Corporation. He had considered the matter, and stood by the opinion that Manchester was as well governed as it deserved to be. If gentlemen would go into any district of Manchester and hold a meeting upon a subject of general interest and importance there were sure to be a very small audience; but get a candidate who could deliver witty speeches, or indulge in personalities about his opponent or if a scandal or row was anticipated, the room would be filled. It was an easy matter to find fault with members of the City

County Council, but it was not reasonable or sensible to do so. Great difficulty was experienced in securing candidates for the seats in the City Council; the post of Councillor went begging all over Manchester, and for every man who gave his consent to be nominated ten had refused. Why was this? It was because gentlemen looked down on the position of Councillor, and as long as such a feeling existed amongst the educated and leisurely portion of the community there would be an ugly city to look at, and rich men would see money wasted on objects that they cared nothing about, and they deserved it. Until the educated, the leisurely, and well-to-do set themselves to perform the serious duty of citizens, and there was less difficulty to induce them to enter the Council, the evils complained of would exist and never be cured. It must also be recollected that members of the Council could never move faster than those behind them in the city. The defect was, therefore, not in the Town Hall, but in the constituencies, and if the people would only stand by and support their representatives, all that was wanted would and could be done.

Mr. Darbyshire, in replying on the discussion, said that it had not been in vain if it had only established that the smoke nuisance could be cured. Following that discovery they could have their trees and their colour, and a thousand and one things that they could not have while the smoke nuisance existed.

### PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

#### APPLICATIONS FOR PATENTS.

15806. Richard Newell, for "An improved method and means for ventilating rooms and buildings." November 2, 1888.

15850. John Allen Smith, for "Improvements in window-fasteners." November 2, 1888.

15879. John Clayton and Charles Tindall, for "Improvements in and relating to water-closets." November 3, 1888.

15899. William H. Kent, for "An improved device for

moving curtains attached to rings hanging upon poles or rods." November 3, 1888.

15920. John Henry Lightbody, for "Improvements in the manufacture of water-cisterns and other analogous articles." November 3, 1888.

16011. James Shepherd, for "Improvements in treads for stairs, steps, landings and floors." November 6, 1888.

16019. Henry Tudor Owens, for "Improvements in mechanism for operating fanlights, skylights, ventilators and other similar movable parts of structure." November 6, 1888.

16053. Charles Huelser, for "A new fireproofing device for walls, ceilings and other objects." (A. Fenton, Germany.) November 6, 1888.

16064. James Cosgreave and Louis Morley, for "An improved vent and shut-off apparatus, for shutting off water from supply-pipes, and for preventing sediment and other impurities flowing from a cistern into the service-pipe." (Complete specification.) November 6, 1888.

16126. Mary Woodward, trading as James Woodward, George Price and Ned Collier, for "Improvements in and in the apparatus for the manufacture of sanitary pipes, and other like socketed or flanged earthenware articles." November 7, 1888.

16129. Joseph Emile Lansard, for "An improvement in the contact makers of electrical alarms for doors and windows." November 7, 1888.

16142. Augustin Hentschell, for "Improvements in apparatus for washing roadways and clearing the snow therefrom." November 7, 1888.

16155. Joseph Thornton, for "Improvements in and relating to domestic and other fireplaces." November 8, 1888.

16169. Francis Fryer Abbey and Allen Walshaw, for "An improved chimney or chimney-pot for the prevention of down draughts." November 8, 1888.

16177. Edwyn John Barker, for "An improved pattern valve or draw-off tap." November 8, 1888.

16182. James Chandler, for "An improved sash-fastener." November 8, 1888.

16185. Arthur James Smith, for "An improved apparatus for dressing white lead and other colours." November 8, 1888.

16197. Moses Bowring, for "Improvements in moulding bricks of fire-clay, and bricks (or briquettes) commonly known as 'Bath bricks.'" November 8, 1888.

16214. John Phelps, for "Improvements in the eaves gutters of roofs." November 8, 1888.

## THE PERFECTUM Is the Most Perfect IRON DOWN SPOUT Ever Made.

Also GREGSON'S PATENT LOOSE CLIPS, for other Makers' Pipes, are the most Useful and Cheapest in the Market. Write for Price List.

Awarded Certificate of Merit by the Sanitary Institute of Great Britain, at the Health Exhibition, Bolton, in connection with the Annual Congress, September 1887.

These Pipes are a perfect protection against damage and disfigurement of outside walls; also of the plaster and paperhangings inside rooms through defective downspouts. They are very easy to fix and renew, because the nails which are always intended to remain in the wall are first driven into a joint within  $\frac{1}{4}$  an inch of the head. The PERFECTUM is quite an improvement on any down-spout hitherto made, it having a 7-inch socket for sliding to wall joints, which saves drilling and plugging, and for sliding out broken middle lengths for renewal without removing others or drawing the nails. It simply hangs on the nails  $\frac{1}{4}$  inch from the wall to convey any escaping water clearly down the pipe, without wetting the wall, and that it may be easily painted all round.

Architects can have a model free of cost on application.

### ORNAMENTAL CLIP.

For Projecting Pipes without Ears by means of a Galvanised Bolt.

On view at the Cardiff Exhibition, September and October, and at the Ironmongers and Metal Trades Exhibition, London, November 12 to 24, 1888.

Telegrams—"PERFECTUM," Bolton.

In London the above are kept in stock by Messrs. GEORGE WRIGHT & Co., 155 Queen Victoria Street, E.C., who will be pleased to show and explain them to Architects and Contractors. They can also be had from J. GREGSON, 17 Bath Street, Bolton, Lancashire, and from the principal Ironmongers and Lead Merchants throughout the country.

The PERFECTUM will be exhibited in the Parkes Museum, London, and at the Glasgow Exhibition.

Terms, Post Free.

## PROVISIONAL SPECIFICATIONS ACCEPTED.

12842. Paul Leigh le Duc, for "Improvements in the construction of and in connections between axles or shafts and wheels, or other apparatus rotating around said axles or shafts, applicable to conveyances, machinery, revolving ventilators, or other apparatus." September 5, 1888.

13040. Hugh McKibbin, for "A novel arrangement of window-frames or sashes and the fasteners therefor." September 10, 1888.

13654. Comyn Ching, for "An improved chimney-breast ventilator." September 21, 1888.

13720. Samuel Alfred Varley, for "Improvements in the construction of lightning-conductors for the protection of buildings." September 22, 1888.

14327. Alexander Hutchison, for "Improvements in the construction of baths." October 5, 1888.

14491. William Sayer, for "Improvements in apparatus for making bricks, tiles, and similar articles from plastic clay and the like." October 9, 1888.

14539. Thomas Stephenson, for "Certain improvements in earthenware tiles." October 10, 1888.

14595. William Jarvis, for "Chimney tops." October 11, 1888.

14734. Bridgman Russell, for "An improved air-inlet ventilator." October 13, 1888.

14786. James Broadhurst, for "An improved oven or kiln for firing pottery or other articles." October 15, 1888.

14806. Archibald Duff, of the firm of Archibald Duff & Son, for "Improvements in and relating to drain-pipes." October 15, 1888.

15007. Joseph Arnold, for "Improved apparatus for disinfecting sewer gases." October 18, 1888.

15236. John Dewrance and Bonneval Edward Church, for "Improvements in the process of cementing asbestos." October 23, 1888.

## COMPLETE SPECIFICATIONS ACCEPTED.

Notice is hereby given, that all persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the date of the official *Journal*, give notice at the Patent Office in the prescribed form of such opposition.

15692. William Cooper and John Holdsworth, for "Combined hose, cart, fire-escape, and portable scaffolding." November 16, 1888.

16963. Arthur Klidge, for "Improvements in apparatus for opening and closing fanlights, skylights, and casements, and for retaining them in any desired position." December 9, 1887.

17542. Henry Sutcliffe, of the firm of Wright Sutcliffe & Son, for "Improvements in machines for the manufacture of water-closet basins, syphon and other bent pipes or stench traps in earthenware." December 21, 1887.

252. William Robert Green, for "Improvements in hydraulic lifts." January 6, 1888.

444. Joseph Hall, for "Improvements in firebrick register grate backs." January 11, 1888.

3856. Thomas William James and Henry James Brookes, for "Improvements in window sashes." March 13, 1888.

14029. Harold Berry, for "Dry earth and other closets." September 29, 1888.

14354. Harry Smith Edwards, James Harry Edwards, and George Straker Falck Edwards, for "Improved process of manufacturing cowls and apparatus therefor." October 5, 1888.

## PATENTS SEALED, NOVEMBER 9, 1888.

14460. Philip John Davies, for "Improvements in sink cones and stink traps, and casting them with lead." October 24, 1887.

14639. Henry John Alexander, for "Improved arrangement of ventilator for shafts, pipes, roofs, and the like." October 27, 1887.

14734. Samuel Carnaby, for "Improvements in apparatus or appliances for turning, opening, or closing Venetian window-blinds, ventilators, well-balanced windows, and other objects of a like nature." October 29, 1887.

683. William Charles Adolphus Holzapfel, for "An anti-corrosive composition for the protection of the inside of iron and steel vessels, bridges, piers, and other structures which may be exposed to the action of the atmosphere or water." January 16, 1888.

10035. Richard Wade Boyd, for "An improved ventilating and air-heating stove." July 10, 1888.

10527. Alfred Julius Boulton, for "Improvements in machines for lifting or delivering bricks or other articles." July 20, 1888.

# THE "THOMAS" LAMP.

Lighting Power with  
ordinary London Sixteen-  
Candle Gas, from tests  
taken by Professor Wm.  
Foster, M.A., L.R.C.S.

No.			
10.	11·4	Candle-power per foot.	
11.	12·5	"	"
12.	12·5	"	"

These Lamps are made in three  
sizes, Nos. 10, 11, 12.

These Lamps can be obtained through Gasfitters, Ironmongers and  
Merchants. Foreign Orders through Merchants only.

The advantages of this Patent  
over other existing Lamps  
are:—

Small consumption of Gas  
with great Illuminating power.

No possibility of the Burner  
corroding or getting out of  
order, as is the case with other  
generative gas lamps.

The Lamp can be fitted by  
any gasfitter. No fine per-  
forated metal, gauze, or other  
obstructions are used in this  
Patent, as in other lamps which  
are liable to become choked  
through imperfect combustion,  
rendering the lamps smoky and  
useless.

FOR FURTHER PARTICULARS, APPLY TO

**Ridsdale's Railway Lamp & Lighting Company, Ltd.,**  
**55 & 56 MINORIES, LONDON, E.C.**

# The Architect.

## THE WEEK.

THERE is fear that in the war between Government departments the competition for the new Opéra Comique of Paris will not be allowed. An official has prepared a design, and, as usual, a Minister is to be found to declare that it cannot be surpassed. The architects who hold Government diplomas have sent a memorial to the Minister of Public Instruction, who is the champion of the official's design. They say that, as the rebuilding of the theatre is a national work to be carried out by the Government, it is desirable that French artists be called on to co-operate in that work. It is argued that a competition is necessary, in order to display the new ideas upon the subject of the construction of theatres which are in the minds of architects, and which may lead to a transformation of the plan of those buildings. The memorialists, therefore, for the sake of art and in the interest of the public, solicit the Minister to use his influence in order that the project for competition shall not be set aside. Will M. LOCKROY be moved by the prayer of the memorialists? He may adopt the official plan because he fears that any other would probably lead to more expense than is desirable. M. LOCKROY cannot forget that the Opéra does not pay, and that its demolition was recently proposed. His ambition may be to create a more profitable building.

STRANGERS and children find subjects for admiration in the booths which from time to time appear in the streets of Continental cities and towns, but the inhabitants of the neighbourhood are not so well satisfied. In some places the boisterous music of the shows is not allowed in the day, but night can be made hideous by drums and trombones. People might bear with the revel on general holidays, but to be pestered by a crowd of idlers at busy times would overcome a philosopher. One of the artists' quarters of Paris now suffers from a renewal of a calamity known as the *fête foraine* of Montmartre. It spreads over the outer boulevard and into the adjoining streets, where there are painters' studios. There is not only noise, but a risk of an outbreak of fever, as the invaders care little for sanitation. The authorities appear too infirm to forbid the *fête*. A vigilance committee has therefore been formed, for the purpose of discovering some means to save the quarter next year. Among the members are M. GÉRÔME, the painter; M. ALEXIS BOUVIER, the novelist; M. BUSNACH, the dramatist; M. E. VIOLLET-LE-DUC, of the Historic Monuments Commission; and many other artists, writers, and savants.

ONE hundred and fifty designs for the diploma of the Paris International Exhibition are now before the jury who have to select the few which are to lead to the second competition. The Eiffel Tower is introduced in the majority of the designs as the most distinguishing feature of the Exhibition and the best suited to accompany the types of Labour, Peace, Truth, and the rest. Some artists have evidently set more value on the Exhibition as a memorial of the Revolution than as a field for the competition of all nations in works of peace. It is not impossible that a commission for the diploma will have to be given to some artist of eminence. BAUDRY's design served its purpose, yet it was not obtained by a competition.

SHERIFF COWAN delivered a righteous judgment in Paisley on Tuesday, when a church committee was made to pay money for plans. It appears that Mr. JAMES HAMILTON, a Glasgow architect, set out the site for a new church at Cardonald, and afterwards he prepared sketches for the building. The committee subsequently obtained plans in competition. Mr. HAMILTON applied for payment for his services as a surveyor, making no charge for the sketches, but the committee would not pay. Then an action was taken, when the committee pleaded non-employment. The Sheriff decided in favour of Mr. HAMILTON, and awarded him 36*l.* 1*s.* 4*d.*, with costs, for his work in preparing the

ground plans and pegging off the site for the church up to the time it had been agreed to have competitive plans. The Sheriff said that Mr. HAMILTON was an architect of some standing, and the presumption was all in his favour that it was not to be expected that a professional man was to give his labour and time for nothing.

MR. H. D. APPLETON read a paper on the "Affiliation of Architectural Students' Societies" before the Birmingham Architectural Association on Tuesday. The desirability of a strong bond of union between the students of architecture throughout the country was advocated, and it was urged that the union could be best accomplished by the aid of the students' societies of the United Kingdom. It was considered probable that such an amalgamation would result in interchanges of opinions and experience as would be calculated to make the students more proficient in their profession. With the Architectural Association as the bond of union there is a chance that the affiliation would be advantageous to many students.

THE South Kensington Handbooks are not to be devoted to art. Already two have appeared on "Adulteration of Foods" and on "Water." Another is now obtainable, which treats of "Marine Engines and Boilers," and is intended to supply, in conjunction with the collection of models relating to marine engineering at South Kensington Museum, a continuous account of the progress and development of the marine engine and boiler from the date of its first practical introduction, just a century ago, down to the present time. The handbook is written by Mr. G. G. V. HOLMES, the secretary of the Institution of Naval Architects, and is amply illustrated. It will be useful to students of mechanical engineering.

THE organ which blocks the north transept of the church of Stratford-on-Avon is to be removed, one portion to a position over the tower arch and facing the nave, where it will be supported by an ornamental gallery, and the remainder to be placed behind a carved screen below, near where the pulpit now stands. The cost of the work will be about 2,000*l.* The removal is to be commenced without delay, in order that the organ may be available for Easter.

THE Parliamentary notices are given of an application for an Act which will authorise the taking of the property in the parish of St. Margaret and the close of the collegiate church of St. Peter, Westminster, "for the purpose of opening out a view of Westminster Abbey, the chapter-house, and other buildings, and to appropriate a portion of the site so cleared for the erection of a monumental chapel in connection with Westminster Abbey," and in improving the approaches to the abbey and other property. The lands and houses proposed to be taken are "all the lands, houses, buildings, streets, roads, and premises within the area bounded on the east by Old Palace Yard and Abingdon Street, on the south by College Gardens, on the west by Dean Street, and on the north by Poet's Corner and Westminster Abbey." Parliament will also be asked to sanction the application of the whole or some part of the moneys raised or to be raised under the "Act to further continue and appropriate the London Coal and Wine Duties," or under any other Act or Acts; and to enable the London County Council, the Westminster District Board of Works, the Dean and Chapter of Westminster, the Government, the Ecclesiastical Commissioners, and any other body, trustees, &c., under disability to apply their funds to the objects of the intended Act; "and, if need be, the Act will authorise the levying of rates and assessments and the borrowing of money on mortgage, or by such other means as shall be sanctioned by Parliament." The proposed Act will or may provide that the chapel and any lands acquired under the powers to be sought for shall vest in the Dean and Chapter, the First Commissioner of Works, or in such other person or persons as the Act shall direct. Its powers and provisions will be carried into effect by commissioners or trustees, or by such other body or persons as Parliament shall determine.

## JOHN SELL COTMAN.

IT sometimes happens that a foreign critic is better able to anticipate the judgment of posterity upon English works. Being free from local or temporary prejudices, he is likely to be more impartial than the artists' countrymen, who may be biassed by enthusiasm or are indifferent through fear of self-reproach. When, therefore, we find M. CHESNEAU telling Frenchmen that JOHN SELL COTMAN, for his his tender and imaginative interpretation of Nature, should be set above many painters who had gained more renown—"JOHN SELL COTMAN que sa tendre et imaginative interprétation de la nature place au-dessus de beaucoup de peintres pour qui la renommée a été plus partielle"—we may believe that the painter's fame is not likely to decline hereafter. COTMAN would not be the first artist who was neglected during his life and idolised when dead. The exhibition of a collection of his drawings in the rooms of the Burlington Fine Arts Club is a token of the reputation which his works have gained in the course of a few years.

Little is known by most people about COTMAN, and hence it is often supposed that he worked at Norwich in the last century. But he died as late as 1842, in London, when he was in his sixtieth year. We may allow the eighteenth century all the credit that arises from his birth and early training, but as an artist he belongs to the present century. Happily there is as much grace and quietness about his works as if he were free from all influence of the feverishness and competition which characterised the greater part of the time since COTMAN lived in England.

What must strike every one who sees COTMAN's drawings in the Burlington Fine Arts Club or elsewhere is the general absence of features and effects which might be considered as baits to allure patrons. He painted as if for his own enjoyment, and did not hesitate about doing a great many things of which people would disapprove (such as painting the sea with brownish waves), as they were departures from what was commonly seen in galleries. Yet he was always poor, and although the sale of a drawing at any time would be of more importance to him than to the majority of his contemporaries, he never sacrificed his ideal. COTMAN, on the contrary, was ready to sacrifice most things for the sake of art. He was the son of a shopkeeper in Norwich, and if he had kept to silks and laces he might have prospered. There was, however, a spirit of rebellion everywhere in those days, and young COTMAN fled from Norwich to seek fame and fortune as an artist in London. Like so many with the same sort of ambition, he attracted the attention of the benevolent Dr. MONRO, who used to invite young artists to his country house in Bushey and pay them for sketching. COTMAN soon made his mark. In 1800 six of his drawings were to be seen in the Royal Academy, and in the same year he gained the palette of the Society of Arts. The titles of his drawings suggest that he sketched in Wales, Shropshire, Yorkshire, Lincolnshire, as well as nearer London. In a letter to DAWSON TURNER, the antiquary, dated November 30, 1805, COTMAN says:—"My chief study has been colouring from Nature, many of which [drawings] are close copies of that fickle Dame, consequently valuable on that account"—a statement which reveals his desire to be truthful. A letter to the same correspondent in the following year shows him settled in his native city. "In consequence of advice from several of my friends in Norwich," he writes, "I have taken a house in Wymer Street for the purpose of opening a school for drawing and design. It will give me the opportunity of turning myself about during my stay, and studying painting, which of late I have done but little, having been engaged in other things." At that time there was a Society of Artists in Norwich, and to the Exhibition of 1807 COTMAN sent twenty works. They were not all landscapes, as among them were six portraits and a sketch after VANDYKE, which suggests an attempt in a new field. In 1808 he was elected a member, and in the Exhibition of that year he was represented by sixty-seven works! There were figure subjects, portraits, and two "historical designs," besides the landscapes. It is also evident that COTMAN was trying his hand in oil-paintings, and we may note that he described himself as a "portrait-painter."

He was married in 1809, being then twenty-seven, and, to meet his increased expenses, he devised a plan of utilis-

ing his unsold drawings, which will be suggested by a copy of his advertisement:—

## A CIRCULATING COLLECTION OF DRAWINGS.

J. S. COTMAN

Has opened to the Public, on the plan of a Circulating Library, a COLLECTION OF SIX HUNDRED DRAWINGS, consisting of Landscapes, Compositions on Design and Figures, Coloured Sketches from Nature, Sketches in Claro Oscuro, and his original Pencil Sketches from the Saxon, Norman, and Gothic Architecture, chiefly from the counties of Yorkshire, Lincolnshire, Essex, and Norfolk.

Quarterly Subscription Ticket, One Guinea. J. S. Cotman will attend the delivery of the drawings to the subscribers, that he may facilitate their copying of them by his instructions.

Days of delivery, Mondays and Thursdays, between the hours of twelve and two.

In the Exhibitions at Norwich he used to mark certain drawings with an asterisk in the catalogue in order to denote that they belonged to his "circulating portfolios." COTMAN afterwards endeavoured to popularise his drawings by bringing out a series of etchings from them. For the first volume he obtained 212 subscribers, partly through the influence of his friend DAWSON TURNER, who lived in Yarmouth. In 1812 he removed to Southtown, where he taught drawing, but at the same time he kept up his connection with Norwich. The local artists recognised his merits by electing him president of the local society which had been founded by Old CROME and his pupils in 1805. Besides his work as a painter and a teacher, COTMAN brought out several books or collections of plates, such as "The Architectural Antiquities of Norfolk," "Norman and Gothic Architecture," "Antiquities of St. Mary's Chapel at Stourbridge," "Sepulchral Brasses in Norfolk," and especially "The Architectural Antiquities of Normandy," which was prepared in conjunction with DAWSON TURNER. He continued to exhibit in Norwich, and, as he was elected an Associate of the Society of Painters in Water-Colours in 1825, his work was also seen in London.

With all his efforts, the patronage he obtained was insufficient to enable him to live in comfort. COTMAN was naturally a sensitive man, and his disappointments gave him much pain. It is evident that in 1826 he was in terror about the fate of himself and his family, for his income was no more than 200*l.* a year. DAWSON TURNER, being apprehensive that the artist would go mad if he brooded over his misfortune, endeavoured to cheer him, and wrote a letter which is a model of friendliness and good sense. He advised COTMAN to give up his style of work, as it evidently was not satisfactory to the public. "The public," he said, "is a body that cannot be forced; some extraordinary geniuses may have succeeded in guiding it, but they are few, and the great part of those who have made the experiment have failed. Such as have to live by it must be content to follow its taste." The advice is a testimony to the originality of COTMAN's style, which the public of that time could not appreciate. The artist endeavoured to shake off his grief and set to work with new vigour, but purchasers continued to keep aloof from him. Three years afterwards, that is, in 1829, we find him writing to a clergyman:—"My views in life are so completely blasted, that I sink under the repeated and constant exertion of body and mind. Every effort has been tried, even without the hope of success; hence that loss of spirits amounting almost to despair. My eldest son, who is following the same miserable profession with myself, feels the same hopelessness; and his powers, once so promising, are evidently paralysed, and his health and spirits are gone. My amiable and deserving wife bears her part with fortitude. But the worm is there. My children cannot but feel the contagion. As a husband and father, bound by every tie human and divine to cherish and protect them, I leave you to suppose how impossible it must be for me to feel one joy divided from them. I watch them, and they me narrowly; and I see enough to make me broken-hearted." Yet at the time when COTMAN was suffering so much, he was obliged to take part as a steward in conversaziones which were got up in Norwich! Then, as now, it was necessary that amusement should be found for amateurs, whose interest in art rarely takes any other form.

Norwich was afforded the spectacle of a brave man undergoing misfortunes until 1834, when, partly through the help of MALLARD TURNER, the Professorship of Drawing in King's College, London, was offered to COTMAN. He

gladly accepted the appointment, but it was necessary to obtain money, and accordingly his furniture, books, pictures, drawings, armour, and in fact all the things which an artist finds a pleasure in having round him were sold. The highest price obtained for one of his oil-pictures was 5*l.* 5*s.*

COTMAN's residence in London was No. 42 Hunter Street, Brunswick Square, and the house should be marked by one of the tablets of the Society of Arts. He had passed his fiftieth year, and, from his position, might hope to lead a life that was more free from care. From his experience as a drawing-master he was well able to teach in the King's College classes, and the authorities of the College were considerate towards him. When he found the work onerous they appointed his son as assistant. His time was not entirely occupied with his duties in the College, and he was able to paint and etch. COTMAN was happy for a time. It is satisfactory to know that the Institute of Architects recognised his enthusiasm for ancient work by electing him as an honorary member. His "*Liber Studiorum*," a collection of forty-eight etchings, appeared in 1838. Soon afterwards his health began to decline, but he continued to work until the beginning of 1842. His death was ascribed to "natural decay," but it must have been owing partly to a recurrence of the old depression, which made him indifferent about all things. The doctor said that COTMAN was not suffering from any disorder, and that his depression was the consequence of not taking sufficient nourishment to gain strength. His daughter said that he "always expressed himself as though he hoped it would be the last time he should have to take anything." He was buried in the St. John's Wood Cemetery.

COTMAN's reputation will rest on his landscapes, taking that word as comprising drawings of the sea and buildings. Whatever the subject, it is treated with refinement. He was a close and loving observer of nature, and his sketches never fail to give the character of a scene. What, for instance, can be simpler than the drawing of Twickenham, of which the elements are a few trees obscuring the greater part of a house, with a couple of boats and a few figures? But somehow the drawing is more suggestive of Thames scenery, as seen along that part of the river, than larger works with much detail. He was one of the men who were able to appreciate the beauty of trees, and he is never happier than in subjects in which he could also introduce a lake or river to reflect the depths of their shadows. COTMAN was brought up in a flat country, but his early visits to Wales and Westmoreland impressed him with the grandeur of mountain scenery, and he always drew it with vigour. He was not much of a sailor, and probably would hardly venture to imitate TURNER, and be lashed to a mast in order that he might study waves. But as far as it was possible to be acquainted with the sea by watching it from the coast, COTMAN succeeded. The plate we publish this week reveals something of the power of waves. It may serve also to suggest COTMAN's power in representing clouds when winds are blowing. He is no less vigorous in depicting clouds that are not storm-tossed, and it may be said that, if judged by his atmospheric effects alone, COTMAN would be considered as having the powers of an interpreter of nature. COTMAN was one of the greatest of English architectural draughtsmen, and, as became an artist who in his early days was familiar with the Mediæval buildings of Norwich, he cared only for Gothic forms, and he was equally successful in representing what was found in France and Belgium. His architectural drawings, like his landscapes, are free from mannerisms; indeed, there are so few repetitions of that kind in his works, that some excuse may be offered for the authorities of public galleries when they introduced works as genuine which never came under COTMAN's eyes. Every subject seemed to suggest some new mode of treatment to him, and on that account it is most difficult to define COTMAN's characteristics as a painter.

There are three collectors who are fortunate in possessing many of COTMAN's water-colour drawings and drawings in black and white. They are Mr. BULWER, Q.C., Mr. COLMAN, M.P., and Mr. JAMES REEVE, and they have liberally contributed to the Exhibition in the Burlington Art Club. Mr. REEVE is not only a collector of drawings, but he has garnered every letter of COTMAN's or scrap relating to him, and his house in Norwich is a treasury of works of the Norwich School, and of information upon the artists.

## THE ARCHITECTURAL ASSOCIATION.

THE third ordinary meeting of the Association was held on Friday evening, Mr. H. D. Appleton, president, in the chair.

Mr. C. H. Brodie announced the formation of a social club, under the title of the Architectural Association Lyric Club, with Mr. H. D. Appleton as president, and Mr. Julian and Mr. Miller as vice-presidents. Two meetings will be held monthly, and the first of the series of smoking-concerts will take place at Anderton's Hotel, Fleet Street, on Thursday evening, December 6, at 8 P.M.

Mr. A. T. WALMISLEY, C.E., read a paper.

### Theory of Arched Structures.

Mr. Walmisley said that arches might be theoretically divided into classes:—(1) Treating of arches constructed of blocks of stone or brickwork, termed "*voussoir arches*"; and (2) treating of structures which are continuous partly or throughout, and which are termed for distinction "*elastic arches*," and that in a short paper it would be impossible to endeavour to exhaust the whole subject of arch construction. His remarks were therefore confined to those arches which are made up of cemented blocks, as the elastic arch belongs more to the province of civil engineering, whereas the *voussoir* arch plays an important part in nearly all structures designed by an architect. The laws which govern the stability of arches are the same for arches of any shape or form, whether applied to a bridge, vault, dome, or to any other arched structure. With this assumption it will be immaterial what form of arch the author illustrates to enable him to elucidate the theory, as any other form of arch can be treated in a similar manner. As a basis, it is usual to assume that each bed-joint in an arch-ring acts as a hinge about which the *voussoirs* are free to turn, and no allowance is therefore made for the adhesion of the mortar in the joints, so that to obtain stability the arch should be in equilibrium throughout.

There are many reasons why the adhesion of the mortar should not be considered: first, that in some cases mortar between the *voussoirs* has been left out altogether, and sheet lead substituted; secondly, that the mortar or cement, although generally good, may, through carelessness, be inferior in some of the bed-joints; thirdly, that an accumulation of dust, and neglect to saturate the surface of the material with water, may effectually prevent proper adhesion; and fourthly, vibration of the centres may be produced by the deposit of material, or movement may be caused by the varied positions of the loads as the work advances up the haunches.

In arches there are three different causes of failure:—(1) The arch may not be in equilibrium, and may collapse by altering its form. (2) The stones may be crushed. (3) The *voussoirs* may slide on their bed-joints.

The curve of equilibrium being an imaginary line representing the centre of pressure throughout the arch (supposing that the material were strong enough to resist crushing), the whole of the arch-ring might be removed except that portion immediately around the curve, and the arch would still remain perfectly stable. The curve of equilibrium changes its form for every alteration of load, except when all the weights are altered in the same ratio, in which case the load can be augmented or diminished, and the same curve maintained.

One of the conditions usually adopted with regard to the curve of equilibrium is that it should everywhere be within the middle third of the arch-ring—that is to say, if we divide the depth of the arch into three equal parts, forming concentric rings, the curve should everywhere be contained in the middle ring. This appears at first sight to be rather an arbitrary condition, but can be easily explained.

It is a well-known fact that all bodies are elastic, so that they will be extended or compressed according to the nature of the stress put upon them, and as we cannot have a tensile stress in masonry or brickwork without taking the mortar or cement into account, we must so distribute our pressures that no tensile stress will be set up. It therefore becomes a question how far the line of pressure may deviate from the neutral axis of the arch without a tensile stress being produced.

No doubt it has frequently been observed that if a plank of wood floating on water is loaded at one end, the loaded end will sink below the surface, while the unloaded end will rise above the surface until equilibrium is obtained, or, in other words, until the centre of buoyancy of the plank is coincident with what we may term the centre of effort of the water. The rise and fall of the ends of the plank relative to the water surface depend upon the position or amount of the weight placed upon it, and it will be found that the bottom of the plank at the higher end will just be level with the surface when the centre of gravity of the united weight of the plank and imposed load is one-sixth of the length of the plank from its centre.

This same law can be applied to masonry, for, the stones

being elastic, the compression of its particles will be in proportion to the weight supported; and when the centre of pressure is removed one-sixth of the length of the bed-joint from the centre, the edge of the stone furthest from the load will be relieved from pressure and become just on the verge of tension, which is a parallel case with the bottom surface of the plank at the furthest end being just level with the water.

When the curve of equilibrium or curve of pressure is anywhere within one-sixth of the length of the bed-joint from the neutral axis of the arch upon either side, it will be in the middle third, and no tension will be produced. As the curve of equilibrium approaches the edges of the arch-ring, tension will be produced, which will gradually increase until the curve passes outside the arch-ring, causing it to collapse, but practically the arch would collapse much sooner from the crushing of the material. Where the curve rises above the extrados of the voussoirs the arch would sink, and where the curve passes below the soffit the arch would rise.

An infinite number of curves of equilibrium can be drawn for the same loading, depending upon the rise given to the curve. The selection of the true curve generally requires some preliminary consideration, and may be determined on the basis of Moseley's principle of least resistance. The late Professor Rankine, in his "Applied Mechanics" (p. 215, article 196), thus states this principle:—"If the forces which balance each other in or upon a given body or structure be distinguished into two systems, called respectively 'active' and 'passive,' which stand to each other in the relation of cause and effect, then will the passive forces be the least which are capable of balancing the active forces consistently with the physical condition of the body or structure."

Now it is clear from this statement that the best curve to select is that which produces the least horizontal thrust. If a rope is stretched between two points so that the deflection is one-fourth of the span, and a similar rope is stretched in the same manner so that its deflection is half the span, it will be evident that the rope which has the least deflection, or which is stretched the tightest, will have the greatest horizontal stress, and it will be found that the horizontal stress varies in an inverse proportion to the deflection of the rope, so that the rope with half the deflection will have twice the horizontal stress of the other. Any rope, whatever the span, must theoretically have some deflection, even when unloaded, such deflection being due to its own weight. These conditions will be exactly the same for an arch, and will determine the position of the curve according to Moseley's principle—that is to say, the curve to be selected is that with the greatest rise and least span. As the middle third has already been fixed for the limit of the curve, it is obvious that the greatest rise given to the curve must be the outside limit of the middle third, and the least span the inside limit of the middle third.

In selecting the curve, it may be found that a curve which touches the middle third at the crown and springing will be outside the limit at some other point, and we may be able to bring it everywhere within the limit by slightly moving the crown and springing further inside the limit. In that case the curve, which falls everywhere within the limit, and which approaches nearest to the limit both at the crown and the springing, will be the curve to be selected.

To approximately determine the depth of the arch-ring at the crown, we can apply empirical formulæ founded by Rankine on the dimensions of good existing work.\*

They are as follows:—

Depth of keystone for a single arch in feet

$$= \sqrt{(12 \times \text{radius at crown})}.$$

Depth of keystone for an arch of a series in feet

$$= \sqrt{(17 \times \text{radius at crown})}.$$

The depth of an arch-ring does not depend upon the crushing strength of the material so much as upon the curve of equilibrium, which usually requires wide limits to provide for the necessary stability, and thus gives an area many times greater than is required to resist direct crushing—in practice the proportion has varied between 3 and 70, but the above formulæ by Rankine are based upon examples varying from 20 to 40.

Having approximately designed an arch, the curve of equilibrium can be drawn; but should the required conditions not be satisfied, the design will require modification, either by increasing the depth of the arch-ring, altering the rise, or altering the loads on the arch.

Mr. Walmisley then described how the curve of equilibrium was to be ascertained, as well as the solution of other problems in the construction of arches.

A vote of thanks was proposed by Mr. Lovegrove, seconded by Mr. Percy Hunter, and supported by Messrs. Collard, Beale, Fleming, Randolph, Lanchester, and passed by acclamation.

\* Rankine's *Civil Engineering* (Tenth Edition), Art. 290.

## THE AMERICAN ARCHITECTURAL MUSEUM.

THROUGH the generosity of an admirer of architecture New York will be endowed with a collection of casts of architecture. The subjoined report of the acquisitions in Europe by Mr. P. L. le Brun was read at the last convention of the American Institute of Architects. M. Chipiez, of Paris, the Comandatore Lanciani, of Rome, and Signor Giacomo Boni, of Venice, who aided the representative of the Willard Museum, were elected honorary fellows of the Institute:—

I have at last the honour to report to you that the installation of the Willard Architectural Collection in the main hall of the older portion of the Metropolitan Museum of Art is a matter of the immediate future, and only awaits the transfer of the objects lately exhibited there to their spacious new quarters in the enlarged museum.

The overcrowded condition of that institution for years past necessitated the postponement of the selecting and purchasing of the casts until provision was assured for their proper disposition and display. This enforced delay has, however, been of advantage to the fund placed at your disposal by the terms of the bequest, in the accumulation of four years' interest on the money devised. It has also permitted a more deliberate maturing of the work of selection.

The construction of the museum additions having apparently progressed last autumn sufficiently to warrant the purchasing of casts, your agent made his second trip to Europe, under your direction, for this purpose. Of the casts he then secured, the larger portion, or two hundred and fourteen cases, have arrived—leaving about eighty cases yet to come.

These boxes remain still unopened in the cellars of the museum, owing to the lack of space required for properly distributing and sorting their contents and putting together larger objects, which are mostly shipped in many parts, requiring a careful readjustment. And, as it is the intention of the museum authorities to reopen their collections to the public with the inauguration of their new extension, about the middle of December next, it will be impossible within that limited time to mount and prepare the Willard casts for exhibition. Much as this is to be regretted, it seems to have been unavoidable.

Since my last report the museum has added the west court—formerly devoted to the modern sculpture—to the uses of the Willard collection. This, and the placing of the principal entrance to the architectural court in the centre of the south side of the main room, have brought about a few unimportant shiftings of the arrangement outlined in that report, but its main features will remain the same, and the collection will be distributed likewise with a view to its extension northward, when the additions on that side are built—as will be inevitably required in the future.

Within the limits of this communication it will be unnecessary to allude specifically to any but some of the more prominent objects thus far purchased. In the scheme of the collection, typical models of entire buildings, made to a sufficiently large scale to permit of the accurate reproduction of detail, were assigned an important position. They are to form central crowning illustrations of the peculiar features of each important style, around which are to be grouped castings of detail, photographs, and works of reference.

A number of estimates were obtained from specialists, and contracts were made with a skilled sculptor of Paris for the production (as a commencement) of models of the Parthenon and of the cathedral of Paris, made to the uniform scale of one-twentieth full size.

They are well advanced, and, from photographs lately received of the portions already finished, promise to be very successful. In these models all the applied sculptures and carving are to be faithfully reproduced. Of Notre Dame Cathedral the exterior only will be shown, but of the Parthenon both the exterior and interior will be equally finished.

The architectural fidelity of these models may be estimated when it is stated that they are being made under the direct supervision of that distinguished French architect, Monsieur Charles Chipiez, who stands among the first of living authorities on architectural archaeology and history. This gentleman, with a generosity and fraternally artistic feeling that cannot be too highly appreciated, placed his services, on my application, at the disposition of the Willard Commission, and has supplied the sculptor with the drawings necessary to elucidate doubtful points in the construction of the Parthenon, as to which temple he has made extended special and original researches in connection with his work (in collaboration with Monsieur Perrot) in the forthcoming volume of their "Histoire de l'art dans l'Antiquité." His solution of the disputed points as to the manner of admitting the light to the interior, and of the external and internal polychromy of the building, will prove most interesting and valuable. And we may confidently share his expressed hope, that the Willard model of the Parthenon "will give of that superb edifice, which is so capital for instruction, an exact and complete idea, and that it will produce a certain impression on the public." To

heighten the realistic effect of the work, in addition to the reproduction of the Phidian statue of Athene Parthenos, the temple will contain a number of portable votive offerings and other artistic treasures, lists of which have been handed down to us.

The educational value of such an exhibit may be estimated when it is pictured surrounded by casts of the various architectural members of the building, the large pedestal of the model hung with restorations in tint and black and white, and photographic views, the reference library near at hand, with the standard works of Michaelis, Bötticher, and Penrose and others. And in a contiguous court (provided by the munificence of Mr. Marquand) a complete collection of casts of every known fragment of sculpture of this noblest edifice, friezes, metopes, and pediments. Could the study of its subtle æsthetic beauties be possibly better facilitated?

As to the magnificent model of the cathedral of Notre Dame, its execution will be facilitated greatly by the sculptor's access to the numerous drawings and studies of Viollet-le-Duc—made at the time of the restoration of this building—drawings which the kindness of the diocesan architect has placed at his disposition. All the sculptures, in the round and in relief, and the carving, will be rendered with as strict accuracy as the scale admits, and the photographs of the lowest section of the façade, with its rich, deeply recessed triple portals and the gallery of kings above, when compared with photographs taken directly from the building, show a remarkable fidelity to the original, not only in the general feeling, but in the minutest details of the sculpture.

As to the "bits"—among the larger pieces are a full-sized reproduction or cast of the Erechtheion Portico of the Caryatides; a model of the Choragic monument of Lysicrates, one-tenth full size; one complete bay of the Cloister of St. John Lateran, with the mosaics coloured as in the original; the pulpit front of Sant' Ambrogio, at Milan; the celebrated choir-screen of St. Michael's, at Hildesheim; the interesting carved wooden doorways of Aal and Flaa, Norway; the pulpit of Siena Cathedral; the Shrine of St. Sebaldu, Nuremberg; the doorway of the large hall in the Palazzo Vecchio, Florence; the tabernacle of Sta Maria in Trastevere; Monument of Count Bougival, at Breda; Jean Goujon's doorway from St. Maclou, Rouen; a model of the façade of the Knochenhauer Amsthaus (called the finest carved wooden building in Germany), made in finest style at one-tenth scale, and coloured as in the original.

Numerous smaller bits have been also secured to the number of about 950. But the work of selecting and purchasing may be said to be only fairly begun. The casts already bought represent but a portion—the bony framework, as it were—of what will eventually form the Willard collection, whose formation will be necessarily the work of time. The completing of the series of models alone will take several years.

The commencement which this report outlines should, however, prove a sturdy start in a most important undertaking, and should wake up architects and artisans and the architecture-loving public of New York to a realising sense of the duties which the inauguration of such a collection imposes—the duty, profit, and pleasure of study; the duty and privilege of patronising and enlarging its scope. For, to carry out fully the ambitious programme of its initiator and public-spirited testator, the means yet unexpended will, from present indications, be exhausted before the Willard Collection acquires such organic completeness and rounded fulness as will make of it truly an historical epitome of art.

#### SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.

AT the last monthly meeting of the Sheffield Society of Architects and Surveyors, a paper was read by Mr. E. J. Tarver, F.S.A., F.R.I.B.A., on "A Proposed Improvement in Theatre Planning."

It was remarked that fatal disasters occurred chiefly in passages and long staircases, which, being enclosed, afforded no expansion for the struggling column of human beings hemmed in between their walls. Thus the pressure became concentrated upon the foremost, if any hitch should occur even in an orderly exit, as at the Sunderland Theatre. He found these passages needlessly introduced and these staircases needlessly long in all existing theatres; for instance, the occupants of the front row of the gallery have usually to make an ascent of about 10 feet up to a back passage, and a corresponding descent of 10 feet down an enclosed staircase, bringing them to the precise level from which they started, after which they have to continue their descent to the street level. He traced the system of back corridors to the old opera-houses, whose several tiers of private boxes could be approached in no other way. A dramatic theatre, with its many rows of seats in each tier or gallery, offered a perfectly distinct problem to be solved, and Mr. Tarver said his method was to abolish back corridors as

entrances above the street level, and to enter from near the front in lowest row, thus leaving a much shortened descent to be completed in the enclosed staircases. He took special pains to guard against danger in rushing down the gallery. In working out this plan he duly provided for those who might have to escape from the back or highest levels, ample exits as to external stairs and landings, which gave a special character to the street front of his design.

Mr. C. J. Innocent said the paper had been eminently useful for architects and those concerned with theatres. The common sense and simple arrangements throughout the plan showed it had been well thought out. The site was of an ordinary and everyday character.

Mr. W. C. Fenton, building inspector, observed that having gone through many theatres in London and elsewhere of late, he considered Mr. Tarver's idea successful and practical. It had interested him much, as being the best plan of a theatre he had seen, providing the largest accommodation on a given area.

Mr. Cartledge pointed out the inconvenience of having the entrance to the gallery near the dress-circle entrance. People going to the gallery were in the habit of crowding round the door, and thus obstructing the people who wished to go into the house. To his idea the manager's office in the new plan seemed rather far from the street level.

Mr. Bramley directed attention to several features of the proposed new system of theatre building. It seemed to him that the pit was considerably below the elevation of the ground, and he would like to know if the descent from the exits to the door was not as dangerous as coming down a staircase. The difficulty was that in a time of panic the appliances, however ingenious, did not work. The Sheffield Theatre was arranged on short square flights of staircases, which were always square at the turns. The gallery staircase was supposed to be able to hold all the gallery could contain.

Mr. Tarver, in replying, answered various questions raised during the discussion. He said he had had the opportunity, through the kindness of Mr. Phipps, of seeing the new Shaftesbury theatre, which had external balconies. These, though of no great size, were sufficient, Mr. Phipps thought, to give the people confidence. The panic soon subsided if the people could get out of the building. He (Mr. Tarver) was not quite satisfied, and thought it would be better if the people could get down into the street. He was extremely pleased to find that no practical objection had been taken to his scheme in an assembly of gentlemen practically and professionally familiar with the subject.

#### LEICESTER AND LEICESTERSHIRE SOCIETY OF ARCHITECTS.

A LARGE meeting of members of this Society and their friends was held last week at the Medway Street Board School, Leicester, when Mr. R. Phené Spiers, F.S.A., delivered a lecture on the "Structural Origin of Some Forms of Mohammedan Architecture," illustrated by drawings on the black-board, and by an admirable collection of drawings and photographs. A vote of thanks, proposed by Mr. Jackson, seconded by Mr. Paget, and endorsed by the chairman, Mr. Tait, was carried by acclamation.

#### BUILDING IN GLASGOW.

THE opening meeting for the session of the Architectural Section of the Glasgow Philosophical Society was held on Monday night. Mr. James Thomson, the president, occupied the chair, and delivered an address, his subject being "A Review of Work done during the past Year." At the outset he referred to the losses the profession had recently sustained through death. After alluding briefly to the subjects of the registration of plumbers, the subway and Central Railway schemes, cross-river traffic, and the importance of improved dwellings for the working classes, he said that the recent great fire in Buchanan Street had had the effect of drawing public attention to the dangers that attend the mode of constructing large warehouses, and had drawn from the Lord Dean of Guild various remarks regarding it. He did not altogether agree with these remarks and statements, because he knew that the buildings in Buchanan Street destroyed by the late fire were erected in conformity with plans submitted to the Dean of Guild Court. If the plans were not properly drawn out they should not have been passed, and the work should not have been sanctioned, either at the beginning or the end of it. The two most important buildings which were sacrificed by the fire were erected within fourteen years, and were subject at all times to examination by the inspectors appointed by the Dean of Guild Court, so that if there were defects, which he dared say there

might be, these should have been seen and objected to at the time of building before the erections were ultimately passed by the Court as finished property. They all knew how architects got the blame of all defective construction, but in this case the whole blame could not rest with them. Speaking of the Exhibition, he said that the buildings and the numerous features of peculiar beauty all around them formed one of the finest pictures one could see anywhere. He did not think there had been any other voice than that of the most unqualified praise for the genius of the man who had conjured up and superintended the erection of the buildings, and who had crowned his life's work with this completed design, which, if produced alone, without another building, would have shown genius enough for one architect's life. Now they had to mourn his loss. It seemed cruel that a man should be snatched away just in the midst of work and honour. All that would soon remain of the great Exhibition would be the memory of James Sellars.

On the motion of Mr. Gildard, a cordial vote of thanks to the President for his address was agreed to.

Mr. David Thomson moved that the President and Mr. Lindsay Miller, the secretary, be requested to prepare a minute expressive of deep regret at the loss sustained by the death of Mr. Sellars, appreciation of his services to the section, and sympathy with his widow and family in their bereavement.

Mr. T. L. Watson seconded the motion, which was adopted.

### TESSERÆ.

#### The Influence of Vitruvius.

EMILE BOUTMY.

DURING a long period people looked at Athens through Rome, and with an incredible assurance credited the Greeks with the remains of architecture which are still found in the Roman Forum. Following the example of the great artists of the Renaissance, they imagined that in Vitruvius they possessed the Bible of Hellenic art, and all the forms which imagination drew from the sacred text were held to be authentic. It was believed that the Order of the temple of Hercules at Cora, or the Orders of Palladio, were as completely typical as the columns raised by Ictinus, and Mnésicles Calli-crates or Libon. If those great men could have visited Paris, it was imagined they would be surprised at nothing in the Madeleine or the Bourse except the scale of the buildings, and would have recognised in them not only the general dispositions of a Greek temple, but the special forms of each member, and, above all, the intelligence in disposition, the sentiment of harmony and proportion, and the fine taste which imparts tone and character to a style. A glance at the remains in Greece itself, by a few travellers, was sufficient to dispel the illusion. By a single authentic example it was demonstrated that in the great divisions of the composition, the proportions and the profiles, a Greek monument was without any resemblance to the buildings that are strewn over the surface of Latium. It was then found that Roman art, when compared with Greek art, was like the translations of Dacier, which, although said to be noble and generous, had been allowed to disfigure Homer for many years. It was soon found that the Roman Orders were not even a direct translation, that they were not derived from monumental styles of Greece during the age of Pericles, but from buildings in Eastern cities, which had been Hellenised by Alexander: in Pergamus, Cyzique, Antioch, Rhodes, and Alexandria rather than from Athens, the origination of the Greco-Latin must be sought. Finally, the discovery was made that Vitruvius, whose opinions were accepted in the blindest faith, knew no more of the architecture of Oriental Greece than was to be derived from books, and the prince of architects assumed his rightful position, that of a compiler from Alexandrian theorists. It was no longer astonishing to find him asserting that the ancients never employed the Doric Order in their temples, although the Parthenon happens to be Doric; or that temples should be so disposed as to allow the statue to look westward, although those found in Greece proper have all an eastern aspect, save one having its axis from south to north, and other absurdities. Evidently Vitruvius rarely quitted his library, and his studies were confined to the text of Hermogenus or other architects who had lived subsequent to the age of Alexander. In order to understand Greek art in its finest period, it is requisite to set aside so maladroit an interpreter, and to study such works as time and men have spared to us.

#### The Theatre of Pompey, Rome.

R. BURGESS.

This theatre reached its greatest splendour in the time of Nero. Two vanquished chiefs, who came from the north of Germany to render submission to the Emperor, were taken to Pompey's theatre in order that they might see the greatness of the people. It contained, according to Pliny, 40,000 spectators; and when Tiridates, king of Armenia, came to Rome, Nero caused the whole to be gilded, to show off the magnificence of

the Romans to the vanquished Asiatic. It passed through a succession of events until Theodorus commissioned Symmachus to rebuild it; but not long after it shared the fate of the rest of the splendid edifices of Rome, and finally came into possession of the Ursini family, who occupied that quarter of the city in the wars of the Middle Ages. In the fifteenth century an inscription, found with the name of Pompey, directed the antiquary to find out its site. Another indication of the place where this theatre stood was given in the finding of the famous statue which is now in the Palazzo Spada. That statue was found under the partition wall of a house, and lying across in such a way as to give two proprietors of the house a claim to the treasure: not able to agree about dividing the spoil, they came to the conclusion of cutting Pompey in two, and each man taking his own half. The matter having reached the ears of Cardinal Capodifezzo, he hastened to Pope Julius III. to inform him of the judgment that had been pronounced upon the statue. The astonished Pope despatched a messenger with all haste, and sent 500 scudi to be divided between the litigants, instead of Pompey. Flaminio Vacca, who relates this anecdote, says the statue was found near the Palazzo della Cancelleria, in the Vicolo dei Scutari. The statue did not stand in the theatre, but in the curia which Pompey built as an appendage to it, and the belief still obtains that it is the statue at the feet of which Cæsar fell. Being thus directed to the site of this famous building, we find ourselves in the immediate neighbourhood of the church of St. Andrea della Valle. From near that church to the Palazzo Pio the site is marked by a gradual rising of the ground, but no vestiges meet the eye. In order to see the remains of Pompey's theatre, we enter the courtyard of the Palazzo Pio, and descending into the vaults upon which the Palazzo is built, we find ourselves, at the depth of 40 Roman palms, among the foundation arches. These have been originally hollowed out of the natural rock, and they are pointed at the angles with large blocks of peperine stone. One of the cunei or sections of the cavea belonging to the lowest tier may be perfectly traced; and after ascending to the courtyard again, and upon entering the stables, we see a second storey of arches for supporting the seats, the construction of which is remarkable for its solidity; and it would not be difficult to trace, among the modern buildings and in the cellars of the Palazzo, at least one-half, perhaps two-thirds, of the whole cavea. Vitruvius cites the Porticus Pompeiana as an example of what a portico should be when attached to a theatre for the convenience of the actors, or for the people to take shelter in in case of rain. We know, from Martial, that Pompey's portico had a hundred columns. Eusebius calls it, in consequence, "Hecatonstylon." This celebrated portico was painted by artists of renown—Antiphilus, Pausias, and Nicias—the subjects being suited to the atmosphere which Ovid's lovers breathed.

#### Sea Water and Iron.

W. REID.

Almost everyone has observed pebbles adhering to old anchors which have long lain under the sea. Engineers who have had to remove piles from sea walls or harbours have also noticed similar effects, for the iron shoes at the points of the piles have generally a mass of pebbles strongly encrusted around them. Even in what we call fresh water (but which on analysis always is found to contain salts in solution) this effect in a smaller degree is observed. Having had occasion to reset part of what are called breakwaters at Portsmouth, which are covered every tide by the sea, I was there enabled in many instances to notice the effects here alluded to. Some of the examples afforded beautiful specimens, and of several varieties, of the carbonates of iron of perfect forms. When examined with a powerful lens very delicate needle crystals were often distinctly visible; these last which I observed were white. Those resembling carbonates of iron varied from black to brown, and to bright yellow: some of the browns were of a very rich colour. These specimens were not found at Portsmouth only; at Hurst Castle planks of considerable dimensions, which the gales had broken from the groins, were found firmly encrusted with silicious pebbles. It was not at first easy to discover from what cause the pebbles adhered to the wood, but on sawing a plank longitudinally it was found to have been driven full of iron scupper-nails. The flat beads of these nails were almost touching each other; the heads had nearly disappeared, and in their place a black shiny crystalline matter had been formed, which firmly united a layer of pebbles to the plank. The opinion I formed on this was that voltaic action takes place between the metallic iron and silicious pebbles when immersed in sea water. If this be the case, we can scarcely doubt but that something of the same nature will occur between iron and other stones when similarly placed. Part of the breakwaters at Portsmouth were set with very thin sheet-iron, between blocks of Swanage stone, as an experiment. In a month afterwards sand and small pebbles were found firmly fixed between the iron and the stone, and black crystalline matter, such as had been found at Hurst Castle, appeared forming, and the experi-

ment, as far as it has been observed, seemed satisfactory. After thus setting the breakwater with stones, alternating with plates of sheet-iron, I observed that Mr. Cross had previously pursued studies somewhat similar, and he was satisfied that iron, when in contact with silex in a fluid medium, exhibits electric phenomena. An observation to this effect will be found in Mr. Leiths's work on electricity. The subject of the formation of crystals by voltaic electricity, which is one of great interest, is now making considerable progress, and the object of this paper is to endeavour to show that the pursuit of the study may be practically useful when applied to hydraulic works, and that it well deserves to be ascertained whether plates of thin iron, alternating with stones, and placed under the sea, will not be found to form solid rock, with crystalline veins. Mixtures of iron filings, sand, and gravel, let down to the bottom of the sea through tubes, might perhaps consolidate and form a stable foundation for lighthouses and other works, for which it is very difficult to form a base. Those parts of the Portsmouth breakwater set with the thin sheet-iron will be found between the Saluting Battery and the Spur Redoubt, and are visible on close inspection. The experiment has been varied, somewhat in the manner above alluded to, by the authority of the Admiralty. Unserviceable iron water-tanks from ships of war have been filled with gravel, mixed with iron turnings and a small quantity of lime, in the construction of a groin opposite to Haslar Hospital. The greater part of this groin will be covered by the tides, and thus a good opportunity will there be afforded of observing the effects of iron in contact with pebbles when immersed in salt water.

#### Art and Society.

DAVID SCOTT.

Art—we use the term in its inclusive signification—stands connected with the movements of society in a double relation. It influences, and is influenced by, them. It gives impulse to and at the same time follows, those movements—the one from its ultimate adherence in, and value in relation to, the intimation or awakened operation (particularly in its highest or most worthy departments, but in all, to a certain extent, even by its specific nature) of those elements of the mind which are most humanising or most essentially establish the distinction of humanity in man; the other by frequently deriving its forms and clothing from those changes which pass over, or rather in themselves constitute, the visible enudation or detailed features of his mental being as displayed in society; changes, the “equal step” of which are often as much beyond the reach of scrutiny and the control of established systems of laws and elaborated institutions, which, instead of directing, usually intimate the departure of the passing spirit, and cripple often its footprints, as the passage of an epidemic, a year of plenty, or of dearth. In its origin, art is antecedent to the varied modes of life, while in the manner of its announcement of sentiment it is frequently sequent to them. The effects which it produces are the result of its progression from sources which are pervading, and not liable to be dried up; it serves as a perpetual record, intimation, and renewal of the youth and strength of the mind, keeping alive the verdure of the soul. But opposed to this—its virtue or distinctive value—by the forms of society by which it is operated upon, it is not unfrequently thrown into ranges of expression which sufficiently exhibit both the impress of these forms, worthless as they are at times, and its liability to be brought into connection with subordinate and fluctuating purposes in all their variety. Two diverse positions are thus occupied by art and established in respect to it: the one primary and holding a direct connection with the mind; the other still necessarily exemplifying the manifestation of particular portions of the mental constitution, but in accordance with their combinations displayed in other it may be more subordinate or more extended features of society.

#### Mediæval Love of Colour.

L. VITET.

Painting being more perishable than sculpture, it was inevitable that the remains of works by Mediæval artists should be very few and imperfect in condition. I am speaking, of course, of monumental painting on stone or fresco, for what is known as painting nowadays, that is, the painting of pictures, was not contemporaneous with the architecture and the sculpture of the Middle Ages: it appeared at a later time and followed a road apart. The precursor for it is to be found in an art that is now lost—the illumination of manuscripts. It is solely upon the parchment of the missals and the coloured psalters of the cloisters that we must seek what in the twelfth, thirteenth, and fourteenth centuries corresponded most nearly with our easel pictures. There is much in that form of Mediæval art which makes it most interesting for the student, for we find an imagination that was rich and bold displayed in the fantastic borders of the illuminations, design that is sometimes piquant, drawing that faithfully represents the usages and costumes of the time, and colours that are excellent as regards preparation and laying on; but, with all these qualities, we

cannot regard the illuminations as representing the painter's work of the Middle Ages. For what relationship can be found between these masterpieces of patience, these microscopic drawings, and the great monuments of architecture that seem to be the work of giants rather than ordinary men? It should not be forgotten that in Mediæval days society consisted of two worlds, that were separated and differed one from the other. One was all study and patience, the second all action and courage. In the cloisters the inhabitants spoke a dead language, in the castles and fields the language was an idiom young and vigorous. While the painters in the monasteries amused themselves with fixing minute quantities of gold and colours upon leaves of vellum, the wall-painters, the veritable painters of that age, who were the rivals of the architects, the sculptors, and the carvers, proceeded more boldly, and spread their gold and colours in arabesques and figures upon the walls and vaults of churches and châteaux. We cannot comprehend the art of the Middle Ages, and must form an imperfect idea of the grand creations of the architecture and sculpture of that time if we do not picture to ourselves the buildings and the figures covered with gold and colours. Of all the importations from the East, not one was accepted with so general a favour as the taste and the necessity for colour. The people wished to see everything coloured, even light itself, and the sun's rays henceforth penetrated into habitations through yellow, red, and blue. Stained glass could have had no other origin: it was the natural consequence of the new system of decoration, and of the passion for colour that was derived from the East. In the seventh and eighth centuries, in the beginning of the ninth, and in the eleventh century that passion made some conquests, but they were partial, and did not long endure. After the return of the Crusaders colour triumphed, and during three centuries France was amorous of it, as Greece had been at all times.

#### Thirteenth-century Glass.

G. E. STREET.

Glass in windows ought to be transparent and brilliant, and it can only be used properly in separate pieces leaded together, each piece of colour being on a distinct piece of glass; it must, therefore, be a mosaic, and cannot attempt to vie with the free work of the painter's brush on walls or canvas. Its most marked qualities must be brilliancy of colour, transparency of effect, and distinctness of outline. In these qualities no other vehicle can rival it, and true wisdom consists in using it most for those purposes for which it is most fitted. The attempt to imitate wall-paintings which has been often made of late is, from the nature of the material, sure to fail, and will in course of time fail still more signally than it has when decay sets in, as it will in such complicated work much sooner than in a mosaic of properly coloured material, such as the early painters used. The one is of necessity perishable and not thoroughly transparent, the other may be said to be truly indestructible, and is perfectly transparent. The mosaic mode is therefore that which seems to be the true and proper one, and the early painters may be said to have been fortunate in knowing of no other. Their glass is generally either extremely rich in gorgeous colour, or of the simplest kind, painted with delicate trailing patterns of foliage on a white ground. In the former the tints used were extremely brilliant, and the whole detail of the richest possible description. The artists regarded their work rather as intended to conduce to the general tone of colour in the building, than to teach people in the way in which a picture on a wall might teach them. It is true that their windows in churches are often full from one end to the other of figures or subjects painted in a most elaborate way. It would have been impossible, indeed, to dispense with “subject” windows; but, on the other hand, they were evidently designed much more with a view to gaining the greatest amount of general effect, than to producing the prettiest or most intelligible picture in one spot. If you were to examine most of the best of the thirteenth-century glass, you would see that the whole of the design and the mode of drawing are made entirely subservient to the requirements of the material. The foliage enrichments are drawn with great power, untiring patience, and marvellous intricacy; the figures are rude, as might be expected at the hands of men who had seldom if ever thought of studying from the life, but they were always drawn with an honest desire to make them tell their story, and with a vigour and distinctness of action which cannot be too much praised. If then, after looking at old glass, you were to examine the modern imitations of it, you would find them startlingly deficient in almost all the good qualities of the former. The material used is thin and poor in tint; the drawing, in trying to be correct, has become tame and insipid, and the arrangement of colour shows generally but little appreciation of the right mode of producing effect. So that here, as in almost all other matters, thirteenth-century art, tried by the test of critical examination, comes out from the ordeal unscathed, whilst the work of our own days appears to be scarcely art, but rather a habit of thoughtless compliance with what is supposed to be the taste of the day.

## NOTES AND COMMENTS.

THE illustration we publish to-day from COTMAN'S drawing is the first of a series that will suggest his skill in all the branches of work which he attempted. At one time copies were made in lithography from COTMAN'S drawings for the Government art schools, but they were only translations. The plates we propose to publish, being produced by photography, come far nearer to the originals, and will reveal his whole manner of working. We trust they will serve in making COTMAN'S name a household word in England, the Colonies, and America.

THE selection of M. CHAPU as the sculptor for the statue of HONORÉ DE BALZAC, although approved by Frenchmen, has caused bitter disappointment to M. MARQUET DE VASSELLOT, who for twenty years has had one fixed idea, viz., that he was destined to make a statue of the novelist. The committee having charge of the subscriptions avoided a competition, and sought a sculptor by visiting the *ateliers* of a select number of sculptors, and discussing the subject with the owners. Finally, it was considered that the wisest course was to offer the commission to M. CHAPU. The decision dispelled all M. DE VASSELLOT'S dreams. He had prepared himself for the work by making four or five busts of BALZAC, he had made models of a memorial, and had so constantly studied the novels that he considered himself confident to create figures of at least three hundred of the characters. M. DE VASSELLOT would not be called a very successful sculptor, for he has obtained few medals, and, when an artist has formed a definite plan as he did, he is not likely to care about any other. For M. DE VASSELLOT believed that if he could make his mark by the monument of BALZAC, then the future was secure. The committee having failed, the sculptor has turned to his successful rival and has put the circumstances before him with an appeal to his generosity. To a man in M. CHAPU'S position, what is one monument more or less, while the victory means loss to M. DE VASSELLOT and misery to his family? In a case of the kind, what is to be done? If M. CHAPU gave up his commission, would the committee give it to the sculptor who was so eager to obtain it? Many claims might be set up, and the task of the committee would become oppressive. The narrative recalls the disappointment which was felt by BENJAMIN HAYDON under similar circumstances. All his life he was insisting on the duty of the State to give commissions for mural pictures, and he was dreaming of the time when he was to receive them. His joy was great when it was announced that the Houses of Parliament were to be adorned in that way. He took part in the competition, and the smallest prize was not awarded to him. M. DE VASSELLOT is, therefore, not the first artist who has been foiled in the ambition of his life.

THE collection of cartoons, designs in oil and water-colours, studies, models and photographs, which constituted the monumental art section of the Brussels Exhibition, should have been acquired for this country, where so little is known about the decoration of public buildings. The opportunity has vanished. The Belgians have secured the collection, and it will form the nucleus of a permanent museum of monumental art. There are many artists in Belgium who are skilful as decorators and in mural paintings, but it is felt that, with so important a branch of art, it is wise to be acquainted with the best works of Frenchmen, Germans, and Austrians. Having a Civil Service that is remunerated according to the value of the work done, Belgium is able to expend large sums of money in works of art. We are far richer in England, but as long as the official world absorbs so much money as it now does, we must suffer, and see most desirable works carried off by rivals.

It is reported that Professor KOUDAHON, the Russian archaeologist, has been fortunate in his explorations in the Chersonese. He is said to have found some fifty ex-

amples of Greek terra-cotta which belong to a period of about three centuries before the Christian era. They are considered to surpass in beauty the figures that were dug up at Kertch. There are statues of APOLLO, BACCHUS, and PAN, mythological groups, masks, heads, and medallions. It is supposed they were not imported from Greece, but were produced by Grecian artists who lived in that part of the Crimea.

MR. EWAN CHRISTIAN has offered the following suggestions to the School Board for London, but they are no less worthy of adoption as canons of administration by School Boards and building committees throughout the country:—  
(a) All questions in respect of quality and depth of foundations to be finally settled, and the work, if differing from the drawings, measured and agreed, and extras and omissions balanced, within one week after its completion up to the level of the ground damp-proof course. (b) That similarly all questions in respect of variations, extra works, and omissions on the carcass of the building above the level before mentioned, shall be settled immediately after the completion of the roofing in, and the building of the chimneys, and before any plastering whatever is executed. (c) That all questions as to the drainage shall be similarly examined into and settled, and the drains tested, before the trenches are filled in. (d) That in like manner all questions as to minor buildings and boundary fence walls shall be similarly adjusted and settled up to the fixed level of the damp-proof course. (e) That all fence walls uncovered by roofing, built between September 29 and March 25, shall be carried up wholly in cement mortar. (f) All pointing of joints to be finished as the work proceeds. (g) All building of gable and parapet walls and chimneys above the roof to be carried out in cement, and that in every case of a new building builders giving tenders shall be required to state the additional cost of building the whole of the work in cement under the conditions laid down in the specification. (h) No surface cut or rubbed brickwork to be used. All mouldings and strings, where introduced, to be of moulded bricks of the best and most durable quality, and all projecting joints filled in with cement. (i) Any cornices or string moulds requiring it to be covered with lead, and the use of zinc for that purpose to be finally abolished. (j) No ornamental work whatever of a perishable quality to be anywhere introduced into any of the school buildings erected by the Board.

COMPETITION often helps to produce good work, but in the case of archæology it cannot be imagined that much is gained by the rivalry of societies. Mr. JOHN HONEYMAN is therefore expressing an opinion which is held outside the societies, if not in them, when he says that "we have arrived at such a stage in several lines of research as to make some well-organised scheme of co-operation a necessity, if we would avoid wasting of energy and gain further substantial progress." If the various archæological societies will only count their gains during late years, they must admit they are not progressing. What is more curious is that people are taking less interest in archæology. Mr. HONEYMAN says there should be "an association of all the archæological societies in the country, so to organise the archæological work of the country as to turn it to the best possible account. The task ought properly to be undertaken by the Society of Antiquaries; but it is needless to expect that—the more's the pity. Failing the Society of Antiquaries, the British Archæological Association might perhaps take it up as their exclusive function, apart from their annual congress, which would go very well along with it." Better still would be the creation of a new association in which the various provincial societies could combine. Very little is done for archæology by dwellers in the metropolis; the Society of Antiquaries is degenerating more and more every year, and the British Archæological Association has lost its influence. It is to the provinces we must look for a revival of archæology, and any society that proposes to be useful must recognise that fact. Reunion of provincial societies would not be a difficult task, nor the agreement in a common course of action.

NO. 43.—ARCH. AUGUSTA, PERUGIA. [J. A. SLATER.]

NEW CHURCH OF ST. FRANCIS OF SALES, TOTTENHAM.

THIS church is about to be erected on a very fine site in the High Road, in front of the existing school-chapel. The walls are to be faced with coursed walling of hard stone, with Bath dressings, and the roofs covered with green slates. The spire, 140 feet high, will be constructed of timber and leaded. Bath stone will be used inside, excepting the clustered columns of the chancel, which are to be of marble. These latter will carry a groined timber roof as well as the arches springing from the same level. The nave will have a segmental timber vault, with moulded transverse ribs and cornice. The flooring is to be of wood blocks and marble mosaic. There will be sitting accommodation for about seven hundred persons. Messrs. J. & B. SINNOTT, of Liverpool, are the architects.

TWO HOUSES, BROMLEY PARK ESTATE, BROMLEY, KENT.

THESE sketches illustrate two houses just finished on the estate of Mr. S. CAWSTON. They are situated in an elevated and well-wooded position, commanding a view of Shortlands Valley. They are built of a sharp red brick, with Bath stone dressings and tiled roofs, the upper storeys being of half-timbered work, filled with cream-coloured rough cast; the pillars and doors being of oak. They were erected from the designs of Mr. WALTER A. WILLIAMS, architect, Bromley and London; the builder being Mr. A. J. ECCORDT, of Bromley.

## PROGRESS IN CONSTRUCTION.

IN the course of his presidential address before the Society of Architects at the Arts and Crafts Exhibition, Mr. Seth Smith spoke on this subject as follows:—

I will now glance at the past year's advances in construction, fittings, and such like branches of our work. To take building materials first. Pink terra-cotta, as hard and sound as the best buff, has been difficult to obtain until quite recently, but is now being made successfully. Manufacturers are also succeeding in getting all terra-cotta truer in shape and freer from cracks, and it is a far more reliable material to-day than it could be said to be hitherto. Architects are designing their work to avoid the large unwieldy blocks with which there was so much risk. This year has seen greatly increased demand for terra-cotta and also for facing bricks in terra-cotta clay; the latter are finding their way into several places where they were never used before, Ireland, Scotland and the south coast of England, and I am told that a very large consignment of red terra-cotta bricks has just gone off to Egypt.

Considerable progress has also been made during the last year in the production of glazed bricks that are soft and good in colour, and absolutely impervious to all atmospheric influences, the body of the colour and the glaze being made an essential part of the brick, so that neither colour nor surface will be affected by damp or frost, and it will sustain a severe crushing strain. I must mention also a rich brown-yellow terra-cotta in which the lines and arises can be made almost, if not quite, as true as stone; buildings in this material are to be seen in Piccadilly Circus, and it has also been selected for the New Métropole Hotel, at Brighton, on account of the warmth of its colour and its impervious character. I am also informed that in connection with some work for the Museum of Science and Art, at Dublin, great technical accuracy has been secured in carrying out some Lucca-della-Robbia faience work.

Marble as an internal wall decoration is being more largely

used every year; one has only to visit, among the latest buildings, the National Liberal and the Constitutional Clubs, the National Gallery, and the Gallery in which we meet to-night, to form an opinion as to its suitability for such purposes. In a few of the more recent important public works steel box girders are adopted of considerable span, carrying loads of enormous weight. Rolled joists and joist girders are also being made of steel, but not in very large quantities; iron is much cheaper and suits most purposes perhaps even better than steel. The steel used for constructional purposes is that termed "mild," and equal to an ultimate tensile stress of 30 tons per square inch. This result, when compared with the iron value of 4 or 5 tons per square inch, shows an immense advantage in favour of steel. The saving in money, however, is very little, if anything, as reliable steel is dearer than iron. The principal advantage lies in the fact that for carrying heavy weights steel girders may be made so much lighter than iron, and then a great saving in carriage, hoisting, and fixing is effected when the quantity is large; the same consideration also applies to the use of steel cylindrical columns and steel joists; but it must not be lost sight of that steel constructions are not likely to stand so well in cases of great heat. It is to be regretted that, notwithstanding several attempts by English firms to roll iron joists, they have been constantly beaten, both in quality and price, by the Belgian makers. English manufacturers who could supply iron joists at or a trifle below Belgian prices would confer a great benefit upon the country. The demand for steel joists has been better met in England, although at prices above iron. To ensure both the specified quality of iron and the proper construction, it is always best to have it tested on the site; the cost is comparatively small, and, as a rule, it is quite practicable.

Any such review as this would be inadequate which omitted to mention the admirable system of fireproof flooring now in the market, which, though not quite new, has been improved in various ways during the past year. I refer particularly to the pumice concrete flooring for bearings up to 20 feet. It consists, as you are aware, of rolled steel or iron joists spaced according to the loads to be carried, filled in between and entirely embedded in this pumice concrete with a uniformly flat soffit. This material is 25 per cent. lighter, much more sound and fireproof than ordinary concrete, and can be nailed to as easily and effectually as to wood.

Another great advantage of this system is that the iron joists are interlaced with strained trussed wires, about every 18 inches, which gives great homogeneity and toughness to the floor and prevents fracture by settlement. I am assured that no expansion or contraction takes place in such floors under any circumstances.

Where time is an important factor, pumice concrete slabs are laid dry and afterwards grouted in with cement. The well-known steel trough flooring is being more than ever used for larger spans, and various methods of fixing the wood floors above, and the ceilings beneath the steel channels, are novel and ingenious.

This fireproof construction has been used within the past year for roofs, no fillets or boarding having been necessary, but felt is laid on a floated surface and the lead rolls screwed to the concrete.

Unless one, or at any rate a thoroughly congenial mind directs at once the structure, its fittings and decoration, a really harmonious result cannot be expected. As to advance in the decorative world I will content myself with the quotation,

"Si monumentum requiris, circumspice."

Among fittings, stoves and chimneypieces deserve the first mention.

There is a strong disposition to make more use of the open recess and dog-grate in the reception-rooms. No doubt this arises from the artistic and varied treatment of which they are capable; they are not economical in fuel, or equal in heating power to other forms. If, however, the sides of the recess are splayed, the stove set close to back of recess, and the register is made as long as the opening and placed well back, the soffit of arch or lintel being rounded off to it, the result is generally satisfactory. I have found it very important, in order to ensure success, to allow the makers to fix their own fittings. For inexpensive buildings cast-iron chimneypieces are being more than ever used on account of their great cheapness and durability, while many firms are doing much to improve their design.

It pays well, when doing up old houses, to fix plain-coloured glazed tile-hearths and fenders throughout, both as a saving of labour, to say nothing of appearance and cleanliness.

We now come to the important subject of artificial lighting. The extension of the electric light must to a large extent depend on the successful formation of central electric lighting stations, as in this way electricity can be obtained by householders in the same way as gas, the company bringing their mains to the doors and supplying suitable meters to consumers of the current.

In America, central station work has of late increased enormously. In London, Sir Coutts Lindsay, otherwise the "London Electric Supply Co.," has hitherto been practically the only company supplying electricity from a centre; but another company, "The Metropolitan Electric Supply Co.," has recently been formed, with some of the most powerful financial men connected with submarine telegraphy as directors, whose intention it is to deal with the question of the supply of electricity thoroughly and efficiently. But, besides this, there have been several other smaller companies formed, such as the "Chelsea Electric Light Company," working under license in the Chelsea district. "The Kensington Court and Knightsbridge Electric Light Company," "The Cadogan Electric Light Company," and the "House to House Electric Light Company," who are putting up their first station in South Kensington.

The coming year will undoubtedly work a very great and important advance in the supply of electric light, as, I presume, these companies will by that time be in a position to supply large areas.

In many of the most important provincial cities and towns great stir has already been made, and various electrical lighting companies are projected. The change is made by the Board of Trade unit, viz.—1,000 watts—and in most cases the price is 7½d. to 8d. for such a unit; 7½d. per unit would work out at about a farthing per 8 candle-power lamp, and is somewhere equivalent to 4s. per cubic feet of gas. Various meters have already been devised for ascertaining the consumption.

With regard to how the lamps should be disposed for electric lighting, suspension lights at a suitable distance from the ground, with clusters of three or five lamps in each, appear to answer best; large clusters of lamps on an electrolier are wasteful. Single lights, on the other hand, leave a general effect of insufficient light.

The ceiling lighting is being altered at one of the largest London clubs, as it is found to be so wasteful of light. The incandescent lamps are at present retailed at from 4s. to 5s. each. I understand there is a possibility, should the Edison Swan Company lose their case in the Court of Appeal, that the price may be reduced to 1s. 6d. to 2s. per lamp.

I am often asked how will the development of electric lighting affect the great gas companies. It is difficult to prophesy. At present there is no appreciable falling off in the demand; and the announcement from the Gas Light and Coal Company within the last few days, that they are about to lower the price, will handicap electric lighting more than anything. Up to this time, where the electric light has been installed, it has generally necessitated the use of a powerful gas engine, which has consumed nearly as much gas in the production of electricity as would have illuminated the building, but the central station system will alter all this.

It must, however, never be lost sight of that, perfect as is the electric light for the purpose of illumination and as giving off less heat, it lacks the great power existing in a gas flame—properly controlled—to ventilate an apartment. I should, therefore, not be surprised if a combined use of gas for cooking, warming, and ventilating, and electric light were for this reason to become more general.

The Cromartie and the Wenham gas light are very economical consumers of gas, and if their flues are kept regularly swept and they are hung in clusters to obviate the shadow they otherwise throw upon the ceiling, they are very powerful and specially adapted for the dual purpose of light and ventilation. The clever Welsbach gas light is the most economical of all in point of consumption of gas, and being a Bunsen burner the combustion is as perfect as possible, and the injury to decorations, &c., consequently very small as compared with all others.

Electric lighting has revolutionised the old gaseliers and brackets, and well illustrates the effect of science on art. Great credit is due to the leading manufacturers for the development of beaten copper in the foliated parts; copper is too soft constructionally but harmonises beautifully with brass. One great principle in all artificial lighting is to have no naked burners, but to diffuse the light through ground glass or silk.

Wrought-iron, the beauty of which was suddenly appreciated seven or eight years ago, is daily improving in design, more especially under the hands of several excellent firms. Many architects are now having their door locks, handles, sash and casement fastenings, stays and bolts, &c., specially forged. Few details better repay the effort of designing them. The locks are being again fixed outside instead of inside the framing, and treated ornamentally, instead of destroying the rail tenon; and the lift-up latch, with a bolt only inside the door, is being used for bedrooms.

It is of course not always possible to afford carrying these features to the delightful point of varying each lock fitting, but it is quite legitimate to have a set made from our own design in malleable iron, so long as the moulds are destroyed and the pattern thus confined to one building. The great demand for wrought-iron has, a leading producer assures me, decreased the cost of production by exactly one-half in the last four years.

Nothing could be more beautiful or suitable than plain hammered iron in contact with unpolished oak, stonework, &c., and of course it can be painted to any extent, but something more refined is required where the surrounding surfaces are delicate and highly polished. One can in these cases coat the iron with nickel, platinum, silver, or gold, or polish its surface. Just now some beautiful work is being done by bronzing copper and brass to a deep blackish tone; this material possesses a sort of silvery green tone, and when enriched with silvered or gilded foliage, produces a most satisfactory effect. Polished iron can now be protected from rust for a long time and it is often extremely effective. Gilt iron toned down with stains is most beautiful.

#### GLASGOW ARCHÆOLOGICAL SOCIETY.

THE thirty-second annual general meeting of the Glasgow Archæological Society was held on Thursday in last week. Mr. John Honeyman, president, occupied the chair, and there was a large attendance of members.

Mr. Wm. George Black submitted the annual report of the Council, which referred to the interest which the Society had taken in the scheme for the exhibition of a collection of historical and archæological objects in the Bishop's Castle of the Exhibition, and the success with which the scheme had been carried through; and traced the proceedings of the British Archæological Association when holding its annual Congress in Glasgow. The number of members admitted during the year was twenty-seven, making the present membership eleven honorary and 248 ordinary members.

The report was adopted.

Mr. John Honeyman then delivered the introductory address, in the course of which he said:—The more we examine Glasgow Cathedral the more we must be struck with the fact that, as a field for fresh discovery, it seems to be inexhaustible. I never visit it as a student without finding something new, and never have I been more impressed with its marvellous variety and beauty of design, and the excellence of its structural details, than on the occasion of my last visit. The object of this visit was to search for old work—I mean twelfth-century work—at the west end of the crypt, to make sure that I had not overlooked anything of the sort. I found, as I expected, that the whole of the west wall is of the same age as the rest of the crypt, and we have absolutely nothing to indicate what the previous building was like, except the small transitional fragment at the south-west entrance and the position of the shrine of the patron saint. This subject—the early arrangement, or rather the origin of the peculiar arrangement of the choir and crypt—has been invested with quite a new interest by the very suggestive remarks of the Marquess of Bute at one of the meetings of the Congress. The idea of tracing the origin of arrangements in a thirteenth-century church here to Italian models is apt to be dismissed without much consideration by ecclesiologists. But that will not be so if the very peculiar circumstances of the case are taken into account. Let us glance at the state of matters immediately antecedent to the episcopate of Achaius. First of all we must remember that, at a time when Roman influence was distinctly visible in the early ecclesiastical buildings of England, Rome had positively no influence here. Then in the eleventh and twelfth centuries, when a change occurred in this respect, the architecture of England had developed into a truly national style; the plan and arrangement of church, as well as many details, had become distinctly English. We had then English-Norman and Transitional architecture, differing characteristically even from the architecture of France, with which it was most closely allied. Now, it was this English variety of Romanesque which was introduced into Scotland by Malcolm Canmore and his sainted queen. Wherever their influence was paramount there we find that churches were erected after the English model, and, no doubt, designed by Englishmen, for Margaret's recognised spiritual father and adviser was Bishop Lanfranc, of Canterbury, who aided her in her missionary enterprise, not only by his counsel, but by sending her earnest and trustworthy men, familiar with the customs and arts of the south. Hence, no doubt, the curious and interesting fact that even the chapels of that period which remain are good examples of English-Norman architecture. The arrangement of high altar immediately over the shrine of the patron saint is not uncommon in our early churches—as at Canterbury, Durham, Dunfermline, and elsewhere; but it is traceable directly to Rome at a much earlier period. The original church at Canterbury was no doubt founded on a Roman model, and we have already noticed the connection between Canterbury and Dunfermline. Of the second church—that built by Jocelin—we know almost as little as of the first. It was probably somewhat larger, and I think we may say certainly more substantial and costly. The approach to the crypt would be as at present. The east end would not be much beyond the shrine of St Kentigern, and the high altar would, as before, be over the

tomb. The most marked difference of arrangement in the present church is that the high altar is not immediately above the tomb. Bondington projected his church on so grand a scale that the end of his choir was a long way east from that of the older building, and the position of the high altar was necessarily changed. This subject is capable of further elucidation, and is deserving of it; meantime I would only further remark that if we grant the Italian origin of the general arrangement we are not required to admit that anything else about the building indicates foreign influence till we come down to near the close of the fifteenth century. The square termination of the choir is not French. The details of the crypt and choir are in no respect French; but you will find the identical details at Lincoln, Rievaulx, Furness, York, and English and Scottish works of the same period too numerous to mention—not copied from each other, observe, but executed simultaneously. The shortness of the transept has been referred to as indicating French influence, but, I think, erroneously. The transept is short for the good common-sense reason that owing to the way the floor space is cut up by the stairs to the crypt a longer transept would have been useless, and owing to the form of the ground it would have been costly, and the architect of our cathedral was much too clever a man to do what was at once costly and useless. Besides, it is not only as short as a French transept, but shorter, which should satisfy us of its strong individuality and its purely utilitarian origin. In French cathedrals where the transept does not project beyond the side aisles there are generally four. Again, the arrangement of the east end is quite original, and is a clever device to overcome the difficulties of the site. The space beyond the choir has hitherto been called (erroneously, no doubt) the lady chapel. Mr. Loftus Brock, at our meeting in the cathedral, suggested that it should rather be called the retro-choir. That would certainly be preferable, but still I can hardly think it strictly applicable. A lady chapel may, and sometimes is, with strict propriety termed a retro-choir—it is, in fact, a small choir behind the main choir; but here we have nothing whatever in the shape of a choir. It is not even a chapel, but a cluster of chapels—the outside aisle being divided into chapels as in the crypt below, and the inner aisle forming an ambulatory connecting the north and south side aisles. The termination of the choir is emphasised by the introduction of the centre pier, which may be said to carry the main arcading right round the east end; the only difference indeed between the end and the sides is that at the end there are two aisles instead of one, and the roof of these aisles being kept flat, there is no triforium, and the windows are therefore carried down to the string-course immediately above the main arcading. The arrangement is quite unusual, and fortunately it has come down to us unaltered, owing to the great difficulty of making any extension eastwards. It is rather curious that the doors to the vestry and the chapter-house, in the choir and crypt respectively, were not kept a bay further west, so as not to interfere with the use of the north-east bays as chapels.

I must express my sympathy with Dr. Burns in his desire to see our beautiful cathedral more appropriately arranged and furnished. I am quite sure that any movement with this object in view will have the hearty support of this Society. We are very specially interested here on the subject of the preservation of ancient buildings, because it is impossible to deny that our own cathedral suffers from the present mal-administration. I need hardly say that I do not blame the subordinate officials of the Board of Works. They are helpless in the matter, and the Department itself blames Parliament for not granting enough of funds; but they will never get enough of funds if they don't ask for them, and they will never ask for them unless they have a proper sense of the responsibility they incur when they neglect what is absolutely necessary for the safety of such a building as Glasgow Cathedral. For such a purpose Parliament would not grudge the necessary money. The citizens of Glasgow themselves would gladly provide it if the Government gave up its charge altogether. I do not say that this is desirable; but on principle it is clearly wrong that national burdens should be unequally distributed. The question is not, Do the people of Glasgow think the cathedral worth preserving? but, Do the people of the United Kingdom think it worth preserving? And if the answer to that question be in the affirmative, no plea of poverty will exonerate a Government Department from the consequences of a neglected duty. Here we have good cause to complain of neglect, and for anxiety, but I do not think that any immediate danger is to be apprehended from the defect recently pointed out by Mr. Loftus Brock. The inclination of the north walls of the nave is, in my opinion, a more serious matter, especially as no attempt has been made to construct the aisle roof in such a way as to give the clerestory the most effective support; but there is a still more dangerous settlement at the south-east corner of the choir. The attention of the First Commissioner of Works was called to this several years ago, when the rent which extends irregularly from top to bottom had opened ominously. It was then suggested that the foundation at that point should be examined and secured, and

the bend of the wall restored, and Dr. Cochran-Patrick and Dr. Cameron, who had an interview with the First Commissioner on the subject, were assured that it would receive immediate attention. It is hardly credible that all that was actually done was to plaster up the crack with cement. The most cursory examination by any professional man must have satisfied him that, except for the purposes of stopping a cold blast which found its way freely through the crevice, such treatment was absolutely useless; so that, in face of that fact, it must be held that the authorities deliberately chose to run the risk of the east gable of the cathedral coming down by the run, rather than spend the small sum necessary to insure its safety. The action of the Department in this case, I think, clearly points to the expediency of taking the charge of ancient monuments entirely out of its hands, and transferring it either to a body specially constituted for the purpose, and comprising local representatives, or to such existing bodies as the Board of Manufactures (whose chief fault is in its name), composed of men having local knowledge and a keen patriotic interest in the objects committed to their care. I need hardly say that the settlement at the east end of the cathedral continues. The crack has reopened, and another eighth of an inch at the level of the choir window-sills must now be added to the inclination of the east wall. The total width of the rent in the eastmost bay is  $7\frac{1}{4}$  inches, and this has from time to time been simply plastered up. It does not require an expert to understand how real and serious this danger is, and how greatly it is increased by delay. Every year that passes without the proper remedies being applied makes the task more difficult, and—as movement continues—prolonged neglect must certainly lead to sudden disaster. It is not the only part of the building which is being neglected, but it is the most important, and I allude to it as of itself a sufficient justification for demanding that the charge of such precious monuments shall be transferred to more sympathetic custodians. Before leaving this subject I must just in a word refer to other objectionable features in the present arrangement. It almost seems as if it would require an Act of Parliament to get the absurd placards removed from the building. The Board of Manufactures would make short work of them. Then there is the exclusion of the public two days in the week unless they pay for admission. Why should any British subject pay for admission to a national monument? Lastly, and worst of all, a visitor is not allowed to sketch in the building unless he has written permission from the Board of Works, and that can not be obtained in Glasgow! The necessary permission should in any case be obtainable within a quarter of an hour; but I must express my strong disapproval of the modern fashion of requiring such permits in our ancient buildings. It may be taken for granted, indeed it is morally certain, that those who wish to sketch are not likely to destroy, and the most that should be asked of them is that they should sign their names in a book kept in the building for the purpose.

A vote of thanks was accorded to Mr. Honeyman for his address.

#### THE ARCHÆOLOGY OF THE WALLACE SWORD.

THE sword which used to be in Dumbarton Castle, and which is supposed to have belonged to Sir William Wallace, has been removed to the National Wallace Monument at Stirling. The Rev. Dr. Rogers, of Edinburgh, who was influential in the transference, said:—

This sword is associated with a glorious history, for it was wielded by one who, in an age when principle succumbed to expediency, was pure and without reproach; who never yielded allegiance where it was not strictly due; and who resisted oppression to the death. Consequent on fractures which have been twice welded, the weapon has been reduced from its original length, but it was at first a noble blade, which, in respect of its possessor, was in the poet's words—

Fit for archangel to wield,  
Yet light in his terrible hand.

Borne by the patriot at the battle of Stirling Bridge, it signalled the commencement of a struggle which was not to terminate until the prostrate spirit of the nation had been revived, nor again to droop or decay till on the field of Bannockburn were repelled the hosts of the invader. When foully captured, as he slept at Robroyston, on the night of August 5, 1305, Wallace had this great blade resting by his pillow; and when he was hastened to London to meet his cruel death, it was borne to Dumbarton as the prize of its governor, the recreant Scotsman who had betrayed its possessor. At Dumbarton the sword has for six long centuries remained as a protest against treachery and injustice, and now, at the hands of Colonel Nightingale, as commander at Dumbarton and Stirling, it is to become a trophy in the patriot's monument. As governor of Dumbarton, Sir John Monteith received this sword in August 1305, and two hundred years

thereafter, namely, on December 8, 1505, the accounts of the Lord High Treasurer inform us that, at the command of James IV., the sum of twenty-six shillings, equal to about thirty pounds of our present money, was paid to an armourer for binding a riding sword and a rapier; also for the "binding of Wallace sword with cords of silk," and providing it with "ane new hilt and plomet," also a "new scabbard and new belt." And it will be remarked that while the rapier and the riding sword are named as being simply repaired, the Wallace sword is described as adorned with trappings of silk; also as having been provided with the specified additions of a new hilt and pommel, a new scabbard, and a new belt. Concerning the weapon we learn nothing further for 320 years; but a letter which, in October 1872, I received from the War Office, informs me that in the year 1825 the sword was sent for repair to the Tower, when the Duke of Wellington, as Master-General of the Ordnance, submitted it for examination to Dr. Meyrick. This gentleman, afterwards Sir Samuel Meyrick, was an authority as to ancient swords, but in estimating the age of the Dumbarton weapon he was guided by its mountings only. Judging from these, he concluded that the sword was not older than a sword in the British Museum connected with the Earldom of Chester, and belonging to the reign of Edward IV. That I may not misinterpret his sentiments, I quote from Sir Samuel's work on "Ancient Armour," in which, at vol. ii., p. 177, when referring to the reign of Edward IV., he writes:—"The two-handed sword, shown at Dumbarton Castle as that of Wallace, is of this period, as will be evident to any one who compares it with that of the Earldom of Chester in the British Museum." The Chester sword was afterwards examined by Mr. George Ormerod, of the Society of Antiquaries, who, in the fifth volume of "Vetusta Monumenta," shows that the weapon was the Sword of State which Edward V. had borne before him when, as Prince of Wales, he, in 1475, made a triumphal entry into Chester Castle. If, then, the Chester sword belongs to the year 1475, Sir Samuel Meyrick approximates nearly to the date of the mounting of the Wallace sword, which occurred just thirty years later. But the Wallace sword was, in 1505, an old blade, which required a new hilt and pommel, a new scabbard, and a new belt. And as the weapon was then so materially shattered, it seems reasonable to conclude that it was decidedly ancient; moreover, that before it was allowed to rest in the Dumbarton armoury, it had been subjected to much hard usage. And its being adorned with silk tassels, by the King's command, leaves us in no doubt as to its being held in special veneration; while in the register the weapon is described as "Wallas sword," no qualifying word of doubt being expressed as to its genuineness. And apart from the circumstance that by two separate weldings the blade has been shortened, it is otherwise a duplicate of the two-handed blade of Sir Richard Lundin, used at the battle of Stirling, now preserved at Drummond Castle. I compared the swords in 1861, when they were together under my charge. One blunder leads to another. Consequent upon Sir Samuel Meyrick's judgment pronounced in 1825, the mountings of 1505 were removed, and a common handle of the fifteenth century substituted. This information I obtained in the letter which, in 1872, I received from the War Office. But now that we have got possession of the sword, we shall be careful that the weapon with which the hero was wont to "mak great rowme" about him will be mounted in the fashion in which he nobly grasped it, and we shall retain it as no unimportant addition to the national regalia.

#### HEAVY BUILDINGS.\*

WHAT is a heavy building? It is certainly no new thing. The world is dotted with them so freely that, in abundance of human interests, they rival the works of nature. But architecture changes as time changes. Each age has its character which is recorded in its buildings more permanently than in anything else. The ambitious efforts of the eras of military conquest and the monumental expressions of those of religious enthusiasm are written clearly in the wrought stone of the old edifices which are our inheritance. And these are not undervalued. We still experience the same emotions and passions and express them, more or less ably, in the same materials. We still build towers and cathedrals and tombs, and all these might come in a general way under the title of this paper.

But there is now a new order of things, this is the epoch of industrial enterprises. Let us consider for a little time this newer work we are doing. We are not in the habit of looking far into the past for guidance in the scientific department of our labours however often we may grope there for artistic inspiration. And this is because most of what we do is new. The architects of ancient times have raised thousand of tons of marble in majestic beauty; that was their aim and object in building, and all else subordinated to it. We are called upon

to deal with equal or greater structures with certain additional demands of utility and economy which would have rendered the task impossible to the masters of olden times. The stately buildings of this class which tower over the streets of our modern cities are loaded with tier upon tier of spacious chambers; they are permeated with countless flues and ducts and wires, and made alive with machinery vibrating with enormous power. And with all this, the walls upon which they are upheld must be pierced with innumerable windows and doors, so that the light of day and swarms of busy workers or luxurious residents and their attendants may have free access even to the basements and cellars. These tiers of floors must often support enormous loads of merchandise or of machinery or of human beings, and, lastly, the structural materials must not be only incombustible, but as far as possible fireproof.

Under these conditions we find that our work is, in truth, of a new order of things, and in that new order ideas develop rapidly; the most daring conceptions of one generation become the commonplace thoughts of the next. Accumulated experience reduces to method all those theories which are found worthy of it by the tests of practice, and the quicker we can evolve these methods and formulate their rules the easier our progress and the freer our course to the next stage wherein new problems await us; therefore one of the tendencies brought about by the need for these heavy buildings is toward mutual assistance—a careful observation of what other things are doing.

There is undoubtedly too little attention given to the process which may be called the analysis of contemporary art. In the earnestness of individual work there is too much isolation and independence. The man who discovers says nothing of his thought, and each one of us explores and rediscovers the same truth; and indeed there is a harmful impression that the rule of originality should be interpreted to debar the adoption and repetition even of a good principle, so that what is done in this direction is to some extent disguised and apologised for. It was not thus that the old-time heroes in our craft worked. From the time of the Pyramids down to that of the Renaissance the schools were more evident than the individuals, and, whether by master or by pupil, the work shows subordination to accepted codes. From these undisputed principles individual labours toward perfection commenced at a stage higher than that at which many now terminate.

It was by this collective knowledge the Greeks carried refinement of detail to its height, and (to go from one extreme example to another), it is by the power of the same method, the acceptance and adoption of certain unoriginal but established types, that the designers and builders of the least educated class among us are enabled to erect fairly satisfactory structures of many storeys and complex arrangements, such as the cheaper flat and tenement buildings of New York City. We will not overlook the imperfections of these buildings, nor will we mention them as worthy of imitation, but they do teach the lesson of co-operation and collective experience which enables work to be done by men, not one of whom independently and originally would be competent to do it. The diversified character of buildings of the higher order may lessen the opportunity for this evolution of their design, but it does not preclude it. There is enough of it evident to show the need for more. Much has been said and written of late, especially in Europe, about a modern style of architecture. The nearest approach to it is without doubt shown in modern American business buildings, and if the best specimens by the acknowledged leaders in our art are compared it will be seen that sometimes unconsciously, even unwillingly, they follow more or less perfectly the same methods. Heavy buildings of this class promise to compel by their limitations a uniformity of design which almost amounts to a style. In order to discover the laws of this style, let us examine then practically the circumstances in which they originate. Scientific design proceeds upon past experience by continuing or adopting successful features and avoiding known faults. What then are the successes and the faults in recent heavy buildings? It is understood that fireproof buildings of many storeys are more particularly referred to.

Despite all that has been learned and written upon the subject the great difficulty of unequal settlement is the chief cause of faults. I speak of the settlement by compression of the soil upon which a building stands. It is a curious fact that much of the most valuable and densely covered building land in the world is notoriously bad. Many of the heaviest buildings stand on soft, yielding soil. The lower part of New York with quicksands, silt and mud, Boston with its districts of made ground where tidal water used to ebb and flow, Chicago with its lake shore alluvium and wet sand, all furnish examples of this. Among older sites Pisa whose leaning tower has puzzled so many diletanti into fanciful fiction, and Venice and Antwerp and London may be mentioned, the last including large areas of the blue clay of the Thames basin. The commercial origin of their prosperity accounts for it. Where the ships came the cities grew, and there the architects were set

\* A paper read at the Buffalo Convention of the American Institute of Architects, by Mr. R. W. Gibson.

to work. Sometimes other causes prevail; as, for example, at Albany, where the New York State Capitol stands upon a hill of clay, but this same clay when it lies with its natural stratification unbroken is in the writer's experience found to be a better soil than is generally supposed.

But let us not linger upon subjects already extensively discussed. These compressible soils, it is well known, must be built upon with equalised loads. The law may be accepted as established that each square foot of base of pier and wall must bear with an equal pressure in order to secure an equal settlement. But we may still look around us and see faults which this doctrine was to banish. This subject was chosen because of the discovery by the writer, in a series of examinations of modern buildings, of the fact that unequal settlements abound. And here are some of the reasons. We calculate the loads upon our girders, columns, walls, and piers, and we say, for example, column C in a ten-storey building has a base bearing three tons per superficial foot, and wall W X a base expanded to give the same pressure. Wall W X we will assume to be a side wall in a building not on a corner. The structure is finished and occupied, and the wall W X slowly and irresistibly takes its half-inch, or inch, or more of settlement, squeezing down the soft soil despite all preliminary ramming or other preparation. This we expected, but why are the floor levels disturbed, and why those little cracks in the front lintels and sills if all has settled together? It is somewhat disappointing to look about and see how many sills and lintels betray this fault of unequal settlement by a crack close to one end—just the bearing end broken off. Inside the building the columns in several cases appear to have lifted. It has been argued that the brick and mortar was compressed in its numerous joints, while the iron of necessity is not perceptibly changed. This is true, but not to the extent now in question. Let us look at our calculations again. The wall is all right—so many feet, so many tons; the columns, so many feet of iron, so many feet of floor, weighing perhaps 70 pounds per foot, so many feet of floor loads at 150 pounds per foot—here we have the error. We may say it is not an error, but anything is an error which produces bad results unexpectedly. The floor loads are not there. The masonwork is on the wall base in actual fact, but the load of 150 pounds per foot is on the floors only in theory, and the column foundation which we assume to support, say 300 tons, has actually only 180 tons. What wonder that there is trouble! And in the front, where the girder ends rest upon the front pier, as they usually should do, the same thing occurs in a lesser degree. There is a larger proportion of masonwork in the calculated load, and only one girder instead of two, but the difference here even amounts perhaps to 100 tons. What can be done? Custom based upon knowledge requires that each floor shall be equal to a safe load of 150 lbs. per foot. In New York City the law requires this for a fireproof office building, and further, that the columns shall be safely equal to the total of all the floors upon them at the same rate. This would seem to be unnecessary in many cases. In each floor an excessive strength is demanded to guard against contingencies, such as the movement of heavy safes or the possible use of some floors for storage, but on all the floors together a fair average is permissible, because the average is always naturally maintained by reason of the number and variety of the different storeys. The columns we may, however, accept in compliance with the law and customs; the excess is not harmful, but in the foundations we have seen that it is positively injurious. The laws, recognising the impossibility of the task, usually leave the arrangement of this part to be done according to circumstances, except that they stipulate a minimum, applicable to good soil, which does not approach the necessities of the cases under consideration.

The foundations of columns should be equalised with those of walls upon a basis of a liberal but not excessive average of floor loads, say 50 lbs. or 60 lbs. per foot besides the weight of the floor material. This could not possibly be surpassed in an office or apartment building; it is the weight of a crowded-seated audience on every floor at once; it is an allowance of ten or twelve tons of load in an office or apartment 22 feet by 18 feet; if some floors could possibly be loaded more heavily others would certainly carry less. Let us work according to these facts, and while we may still expect a few cracked ends of lintels the difficulty will assuredly be lessened. It is, therefore, evident that while excessive strength is a harmless precaution in the actual structure, yet a true calculation is necessary for foundation areas.

Next, let us give some further attention to the front. There is a natural set of dimensions, arising from limitations and requirements, in these buildings which leads us all for some time in similar paths. The storeys (excepting the first) are usually required about 11 or 12 feet high, the girders 15 or 16 feet apart, in order to use convenient spans of beams and floor arches, and the limits of the bearing of girders will be naturally 20 to 24 feet. If the building is so wide as to demand columns,

because first, the side walls and foundations, with few or no openings, are in themselves extremely heavy, while the front and rear walls with numerous windows are lighter; and secondly, because the homogeneous side wall is more adapted to receive the distributed floor beams, while the front and rear walls, already divided into piers and openings, are better fitted for fewer concentrated weights. The windows will be required about 4 or 5 feet wide, with piers of 3 or 4 feet between, or perhaps the openings rather less and the piers or walls more according to the purpose of the building. This agrees very well with our spacing of girders, except that two windows come to each division, and here we have the motive for the design of three-fourths of our modern heavy buildings. The two windows are combined, and the pier carrying the girder increased, while the other is lessened. The heavy construction of course compels openings to be placed in perpendicular lines, except in the uppermost storeys. So far so good; but now arises another difficulty which has been abundantly studied. The intermediate pier is often carried up from the same foundation (usually continuous under such a front) which carries the main piers. These latter with their enormous loads, perhaps 400 tons each, compress the soil as calculated, but the foundation laid continuous does not remain so. The part loaded goes down, the part under the windows remains where it was placed, and the intermediate columns, whose comparatively little weight rests upon it, do as it does. All the way up the front is slightly distorted, and lintels are cracked. When the writer first began these observations, the cracks in the lintels were rather puzzling. There seemed to be in many cases no apparent cause. The fact is it takes very little unevenness to produce a crack. The force is irresistible, and the lintel is a small stone. A good precaution is to give it only so much bearing as is necessary, so that there is less of the end held in the vice-like grip. With stone resting on stones 3 inches is enough, and many bands, sills, lintels, &c., have 8 or 9 inches running into the pier. If the building is thus more flexible, it will not show these movements at such a trifling stage. But let us go to the root of the evil. Shall we hold down that lighter portion of the continuous foundation and compel it to go all together? And if so, how? The inverted arch is the first thing likely to be called for. It is a doubtful aid for this purpose. If used it should be of ample rise, or rather drop, and a pointed or Gothic form would be best. In a wall with a good depth of masonry below it the arch is no doubt good. It does not take the whole load of its span, but down actually at the bottom next to the concrete an inverted arch must be loaded with about 2½ tons to the superficial foot of base. Think of this enormous load. Turn the arch the other way up and think of it. It is perhaps 6 feet wide, the base is perhaps 10 feet; that makes it loaded with 24 tons per foot of length if considered as a bridge. The thrust is enormous. Imagine the girder necessary to do this work. If it does not do this work it will not compress the soil, as it would demand of it. Suppose we lessened the load by reducing the width; practically this almost amounts to giving up the continuity of the base course. This will be sometimes a gain, especially if the piers are far apart. Or the great piers may have side footings which meet at the foot of the small ones, one the base course, those on the other faces being proportionately less. Then if the great piers are equalised the small ones will be carried down with them; but a flat inverted arch will do no more good than the slab of concrete or the base course of granite. Brickwork and concrete must be considered as possessing no transverse or beam strength under these loads. They will resist pressure, and will spread it, at an angle of about twenty-five degrees from the perpendicular, no more, and the batter of the offsets, or the chord of each half invert, should be at about this angle. There are granite bases to be seen whose offset equals their height, in which an apparent tilt upwards has resulted from the failure of the masonry to carry the pressure out at so great an angle.

But the true way to make our light intermediate piers go down with the heavy ones is to build them upon girders or arches resting upon the latter. Then, even if the great piers differ in settlement, the smaller will maintain their proper intermediate position. It has been assumed that a front entirely of masonry was in question. This undoubtedly is a higher grade of architecture than that in which iron is freely used. Sometimes we see the main piers of masonry carried up with the intermediate piers and other parts entirely of iron, each floor carrying its own tier. This is good in the main, but it misses many of the best opportunities for design, and is of necessity monotonous. Sometimes the iron features are grouped two or three storeys together under arches of masonry; this is better, the stone construction is more complete, and the iron subordinated to it. And other things being equal, the use of masonry throughout will undoubtedly produce the greatest dignity of effect. Now we have reached the point in the argument where æsthetic ideas are invited to take their place. Here are encountered the facts upon which it is submitted the modern style is founded. Yet the constructive and the artistic are, as they should be, so closely linked that we must not attempt to con-

sider them apart. We have traced the development of the achievement of an equal foundation, now for the superstructure. The superintendent of the New York Building Department once said (if the veracity of a New York reporter may be trusted), "that the commonest error in construction was that of making column and piers too big above and too small below." He referred no doubt to the class of designers before alluded to, whose skill is perceptible only when collected into a sort of joint stock of that commodity. But the same charge in a lesser degree could be made against some buildings of the first class. An intermediate column or pier supports the lintels and the sills of the next storey above, and then comes another similar column, and so on to the top. This is all very well for two or three storeys, because the smallest desirable column will be competent to that extent, and because the uniform size of windows suggests equal columns, but if six or eight tiers are so raised it becomes questionable and monotonous. The single girder, too, has to be made very strong to avoid perceptible deflection, as it is loaded in the centre. To meet this objection another improvement is developed. The two or three storeys for which the superimposed columns are proper are so designed, and then a new girder is introduced with, perhaps for variety's sake, one storey entirely open immediately under it, and the intermediate columns again above. In this we get the numerous tiers of floors and windows reduced to groups. Now, we all know how certain critics of the last generation have protested against the grouping of storeys, as in the Palladian style, condemning it as untruthful and unconstructive; yet there has been an instinctive reluctance to abandon it, and we may be assured that any persistent instinctive feeling of this kind is based upon some reason, although that reason may not be readily discoverable. In our modern construction, carried to a high degree in the differentiation of parts, we find these reasons which were not evident in lesser works.

Another piece of construction, called "false" by some critics, is reached here, too. That is, the use of an arch or stone lintel at certain levels, with a girder behind it or over it, which, it is said, does all the work. It is true the girder does the work of sustaining the load and as a tension member to tie the piers supporting it. But the arch has its duty also. It is a most effective means of holding the piers apart, resisting any tendency which they may have developed to close inward, and, as it carries no weight but its own, its thrust is abundantly met by the ties and the mass of the piers, and an equilibrium of great strength is maintained. And for this same stiffening effect, as well as for æsthetic reasons, a storey may be introduced in one or more places which deals with the front as a whole, not as piers and lintels, but as a wall of the full thickness, with openings through it. Pleasing contrasts may be obtained by dividing certain sections into three windows instead of two, and this without any imperfections in structure. The sky-line is sometimes broken by gables or dormers, and sometimes as severely horizontal as a Roman might have designed. Either method is permissible, and the authors of this style are not afraid to use the simpler motive when circumstances require. Then the lack of light where it is most needed—namely, on the ground storey—often prompts the placing of the first main arch or lintel over this or even over the second floor, instead of at the foundation. Lastly, the monotony of the equal storeys is varied by collecting them in unequal groups. Thus we arrive at the fully developed phase of a most simple and dignified composition for the front of a modern heavy building of the commercial class, which is, to sum up, a façade of many storeys divided horizontally into a few main groups. These are contrasted in proportions by including one, two or three floors. The vertical elements are widely-spaced continuous main piers, forming openings subdivided by small piers discontinuously in the different groups.

This analysis of some of the motives of modern design, and the construction from which it arises, reveals the close relationship of all the best work of this class, however varied in treatment of detail. Its truths are alike expressed in the Romanesque work, which is so fast growing in favour throughout the country, in the scholarly Renaissance of New York, and in the more free arches of Chicago. The principles are the same, and the necessities and the solutions of the problem, by different heads and hands, have that in common which constitutes a new school of architecture, and which, with the prevalent strong and able treatment of the noble round arch, promises to establish a national style. Already it is begun, and we have a right to expect more of the future than we have received in the present.

**New Premises** have been erected for the Express Dairy Company at Hampstead, the ventilation of which is carried out on the Boyle system, the latest improved form of the patent self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

## THE WASHINGTON MONUMENT.

THE November number of *Stone* (Indianapolis) says great care is taken to note the movements of the Washington monument, for it does move. The law of contraction and expansion of material by heat and cold operates here as elsewhere. When the sun shines full on the eastern face in the morning, the stones on that side expand and throw the shaft slightly to the west. Then the sun goes around to the south, and the apex of the monument makes a corresponding swing to the north. As the orb creeps about the sky to its final setting in the evening, the glittering point on the top of the monument makes a contra-movement around half a circle, gradually settling back to its normal position after the rays of the sun have lost their power. This movement has never been calculated, but is undoubtedly very slight. The wind, too, has an effect upon the structure. From the centre of gravity of the shaft, located 174 feet and 10 inches from the floor, is a cross-beam from which is suspended a fine steel wire, protected by a galvanised iron tube about 4 inches in diameter. This hangs to the floor at the north-west corner of the elevator well. At the bottom is a plumb-bob weighing 25 lbs., suspended by means of the wire, and hanging in water. An iron cylinder protects the instrument from injury, and a little iron house 4 feet high keeps off the draught. Through the cylinder is a telescopic eye-piece, in one end of which are two vertical wires about one-quarter of an inch apart. When a candle is held at an opening in the side of the box and the eye is applied to the outside end of the tube, the plumb-line can be seen—a fine line between the vertical marks. Any movement in the shaft is recorded by a corresponding movement in the line. When the structure is at rest and in its normal position, the line hangs still midway between the others; but when the shaft is disturbed by the action of the wind it sways back and forth like the pendulum of a clock, always coming to rest in the centre. This is observed every day, and if the custodian should ever notice the line hanging still at any point outside of the two cross lines he will then know that the monument has been permanently moved from its level position. Until then, however, no one need be alarmed by the oscillations of the shaft from the action of the wind or the influence of the sun.

## CHURCH BUILDING AND RESTORATION.

**Granby.**—The parish church, All Saints, has been reopened after restoration. The architect is Mr. Edward Turner, Bloomsbury Square, London. The contract for the work was let to Mr. H. Green, Waterway Street, Nottingham. The woodwork has been supplied by Mr. H. Scott, Sherwood Street, Nottingham; the lamps and the lamp frames by Mr. F. Coldron, Brant Broughton; and the windows by Mr. H. Holmes, Arkwright Street, Nottingham.

**Langley.**—The committee of the Langley New Town Mission Church, Bucks, having instructed their architect, Mr. Albert E. Pridmore, of 2 Broad Street Buildings, to prepare the necessary plans, &c., that gentleman has forwarded two separate schemes, which will be discussed and the course to be adopted decided at the next meeting.

## GENERAL.

**M. Auguste Cain** has been commissioned to execute a group in bronze, *Combat of Lions*, for one of the public places of Copenhagen.

**Mr. H. T. Ashby** read a paper on Thursday before the Institute of Builders upon "Quantities."

**Mr. H. A. Jones, F.S.I.**, has opened offices at 11 Wellington Street, Strand, as a surveyor, valuer, and house and estate agent.

**Sir J. A. Picton** will read a paper on "The Successive Town Halls of Liverpool" at the meeting of the Liverpool Architectural Society on Monday.

**The Bishop of Salford** has purchased Moston House, Harpurhey, for an establishment for a religious sisterhood.

**Plans are being considered** for the immediate erection of a church at Lostock, in compliance with the unanimous desire of the population of Lostock Junction and Lostock Park.

**A Church House** is to be founded in Liverpool for the various diocesan organisations.

**A Town Hall** is proposed to be built at Aberfeldy, and a committee has been appointed to obtain subscriptions.

**Extensive alterations** and improvements are being carried out at Himley Hall, Staffordshire, where Lady Dudley intends to take up her residence early in January.

**The Liverpool Improvement Committee** have agreed to pay 90% per square yard for land to be taken for the widening of Church Street.

A Business Supplement

# The Contract Reporter.

to The Architect.

LONDON, NOVEMBER 23, 1888.

## COMPETITION OPEN.

CHERITON.—Nov. 29.—Premium of 50*l.* is offered by the Guardians of Elham Union for the best method of Sewage and Rainwater Disposal. Mr. R. Lonergan, Saltwood, Hythe, Kent.

## CONTRACTS OPEN.

BLACKHILL.—Nov. 24.—For Building Small Farmhouse, &c. Rev. J. J. Cundhill, Muggleswick Vicarage, Blackhill, Durham.

CHILBOLTON.—Dec. 1.—For Building House. Mr. John Hillary, Architect, Longparish, Hants.

CLECKHEATON.—Nov. 26.—For Erection of Public Baths. Mr. R. Castle, Cleckheaton, and Mr. W. H. Howarth, Cleckheaton, Joint Architects.

DOVER.—Nov. 24.—For Building Premises, Cannon Street, for Messrs. Wright Bros. Messrs. Cresswell & Newman, Architects, 54 Castle Street, Dover.

DOVER.—Nov. 27.—For Construction of Store and Shed, at Stembrook. Mr. E. Wollaston Klocker, Town Clerk, Castle Hill House, Dover.

EARLSHEATON.—Dec. 10.—For Building Power Loom Sheds, Engine and Boiler-houses, and Long Chimney. Mr. F. W. Ridgway, Architect, Church Street, Dewsbury.

EAST DONYLAND.—For Building Four Almshouses for Lady Alfred Paget. Mr. F. Evelyn Morris, Architect, West Stockwell Street, Colchester.

HAMPTON-ON-THAMES.—For Building Two Pairs of Semi-detached Villas. Mr. Frank Roberts, Surveyor, 110 Cannon Street, E.C.

HASTINGS.—Nov. 30.—For Building Mixed School and Offices at Ore. Mr. F. H. Humphreys, Architect, 6 Trinity Street, Hastings.

KNUTSFORD.—For Building Manse. Mr. J. H. Burton, Architect, Warrington Street, Ashton-under-Lyne.

LANDPORT.—Dec. 4.—For Erection of Stands, &c., in Drill Hall, for the Annual Tournament. Mr. A. H. Bone, Architect, Hanover Street, Portsea.

LEIGH.—Nov. 31.—For Alterations to the Town Hall, for the Leigh Local Board. Mr. J. C. Prestwich, Architect, Leigh.

LEIGH.—Nov. 31.—For Painting, Paperhanging, Decorating at the Town Hall, for the Leigh Local Board. Mr. J. C. Prestwich, Architect, Leigh.

LONDON.—For Building Food Dépôt, Edgware Road. Mr. J. Williams Durnford, Architect, 101 Queen Victoria Street, E.C.

NELSON.—Nov. 26.—For Building Pair of Semi-Detached Villas. Mr. H. Whitaker, Architect, Nelson.

PITSLIGO.—Nov. 26.—For Building Parish Church. Messrs. Matthews & Mackenzie, Architects, 255 Union Street, Aberdeen.

PONTYPRIDD.—Dec. 5.—For Building Arcade, with Shops, Cellars, &c. Messrs. Taylor & Evans, Architects, Cardiff.

SLOUGH.—Dec. 13.—For Building the Leopold Institute. Mr. H. A. Cheers, Architect, Twickenham.

WEYMOUTH.—Nov. 26.—For Alterations and Additions to Workhouse and Premises. Mr. R. C. Bennett, Architect, 10 Gloucester Terrace, Weymouth.

WINCHMORE HILL.—Nov. 23.—For Two Additional Pavilions and Additions, &c., to Administrative Block, Northern Hospital. Messrs. Pennington & Bridgen, Architects, 8 John Street, Adelphi, W.C.

## TENDERS.

### BIRMINGHAM.

For Laying Pipe Sewers (4½ miles), Yardley, Olton and Dorridge, and Laying-out Lands for Irrigation purposes, for the Solihull Rural Sanitary Authority. Mr. F. SMYTHE, Surveyor.

Jones & Fitzmaurice, Birmingham . . . . .	£7,681	0	0
Jevons & Son, Dudley . . . . .	7,214	0	0
Curral & Lewis, Birmingham . . . . .	7,010	0	0
J. Biggs, Birmingham . . . . .	5,870	0	0
LAW, Kidderminster (accepted) . . . . .	5,665	0	0

### BIRKENHEAD.

For Patent Hot-water Heating Apparatus for Hall and Conservatory at Roseneath, Prenton Road West, for Mr. Charles Sandell.

RENTON GIBBS, Liverpool and Birmingham (accepted).

### BRIGHTON.

For Terrace Walk, Madeira Road (1,300 feet in length), Enclosed Shelter Hall, with Rooms and Lavatories attached, Hydraulic Lift, and Works in connection, Brighton. Mr. PHILIP C. LOCKWOOD, Borough Surveyor, Town Hall, Brighton.

G. G. Garbutt, Brighton . . . . .	£21,538	0	0
W. J. Botterill, London . . . . .	17,998	0	0
J. G. B. Marshall, Brighton . . . . .	17,990	0	0

## TRADE NOTES.

THE iron miners employed by the Barrow Steel Company in the furnace mines have decided to accept the masters' terms, the advances ranging from about 1d. to 6d. per day. The dispute affected over 2,000 men.

THE Boys' Roman Catholic School, Dockhead, London, S.E., is warmed and ventilated by means of Shorland's patent Manchester stoves, supplied by Mr. E. H. Shorland, of Manchester and London, Mr. Leonard Stokes being the architect.

IN connection with the re-opening of Moniash Church, Derbyshire, a handsome brass eagle lectern has been presented by Mr. George Greaves, of Sheffield. The eagle, which is of massive proportions, stands upon a ball supported by a richly ornamented shaft and capital, with a solid base and three large lions at the foot. The work has been carried out by Messrs. Hardman, Powell, & Co., of Birmingham.

MESSRS. JONES & ATTWOOD, of Stourbridge, have just completed the heating of the Baptist Church, Moseley, near Birmingham, and the Primitive Methodist Chapel at Quinton, near Birmingham.

THE City Commissioners of Sewers on Tuesday decided to issue notices for the acquisition of all interests outstanding, so that the improvement of Fetter Lane may be completed without delay, and the land belonging to the Commission, which has been vacant for a year or two, built upon.

WE notice that Messrs. Kelley & Co.'s address is changed to 23 Castle Street, City Road, E.C., their address having been previously 24 Castle Street.

MR. JOHN GRUNDY, of London and Tyldesley, is engaged in heating Sherborne Abbey for the architects, Messrs. Carpenter & Ingelow, and on Thursday last week the workmen at the Abbey, in excavating along the main aisle, came across a heavy lead coffin resting in its vault, which, unless removed, would have been in close proximity to the heating apparatus. It was found to contain the body of a young lady, apparently about twenty years of age, and evidently a person of high social rank, the features being those of an exceedingly good-looking person, and found to be perfect. The coffin lay in a brick vault at the west end of the main aisle, and had been buried in the orthodox fashion with the feet towards the east. There was no plate, and the probability is either that it had been stolen during the early history of the church or had somehow disappeared. The outer oak encasing the lead had

entirely rotted away. The opinion is that it must have lain there for seven or eight hundred years at the least.

MESSRS. CLARK, BUNNETT, & Co. (Limited), engineers, in reference to the recalcitrant iron curtain at the Shaftesbury Theatre, write: "We, as the manufacturers of that curtain, desire to explain that there was no defect whatever in our machinery, but that, owing to the want of proper oiling and attention, the valve of the curtain simply jammed. It has now been cleaned and oiled, and the curtain is in good working order."

MISS GRACE HAWTHORNE has given permission for a ticket benefit at the Royal Princess's Theatre on Monday, November 19, to Friday, November 30, on behalf of the Christ Church East London Halfpenny Dinners. All tickets bought direct of Mrs. Priscilla Jay, Christ Church Vicarage, Watney Street, E., will benefit the charity. Last year over 40,000 dinners were provided for 131*l.* 12*s.* 5*d.*, including all working expenses and a new cooker. This year want of funds delays the carrying out of the same object. "Hands Across the Sea," by Henry Pettitt, will be played each evening and on Saturday afternoons, and "The Love that Kills" (L'Arlésienne), on Monday, Tuesday, Wednesday, Thursday, and Friday afternoons, November 26 to 30. "The Love that Kills" is adapted from the French by Jocelyn Brandon, with the beautiful music of Bizet to L'Arlésienne, which was produced with such marked success at the Prince of Wales' Theatre at two matinées this year (the first of which was attended by H.R.H. the Prince of Wales and suite). It will be reproduced by Miss Grace Hawthorne and Miss Sophie Eyre at the Royal Princess's Theatre, with a special orchestra, ballet and chorus, at daily matinées (Saturdays excepted), commencing on Monday, the 26th inst.

#### IRONMONGERS' EXHIBITION.

THE well-arranged display of Messrs. Harry Hunt & Co., of 12 New Oxford Street and Newington Green, included samples of his excellent sanitary stoves, ranges, &c. The "Hygiene," a ventilating hall stove, by which an equable temperature is established throughout a house, is a handsome article. Ventilation is also secured by it, and while tempering the air to the required warmth an entire freedom from oppressive stuffiness is secured. Various sizes render it efficacious for use in churches, public buildings, schools, &c., as well as for mansions

and also small dwelling-houses. The "Argus" office stove is another variety of stove suitable for small halls, rooms, offices, &c. Messrs. Harry Hunt & Co. have secured other excellent results in their stoves, inasmuch as the combustion is under control, they will remain alight for months if required, and will consume coke, anthracite, and any smokeless fuel. They have also a new fireproof material for use for linings of stoves, ranges and furnaces, called the "Terra Fuego" cement, which can further be used as a wash for repair of cracks, &c., and as a surface wash also prevents deposits of carbon taking place.

Messrs. F. Whitfield & Co., of Oxford Street, Birmingham, who are the sole manufacturers of the patent "Sicker" safe, show a new safe which has just been made by them, and is now first exhibited. It is specially intended for the use of tradesmen. This form of safe will prove most serviceable, and the cost is exceedingly small. The need of such a safe has hitherto had to be supplied by the expenditure of as much money probably in locks and bolts where clients did not require the typical safe, often too large and too costly for their purpose. The office safes also meet an extensive requirement of the day. The "Sicker" safes are known, and have gained practical success in the satisfaction they have given all round. The safes are made in various sizes and for various purposes, for business houses, private houses, for bankers, jewellers, for deed chests, plate chests, &c., and they have proved themselves in many a fire as worthy of the trust placed in them to safeguard the contents committed to their protection.

Messrs. Appleton, Burbey & Williamson, electrical engineers, 91 Queen Victoria Street, E.C., carry out electrical work in all its branches, erecting and maintaining installations on both the arc and incandescent systems; temporary lighting as required for lectures, concerts, balls, and other entertainments; electrical transmission of power and propulsion in all branches; motors for light work; the erection and maintenance of private telephone lines for clubs, warehouses, asylums, &c. Advice can be had from them as to the working and management of accumulators for all purposes; among these will be found a pocket accumulator for small incandescent lamps; and, further, they undertake experimental works, and the carrying out of ideas for inventors. At their stand, No. 23, are exhibited, among other matters, the patent adjustable switches for main and branch circuits, which supply the demand for thoroughly reliable and durable switches for electric light and power installations. These are in different varieties and of graduated

strengths; some have been specially designed to carry very large currents. In every case ample contact surface is provided for the amount of current to be carried. The display at the stand also includes switchboards, china switches, fuses, lampholders, ceiling roses, &c.; electrical measuring instruments, all electrical fittings and accessories, portable electric lamps and portable electric bell sets, and a new patent shade and globe carrier.

Messrs. Le Grand & Sutcliffe, 100 Bunhill Row, E.C., show their Norton's patent Abyssinian tube wells and pumps, awarded a gold medal (highest award) at the Health Exhibition, artesian well tubes, and boring tools for the same; lift and force pumps, deep-well pump-barrels for artesian wells, and double (7-inch) barrel wheel pump. The Abyssinian tube-wells have now been in use for over twenty years for permanent supplies, ranging from the requirements of a cottage to that of furnishing upwards of 300,000 gallons daily for towns, paper-mills, large breweries, and other purposes, in addition to which they have formed part of every military campaign, from the Abyssinian War down to the latest Nile Expedition. They are widely known, and it need only be said that they are simply driven into a water-bearing stratum, dispensing with the costly process of digging, while at the same time avoiding the risks of surface contamination to which dug wells are liable. They are frequently employed for deepening existing dug wells which have become polluted or run dry. As they can be withdrawn and redriven, they are very useful for obtaining temporary supplies for railway work and building operations, and for ascertaining water levels for drainage and other works. They are most suitable for gravel, coarse sands, chalk, and porous water-bearing strata, not being recommended for clays, marls, and fine sands. In strata that cannot be penetrated by them, and rock, an artesian well tube must be bored, and it is well known how successful Messrs. Le Grand & Sutcliffe are in these undertakings. The Norton's improved patent registering turnstiles, of which this firm are the patentees and sole makers, are also shown; but these are well known, another variety being the exit cage turnstile.

Messrs. King & Smith, 59 Haymarket, S.W., and the Stowe Works, Weedon, show an excellent arrangement for the cellar in their patent "Honeycomb" wine bin, and to which a gold medal and diploma of honour were given at the Anglo-Danish Exhibition. The construction of this wine bin is fairly claimed as a novelty. Each receptacle for a bottle is a separate tube made of terra-cotta, hexagon or honeycomb shape outside, and

circular within—just large enough to take a bottle easily—and, as the circle is only slightly larger than a bottle, the bottle beds down into the lower part and will not roll or shake about. The tubes are stacked in honeycomb fashion, in any space desired to be fitted up as a wine bin, and require no kind of fixing, as they fit into each other, and from ten to twelve tubes go to one square foot of wall surface. The advantages are obvious.

The Bostwick Gate and Shutter Company, Limited, 73 Queen Victoria Street, have fixed up various folding gates and shutters as samples of their useful specialties, which are well known also for their ornamental qualities. There is a folding steel dwarf gate for doorways, &c., folding steel gate for lifts and passages, and folding steel shutters for windows, applied

either outside or inside. The wonderful ease with which these gates and shutters open and close is remarkable, and they afford in the best of methods a most perfect protection, without causing the slightest obstruction of light or of air, and, as before said, the highest ornamental effect can be added. The sketch we give of the Bostwick Gate will convey some idea of an arrangement which has none of the commonplaceness of ordinary gates.

Mr. James Gregson, of Bath Street, Bolton, the patentee of the "Perfectum" wall-pipes, &c., shows the newest and most perfect way of dealing with down spouts or stack-pipes, in full size and of various forms, with a novel variety of hangers, clips, and other fastenings, for pipes of other makers. These pipes are a perfect protection against damage and disfigurement of outside walls; also of the plaster and paperhangings inside rooms, through defective down spouts. They are very easy to fix and renew, because the nails, which are always intended to remain in the wall, are first driven into a joint within half an inch of the head. The "Perfectum" is quite an improvement on any down spout hitherto made, it having a 7-inch socket for sliding to wall-joints, which saves drilling and plugging, and for sliding out broken middle lengths for renewal without removing others or drawing the nails. It simply hangs on the nails just 1 inch from the wall to convey any escaping water clear down the pipe without wetting the wall, and to allow of their being painted all round. Each pipe hanging on its own nails, and not resting on the bottom of the 7-inch socket (which is bevelled inside), it will not retain the rust and dirt which accumulates between old-fashioned pipes in short sockets, which can seldom be separated without breaking two or three lengths, drawing the nails, and damaging the brickwork.

Messrs. Griffiths Bros. & Co., 4 Dashwood House, New Broad Street, E.C., and Bermondsey, have an exhibit that is well worth a long inspection in the samples of their manufactures of paints, varnishes, enamels, &c., which have been described at length in our columns before this. Specimens of executed work also to be seen at the stand afford a fair means of judging of the excellence of the manufactures. The oxidised enamel paints patented many years ago have become so much in demand, not only for the general business, but for decoration, for domestic purposes for re-enamelling baths, &c., and articles of metal, that a new department has been opened by the firm for their supply, in suitable tins and quantities ready for use.

Messrs. Abbott & Co., Newark-on-Trent, have on view their "handy hoist," which is well described as the cheapest machine for light weights ever offered. It is easily fixed, easily worked, easily kept in order, and easily repaired, and the worm and wheel gear will hold the weight in any position without running down. The No. 4 hoist has two speeds. It enables one man to lift 10 cwt. with the worm and wheel gear at a slow speed, and 2½ cwt. at a quick speed with the bevel-wheel gear, and to

lower by brake if desired. There is no business that requires a lift at all where this will not be found useful. The No. 5 hoist is for light weights (2½ cwt. with one man), and will save having an extra man in thousands of cases, and the cost will be saved possibly in less than six months, even when only occasionally used. The cost of these hoists is, too, exceedingly small.

Messrs. C. Portway & Son, "Tortoise" Stove Works, Halstead, Essex, show the patent slow-combustion close stoves. They are especially adapted for church and school heating, being simple in construction, easy of management, economical in consumption of fuel, and burning long hours without attention. The entire interior consists of Stourbridge clay ware, including the hearth on which the fire is laid; consequently no smell of burned iron can be perceived, as the fire comes in contact with the clay only. The stoves have proved a success, being both efficient and economic, and their merits have long been recognised by the public.

Messrs. Dick, Kerr & Co., of 101 Leadenhall Street, London, and 98 Mitchell Street, Glasgow, show the "Griffin" gas-engine, one of 6 horse-power, of double-acting horizontal type (as in the accompanying illustration, and which ranges from 1 to 20 horse-power), that drives a dynamo for lighting various ex-

hibits. A 2½ horse-power "Griffin" gas-engine, double cylinder single-acting vertical type, drives dynamos for lighting Messrs. Dick, Kerr & Co.'s own stand. Among the others is a ¼-horse power "Griffin" gas-engine, for driving rotary pump or hoist. These engines are notable for simplicity and economy, while their cost is small.

WORKS, ROTHERHAM. Estab. 1854.

The accompanying sketch will explain a new patent lock shown by Messrs. Brown & Green, of Luton and Finsbury Pavement, E.C., when examined with the following description:—1. Self-acting latch working on pin 6; 3. Locking bolt, which, when thrown by the key over pin 5 against the latch-bolt at 2, effectually locks it, and the reverse action of the key unlocks it in the same manner. 4. Follower for working latch in the usual way. Attention should also be called to this firm's valuable patent "Grip" axle sash pulleys, as being the best,

strongest, simplest, and most secure. In fixing them no screws are required. It is only necessary to bore three holes and drive them in and they will be firmer without screws than the ordinary pulley is with screws. They do not weaken the pulley stile, are easily oiled, and the wheels revolve freely. The ranges and stoves exhibited deserve notice. Several simple improvements have with much ingenuity been thought out and carried into effect, which should be inspected. A marvellously cheap warming stove, on the slow and regulated combustion principle, is to be seen in the "Magnet" stove.

Harrison's new blind-line clutch (Mr. J. Harrison, Castle Bytham, Stamford) is a marked improvement (on a new principle) on other systems. The clutch takes hold of the cord very like one would do with the thumb and finger, the grip regulating itself automatically as the weight upon the cord is varied—the greater the weight to be sustained the greater the grip upon the cord; at the same time it will pass quite freely through the clutch when drawn in the opposite direction. The clutch is composed of two arms moving in the same plane, but pivoted on different centres; the lower arm is slotted at the outer end, the upper arm being shaped to pass through the

slot, and is turned upon the under side to form a hook to which the loose end of the cord is fixed for the purpose of drawing the clutch out of action to lower the blind. The cord is passed through (to the blind-roller pulley) the slot in the lower arm, and is clutched between the end of the upper arm and further end of slot. The arm pivots are placed to cause the end of the upper arm to slide outward in the slot and close upon the cord when the arms are moved in the direction of the pull upon the cord; therefore a slight pressure upon the cord between the two arms is sufficient to draw the arm with the cord, the grip increasing with the weight to be sustained. The arms are held up by a spring to give the slight required pressure on the cord. The action of the clutch is such that, were it made of sufficient strength, it would hold an ounce or a ton weight, and only give just the required grip in each case. The clutch is simple, with nothing to get out of order; it cannot damage the line, and is applicable to ventilators, trap-doors, &c.

The stand of Mr. A. G. Hamilton (No. 123), artificer in wrought-iron, forms one of the most interesting exhibits, not only for the variety and excellence of design and workmanship, but also for the artistic manner in which it is fitted up. He has erected the "Quintin Matsys Forge" as an ancient cottage, much resembling one of the workshops in "Old London" at the late South Kensington Exhibitions, which admirably shows off the specimens of wrought-iron work he is exhibiting; one of the best is a gong, a beautiful example of scrollwork. Standard floor lamps, kettle-stands, music-stands, banner-screen stands are shown, all possessing artistic merit; also wrought-iron swinging lamps of handsome design. A specialty is made by Mr. Hamilton of wall-lamp brackets and electric-light fittings, the latter being specially worthy of notice. Mr. Hamilton has a large number of articles on show at his works, The Quintin Matsys Forge, 14 Griffen Street, York Road, London, S.E., where we would recommend our readers to pay a visit.

At stand No. 97 Mr. James Dickson, of 48 Gray's Inn Road, has a fine show of patterns of every description of wire-work. Lime and sand screens for contractors' and builders' use, both socket and laced, sieves of every kind, and for all purposes, in brass, copper, tinned and ironware, paint strainers; also Watson's patent ventilating cowls and gas stoves. The firm was established in 1769, and maintains its high reputation for good workmanship.

Messrs. Mainzer & Kempthorne, of Bloomsbury Mansions, Hart Street, W.C., are showing several samples of their marble mosaic pavements. The choice of design and colour is very

Office: 28A UPPER GEORGE STREET. EDGWARE ROAD, W.

varied, and ranges from plain work to very elaborate and artistic treatment. We were specially struck with the freedom of the designs and the excellent workmanship of the samples exhibited. Messrs. Mainzer & Kempthorne inform us that, by an improved method in the manufacture of their marble mosaic, they are enabled to carry out work at greatly reduced prices.

We have already referred to many uses to which silicate cotton can be applied as a fire preventive. Its most recent development is in the direction of mitigating the extreme climatic influences of heat and cold. The interior of an iron building, for instance, is padded with silicate cotton covered with wire, and the consequence is that neither heat nor cold can penetrate. It would be impossible to give better illustrations of its uses than that the Russian military authorities have adopted it in their portable huts on the Galician frontier, to mitigate the extreme cold in winter, and that it is used in India as a protection against heat. Silicate cotton is also a non-conductor of sound as well as heat and cold; and these inestimable advantages suggest its application generally, not only to iron but to buildings of every description. From actual tests a 1-inch padding of silicate cotton is a better protection against cold than 12 inches of brickwork. There is no question that this excellent provision for comfort is rapidly forcing its way to the front from sheer merit.

In referring to Mr. F. Benson's exhibit of iron wine bins at the Ironmongers' Exhibition in the last issue of *The Architect*, it was erroneously stated that the "lathe is used in turning." The correct reading should be, "the lathe is used in binning."

The St. Pancras Ironwork Company have contented themselves with exhibiting two beautiful models, one representing a complete stable, exquisitely-fitted, with every improvement of sanitary paving, drainage, ventilation, &c. The other model is one of an elegant spiral staircase.

Messrs. Ewart & Son, 346 Euston Road, have the "Lightning" geyser shown in various sizes, and its name aptly describes the rapidity with which hot water is discharged into the baths, which also form part of the exhibit.

Mr. Robert Adams, 67 Newington Causeway, S.E. (Adams's Building Trades Emporium), shows a new principle developed in the Victor spring, by which the door closes itself without any rebound, but with a barely perceptible check. If the door be closed with a bang no injury would result. This obtained a gold medal (highest award) at the Cardiff Exhibition. An improved rising butt is silent in action without rebound in closing door, which can be set open for any length of time.

Mr. Robert Adams shows enamelled slate chimney-pieces (Messrs. Corfield & Morgan, Albion Slate and Marble Works, Cardiff), and designs of the same in white marble. The whole of the work will be able to be seen at the emporium after the close of the Exhibition, as representative stock will be kept there. Messrs. Corfield & Morgan also obtained the gold medal (highest award) at the Cardiff Exhibition. Mr. Samuel Elliott, of Newbury, whose excellent wood mouldings we have often before alluded to, shows the Elliott's patent "perfect simplex" metal weather-bar for casements opening inwards, and all existing windows and doors, to which a medal was awarded at the Brussels Exhibition this year. Messrs. Carter & Aynsley's (54 Bishopsgate Street Without) specialties in lock and door furniture, altar fittings and brass-work fittings, &c., cannot be overlooked by visitors, and the elegant mahogany and glass structure containing them, besides having a prominent position, affords every opportunity of examining the excellent work of this firm. Messrs. Charles Toope & Co., Stepney Square, E., show their patent Champion and Perfection boilers, which are invaluable to the owners of glass-houses where heat is required. There are also their eclipse heaters, patent propagators, and patent garden frame heaters, which supply the purposes long wanted. Mr. Thomas Heron, 88 St. John's Road, Upper Holloway, shows the efficiency and economy of his patent duplex gas-burner over the ordinary kind by direct contrast: two model gas-meters supplying respectively an ordinary and a patent duplex burner. These are introduced at the Houses of Parliament, at Dr. Quain's, Harley Street, and at Sir Andrew Fairbairn's, Portman Square. A new burner, shown for the first time, gives 100 candle-power to 12 feet of gas. The patent "Bland" copying machine is seen at work at the stand of Messrs. William Bland & Co., and the specimens executed leave nothing to be desired. The patent ball-bearing castors are also shown. The offices are at Grey Friars, Leicester. Messrs. Arden Hill & Co., Etna Foundry, Birmingham, show the patent "Acme" metal, fires an admirable system of warming, giving great scope for ornamental effect. The "Phoenix heater" is a powerful oil stove free from smoke or smell, of highly ornamental type, shown by the makers, Messrs. S. Clark & Co., of the Syphon Works, Islington, at their stand, and is most valuable for sitting and bed rooms, conservatories, &c. Mr. Charles Gay Roberts, of Haslemere, shows his well-known rain-water separator; Mr. James Adams, 7 Union Street, Borough, the "Slave" pneumatic check-door spring

## CONTRACTORS TO H.M. GOVERNMENT.

INTERNATIONAL HEALTH AND OTHER EXHIBITIONS—MEDALS AWARDED FOR

# LEGGOTT'S PATENT ADJUSTMENT

CONTINUOUS OPENER.

SILENS.

THE SILENS, for Fanlights, Skylights, &c. Is admitted to be the best ever put before the Public. Can be adapted to any kind of window. Size and height of window no object.

From 4/3 each.

The WILMOS is worked with a rod or endless cord. It is extremely neat, and can be fixed to open either top or bottom, inwards or outwards; no cutting away of frame required. When worked with a rod is most efficient for Public Buildings, as the key can be loose. For Price Lists, Illustrations, and Testimonials, write as below.

For Continuous and other Lights, Estimates given.

WILMOS.

NO CUTTING AWAY OF FRAME REQUIRED.

### TESTIMONIAL.

SIRS,—I have pleasure in testifying that I have used Leggott's Silens Adjustments for various buildings to high skylights, fanlights, and top parts of windows, and in every case they gave satisfaction.

They are secure in whatever position, whether the window is open or closed, and are quite simple and workable in their action. I prefer them to any other that I have seen or used for the above-mentioned purposes.

Messrs. W. & R. LEGGOTT, Bradford.

I remain, yours obediently,

R. DAVIES Architect.

Considerably Reduced Price List, November 1, 1887.

ALL WORK ENTRUSTED TO US GUARANTEED SATISFACTORY.

**235 HIGH HOLBORN, LONDON, W.C.;**  
**109 HOPE STREET, GLASGOW; SILENS WORKS, BRADFORD.**

TELEGRAPHIC ADDRESS—"SILENS BRADFORD."

hinges; and Messrs. Willing & Co., Limited, Clerkenwell Green, their patent enamelled copper letters and enamelled iron and patent electric signs. Messrs. Hindle, Norton & Co. show their "Acme" door check and spring in various kinds, which have taken highest awards at Edinburgh, Adelaide, York, and Bolton Exhibitions. Mr. H. L. Müller, of 22 Mary Ann Street, Birmingham, shows the Müller Alpha patent gas-making machine, which has made so great a revolution in supplying lighting requirements in so many directions. It is familiar to manufacturers, and is appreciated for its steadiness and uniformity in working as well as for its economy.

#### NATIONAL REGISTRATION OF PLUMBERS.

A LARGE public meeting of plumbers, architects, and others was held on Wednesday evening in the Technical School, Belfast, Mr. J. Mackenzie, C.E., presiding. Mr. F. W. Smith mentioned the steps which had been taken to form a class for instruction in plumbing work in co-operation with the Worshipful Company of Plumbers, London. It was resolved "That it is desirable steps should be taken to form a local Council to co-operate with the Worshipful Company of Plumbers in support of the system of registration as laid down in the rules of the guild."

Ex-Provost Moncur presided at a meeting just held at the Technical Institute, Dundee, on the occasion of the opening of plumbers' classes there; and at the monthly meeting of the Registration Committee at the Guildhall on Thursday, about 750 fresh applications for registration were reported, 200 being from master plumbers and 550 from operatives. About 600 of the applications were received from the District Councils acting in conjunction with the Plumbers' Company in the provinces.

Plumbers registered since October 1, 1888:—

AMERICAN NOTES.

A SAN FRANCISCO Syndicate has purchased a tract of timber land, containing 625 square miles, in California from the Central Pacific Railroad Co. This tract is densely covered with large sugar pine-trees. It lies west of Lake Tahoe in the northern part of El Dorado Co., and has been left intact owing to the lack of transportation facilities. The present company proposes to build a flume to Folsom, 50 miles distant, and spend about 1,000,000 dols. in opening up one of the most magnificent timber tracts in California.

A refuse destructor has been constructed, at a cost of 11,000 dols., as an experiment at Chicago. The furnace has been in operation since last April. The capacity is 150 tons per day, though it has never been pushed to its utmost, owing to the expense of cartage. During June the furnace consumed 103 tons daily for twenty-six working days, at a cost of 25½ cents per ton for labour and coal, exclusive of the cost of delivering the refuse. With 150 tons daily this cost could probably be reduced to about 17 cents per ton.

LIVERPOOL MASTER BUILDERS' ASSOCIATION.

THE annual banquet of the Liverpool Master Builders Association was held on the 15th inst. Mr. J. Stevenson Jones president of the Association, was chairman.

Mr. A. G. White proposed the toast of "The Mayors and Corporations of Liverpool, Birkenhead, and Bootle."

The Mayor of Bootle expressed his regret that the Mayors of Liverpool and Birkenhead were prevented being present. Alluding to the advance that had been made in the population and importance of Bootle in recent years, Mr. Wells said in 1868 the population of Bootle was 15,000; they had 2,000 houses, and the rateable value was 64,000/. In 1871 the population had increased to 16,000, in 1881 to 27,000, and it now stood at 51,000. The number of houses in 1871 was 2,500; in 1881 4,300, and now it was 7,000. The rateable value of property had increased from 64,000/. to 400,000/. In fact, the increase had been marvellous. He considered that the ratepayers of Bootle had been wise in choosing some builders to represent them in the Corporation. He thought there were several men who were members of that Association who had done honour to themselves as builders and as members of the Corporation of Bootle.

TURPIN'S

PARQUET FLOOR,

Speciality: OAK AND DARKENED OAK.

Mr. Pendleton proposed "The National Association of Master Builders." It was, he said, a very important Association, representing as it did masters in thirty-seven of the principal towns in Great Britain. It was established something like ten and a half years ago, and its career had been thoroughly prosperous. Their local Association had been assisted very much indeed by the strenuous efforts which the National Association had made for the benefit of the building trade. He expressed the hope that the deepest interest would be taken in the Employers' Liability Bill, which was a very important measure, and considerably affected their trade.

Mr. J. C. White, whose name was joined to the toast, said at the present time the National Association was particularly engaged with the question of the Employers' Liability Bill, which had recently been before Parliament, and was to come on again. They preferred the old Bill to the new one. Under the circumstances he thought that the Government Bill, as amended, would fall to the ground. All the employers wanted was justice between themselves and their men, but they did not consider that they had it in either of the Bills proposed. He did not think that the building trade throughout the kingdom generally, or the British public as a whole, had paid sufficient attention to that Bill. It meant a great deal to them in the future; it meant that their houses would cost them a great deal more money, and it would also entail on them other expense. Messrs. Broadhurst and Burt wanted the limit of liability to be 500*l*. The Bill as it was framed showed no favour to the builder whatever, but practically rendered him responsible for every accident, no matter how much the individual employed be responsible for that accident. They therefore considered that the master builders were most unjustly treated, and that some change in the Bill was needed.

Mr. Royden, M.P., explained that he was a member of the Parliamentary Committee to which Mr. White had alluded, and therefore thought he ought to say a word or two in regard to the Employers' Liability Bill. They had a very long discussion upon the merits of that Bill, clause by clause, and there were several large employers of labour upon that committee. They all desired to be generous to their employes. The employers of labour upon that committee and the committee generally were most anxious that in all the clauses they should deal in the most liberal and generous spirit with those of their unfortunate workmen who might come to some injury in the course of their trade. The representatives of the workmen

wished the limit to be 500*l*., and wished a further concession in regard to other matters. It was urged by them that a man's life was of value to all those who were dependent upon him, and that the least amount at which that life ought to be assessed was 500*l*. He pointed out that in giving a certain amount of damages they did not desire to assess the value of the life of any man. It was quite impossible to put a value upon any man's life, because the life of the humblest workman in their employ was as valuable as the life of any of them. Therefore, no one should attempt to value that life at a mere monetary value. But a penalty was fixed rather as a means of causing every employer to take the utmost precaution that human skill, foresight, and intelligence could devise for the protection of his workmen. That was their object in fixing a penalty. In fixing a penalty of 200*l*. or 250*l*., it was thought that, apart from the question of humanity or goodwill to the workmen, employers would guard with the most jealous care and devise every means they possibly could for the perfect safety of the lives of those they employed. Then the question of common employment was in his opinion a perfectly fair and legitimate reason why the employer should not be liable under those circumstances. He was exceedingly sorry that the representatives of the men had found it their duty or their interest to oppose the Government Bill. His own impression was that it was conceived in the fairest and most generous spirit towards them so far as the members of the committee were concerned. While the committee and the House of Commons must of necessity act with the strictest and most impartial sense of justice towards employers, they were equally desirous to act in the most generous spirit towards working men, be their trade whatever it might.

Mr. G. E. Grayson proposed "The Liverpool Master Builders," and mentioned the great service that the Association had done towards preventing those unhappy strikes which formerly entailed untold misery upon the workmen and those dependent upon them, diverted capital away from building speculation, and caused a ruinous loss to the employers.

Mr. Green, who replied, said that the Association tried to defend not only the master builders but their employes as well, and they felt that undue pressure was put upon them in the Bill which it was proposed should be passed into law.

The other toasts were "The architects, surveyors and civil engineers," proposed by Mr. C. Tomkinson and responded to by Mr. Blair (surveyor of Bootle) and Mr. Thorburn (of Birkenhead); "The iron trade and kindred associations,"

### NOTES ON NOVELTIES.

**Water Supply.**—It will be interesting to our readers, no doubt, if we refer to the merits of the Davey safety motor, manufactured by Messrs. Hathorn Davey & Co., of Leeds, in its application to pumping purposes. The firm have a decided pre-eminence for motors of every description, particularly for those of small size, such, for instance, as we illustrate below. This is the desideratum for the water supply of country-houses, public institutions, &c., and since its introduction in 1884 it has met with uniform success. It has many obvious advantages over anything of its kind, and has the power of much larger motors, requiring of course less

room and less fuel. Absolute safety is insured from the fact that the Davey motor is a vacuum engine of simple construction, worked by steam at atmospheric pressure, whilst other essential advantages are that the motor is practically noiseless, and from its extreme simplicity dispenses with the services of an engineer. We do not think that a more modern, complete, or

efficient motor is to be found, and no doubt many of the difficulties in obtaining a perfect water-supply which an architect meets with would be removed by its use. Its merits may be briefly summarised as safety, simplicity, efficiency, and economy.

### PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

#### APPLICATIONS FOR PATENTS.

16219. William Barber Press, for "Improvements in cistern-valves." November 9, 1888.  
16234. John William Henry James, for "Improvements in apparatus for calcining cement materials, hydraulic lime, plaster of Paris, and like substances." November 9, 1888.  
16262. Percy John Neate, for "Improvements in apparatus for the manufacture of Portland cement." November 9, 1888.  
16285. Joseph Thomas Nicholls, for "A new window-sash holder and burglar-proof bolt." November 10, 1888.  
16307. George Watson, for "A reversible hydraulic gas-valve to be fixed between retort and gas main on retort bed, applicable also to regenerative furnaces." November 10, 1888.  
16323. Auguste Victor Bouvier and Jules Billoré, for "Improvements in the manufacture of bricks, tiles, and other like articles." November 10, 1888.  
16357. Thomas Mostyn Norris, for "Improved fastener for holding in position short window curtains." November 12, 1888.  
16365. William Brett, for "Improvements in a new fire-escape and apparatus connected therewith." November 12, 1888.  
16408. John Sharples, for "Appliances for flushing the pans of water-closets." November 13, 1888.  
16410. Frederick Wilfred Scott Stokes, for "Improvements in revolving furnaces for burning, calcining, or roasting cement, lime, ores, or similar substances." November 13, 1888.  
16457. George Gordon Brodie and James Damrel Prior, for "New or improved apparatus for approximately indicating the temperature of the ovens of cooking ranges and kitchen ovens." November 13, 1888.

## GRUNDY'S PATENT WARM-AIR VENTILATING FIRE-GRATE.

The novelty, superiority, and advantage of this patent consist in the heating surface being greater than any other Fire-grate introduced to the public. It is very simple in construction, and is made in the form of a Stove, the back of which is semicircular in shape, with gills behind and smoke-nozzle on top, all cast in one piece. The same can be attached to any design of a Register or Stove front. It is very suitable for schools, class-rooms, waiting-rooms, hospitals, offices, dormitories, and dwelling-houses, from the cottage to the mansion. Design and specification post free on application.

### TESTIMONIALS.

9 Victoria Chambers, Westminster, S.W.  
SIR,—I have much pleasure in testifying to the efficiency of your patent warm-air fire-grate. It has been very successful, and given every satisfaction where I have used it.

Yours, &c., JAMES WEIR, F.R.I.B.A.,  
6 John Street, Bedford Row, W.C.

From Hon. and Rev. G. G. C. TALBOT, M.A., Withington,  
Cheltenham.

DEAR SIR,—You will be gratified to hear that the school is completely warmed by your new grate. It is the most economical and efficient that I have ever seen.

Mr. John Grundy.

### ACROSTIC.

Just listen, friends, to what folk say  
Of Grundy's patent warm-air grate,  
How with the fresh air channels they  
Not only warm, but ventilate.

Give wondrous heat, burn little coke,  
Require but slight attention paid,  
Unequalled for consuming smoke,  
No better grates were ever made.  
Do try just one of Grundy's glo,  
You then will all its merits know.

### APPLY TO

**JOHN GRUNDY,**  
Warm Air Consulting Engineer,  
30 Duncan Terrace, City Road, London.  
Works: TYLDESLEY, near Manchester.

BOX TUNNEL, G. W. RAILWAY (East End).  
CORSHAM DOWN QUARRY (Entrance from Railway).

## BATH FREESTONES.

We are prepared, as heretofore, to supply these sound  
and fine Building Stones on terms advantageous to Buyers.  
Orders promptly executed, and Blocks selected to suit  
all requirements.  
Prices quoted by return of post, and all letters to be  
addressed to

**YOCKNEY & CO. (Sole Owners),**  
CORSHAM DOWN QUARRY,  
CORSHAM, WILTS.

Note.—No Connection with the other BATH  
STONE FIRMS.

16468. Oliver Phalp, for "Improvements in skylights and ventilators." November 13, 1888.

16509. Andrew Guthrie Suther and Thomas Legat, for "Improved composition for cleansing, whitening, and disinfecting stone passages, stairs, &c." November 14, 1888.

16597. Samuel Rideal, for "Improvements in means for advertising and displaying the names of streets and places, and for giving publicity to trade and other notices, and for other purposes." (Complete specification.) November 15, 1888.

16610. John Somerville and Alexander Allan, for "Improvements in apparatus for the prevention of stoppages in gas ascension pipes, and increasing the illuminating power of the said gas." November 15, 1888.

#### PROVISIONAL SPECIFICATIONS ACCEPTED.

5932. Charles James Henderson, for "Improved means of heating the air of apartments." April 21, 1888.

8004. David Gill, for "Improvements in wind guards to protect the tops of ventilating shafts and chimneys." June 1, 1888.

14137. Thomas Edwin Bickle, for "A safety catch for lifts, hoists, cages, or skips." October 2, 1888.

14179. James George Killey, for "Apparatus for inspecting the interiors of pipe sewers and the like." October 2, 1888.

14202. Edwin Samuel Fletcher Mann, for "Improvements in apparatus for opening and shutting windows and shutters." October 3, 1888.

14364. Francis Murray Rogers, for "Improvements in fastenings for doors, windows, and the like." (Stuart Reid, New Zealand.) October 6, 1888.

14408. Arthur Jackson, for "Improvements relating to check, feed, and other similar valves." October 8, 1888.

14547. William Parry, jun., and Richard Griffith, for "A new or improved automatic keyless lock." October 10, 1888.

14681. Joseph Tollerton, for "Improvements in fireproof curtains for the stages of theatres, and the like." October 12, 1888.

14724. Lawrence Wilson, for "Improvements in parquetry and other similar composite wood and artificial wood surfaces." October 13, 1888.

14755. Kate Caroline Howarth, for "An improved appliance for use in connection with the grates of domestic fireplaces." October 13, 1888.

15017. Frank Kendal, for "An improved electrical indicator

to show from which room or station a bell has been rung, in domestic electric bell and telephone circuits." October 19, 1888.

#### COMPLETE SPECIFICATIONS ACCEPTED.

Notice is hereby given, that all persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the date of the official *Journal*, give notice at the Patent Office in the prescribed form of such opposition.

17264. Thomas John Hancock, for "An automatic apparatus for the opening of lavatory doors and other such doors on prepayment." December 15, 1887.

266. Felix Tonnar and Wilhelm Schouren, for "Improvements relating to the ringing of church and other bells and to apparatus therefor." January 6, 1888.

494. James Hilton, for "An improved method of fireproofing mills or other buildings." January 12, 1888.

809. William Henry Tonks, of the firm of William Tonks & Sons, for "Improvements in latches or fastenings for doors, casements, skylights, fanlights, show-cases, and other like hinged or pivoted articles." January 18, 1888.

14709. William Horsfall, for "A new or improved construction for burning towns' and other refuse." October 13, 1888.

14750. Clement Waxin and Augustin Clery, for "An improved cement or artificial stone." October 13, 1888.

#### PATENTS SEALED, NOVEMBER 16, 1888.

12494. William Head, for "Improvements in apparatus for raising and lowering Venetian blinds." September 15, 1887.

13307. George Williamson, for "Improvements in apparatus for enabling the fastenings of turnstiles, doors, gates, barriers, or platforms to be released, and for the collecting the fee in connection therewith." October 1, 1887.

14851. James Coulter, for "Improvements in stone-dressing machinery." November 1, 1887.

14997. John Hanson, for "The treatment of alkali waste for use in the purification and deodorisation of sewage and impure waters or matters." November 3, 1887.

15065. Frederick Ransome, for "Improvements in the manufacture of cement." November 4, 1887.

TO INVENTORS.—Patents for Inventions, Trade-marks, and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & CASSELL, Patent Agents, 43 Southampton Buildings, Chancery Lane.

# The Architect.

## THE WEEK.

AN exhibition of the works of BARYE, the sculptor, will be held in the Ecole des Beaux-Arts, Paris, in the spring of 1889. It will be got up in order to obtain funds to pay for a memorial of BARYE, which is to be erected in Paris. Fine examples in "cire perdue" of the sculptor's statuettes will be lent with the water-colours and other drawings which served for studies of his works.

MR. C. D. E. FORTNUM, F.S.A., some time ago deposited his collection of works of art on loan in the Ashmolean Museum, Oxford. He has this week offered them to the University as a gift. The collection ranges from the classical period of Greek art to the period of the Renaissance; it contains many altogether unique objects, and, in the Italian series, is especially rich. Mr. FORTNUM's liberality will help to remove the incompleteness of the Ashmolean Museum, but we hope he has stipulated that fewer impediments will be offered to visitors who may desire to see his collection.

THE Committee of the South Wales Art Society and Sketching Club held a meeting at the club-room, Working Street, Cardiff, on Friday evening, under the presidency of Mr. EDWIN SEWARD, architect, the vice-chairman. The hon. sec., Mr. J. A. SANT, showed that the accounts of the recent art exhibition in the Public Hall, although not entirely closed, had a small balance in favour of the Society. This result was in great measure due to the kindly action of the Marquis of BUTE, the secretary reading a letter from Sir W. T. LEWIS, who, on learning of the efforts which had been made to insure the success of the exhibition, had kindly enclosed a cheque for fifteen guineas, also congratulating the Society on the work just accomplished. Reference was made to the fund which was being raised by the Society to assist Mr. W. GASCOMBE JOHN, one of the sculptor members, in his travels in Greece and Italy, and which is to be added to the corporation fund for that purpose. Mr. SEWARD stated that Lord WINDSOR had generously consented to head the Art Society's fund, and that he had just received a cheque for 10*l.* from his lordship. Mr. PARKER HAGARTY has consented to attend as a visitor-member at the meetings of the life-class held twice a week at the Society's room.

THE Exhibition of the Royal Society of British Artists is essentially a quiet one—quiet in colours, in subject, and in price. A great many pictures are purchasable at five guineas apiece. The large room is so subdued in appearance that a figure in a reddish-orange robe, *Rappaccini's Daughter*, becomes quite startling. But it must be said that if occasionally there are weak works, there is nothing pretentious. The Society is in a transition state, and allowance must therefore be made if the Exhibition is not equal to some which preceded it. Mr. WYKE BAYLISS, the president, is as scenic as ever in his pictures of architecture. Amiens Cathedral is seen with a procession passing through it; Lierre Cathedral and the Sacristy are as good as any of the painter's works. The President of the Royal Academy shows his friendliness by sending an exquisite profile of a blonde girl, which, although small in size, is a treasure; also some sketches from Rhodes, which are as characteristic as larger works, and a small sketch in blue and white of the *Daphnephoria*. Mr. GEORGE RICHMOND has a drawing of the Irish Secretary, who, evidently posed for the occasion, and appears to make eyes at the spectator. Mr. WATTS's *Ganymede*—a young child with a sad expression holding a cup and grapes—might readily pass for an "old master." Mr. DOBSON has one of his girls' heads with the title *On the Balcony*. Sir JOHN GILBERT's *Landscape Evening* is one of those bravura sketches which are familiar and seem repetitions. There are several pictures by the ordinary members which deserve to be noticed on another occasion.

THE vacancies in the French Academy of Fine Arts have been filled up. On Saturday last M. GUSTAVE MOREAU was elected as successor to the late GUSTAVE BOULANGER. The new academician is an artist who is a perpetual puzzle to the critics. Early works like the *Delivery of Athenians to the Minotaur* are plain to everybody, but afterwards M. GUSTAVE MOREAU appeared to take a suggestion from the English pre-Raphaelites. He looked at Classic scenes through Mediaevalism. He made his pictures most brilliant in colour because they seemed to be made up of an infinite number of spangles, and his figures had an air of mystery and mysticism that confounded the Parisian sightseer. His style may be called original, and it is certainly unique. The academicians did well to recognise the spirit of a man who could not fail to be misunderstood. GUSTAVE BOULANGER's professorship, which means headship of a national atelier, passes to M. BONNAT. He is best known as a portraitist, but he is a splendid draughtsman, and the student is to be pitied who enters his classes and is weak in his contours or washy in his colouring.

M. BLANCHARD, the engraver, who has been elected to succeed M. FRANÇOIS as a member of the Académie des Beaux-Arts, is known in England by his plates after Mr. FRITH's *Derby Day* and *Marriage of the Princess Royal*. He was born in 1819, and was a pupil of his father. Among his most popular engravings are *Christ the Consoler*, and *Faust and Marguerite* after ARY SCHEFFER, *The Repose in Egypt* after BOUCHOT, the *Smokers* and *Chess Players* after M. MEISSONIER. M. BLANCHARD obtained eighteen votes against fourteen for M. WALTNER.

MR. A. MARSHALL read a paper on "Old Carved Furniture and Woodwork" before the Leeds and Yorkshire Architectural Society. He remarked that an architect's duties were supposed to be confined to plans and designs for buildings, but he recognised that it was equally within the scope of the architectural profession to guide public taste as to the best style of furnishing and decoration. Alluding to chests, he said that they were of early origin, and were very important pieces of furniture with our ancestors. The early examples of the thirteenth century were somewhat rude, and had few pretensions to architectural beauty. In the fourteenth and fifteenth centuries they became more ornamental, and in some of our village churches there still existed some magnificent examples of chests of the fifteenth century. The lecturer then referred to wainscoting and panelling, and noticed different varieties of chairs, and the introduction of carved chairs into England. He described various types of cabinets, Court cupboards, tables, doors, fireplaces, and beds in use in the sixteenth and seventeenth centuries; and as to the adaptability of the old furniture to modern requirements, he said that in these practical times, when economy was one of the first considerations, no furniture was more capable of standing the wear and tear of our everyday business life than the quaint, stolid work of the seventeenth century.

THE French architects who expected to take part in a competition for the new Opéra Comique seem to be doomed to disappointment. We stated last week that an opponent to the competition was found in the Minister of Fine Arts, who backed a design made by one of his officials. A much stronger sort of opposition has arisen. On Saturday last the report of M. STEENACKERS, as chairman of the Special Commission on the project, demanding 30,000 francs for the expenses of the competition, came before the Parliamentary Budget Commission. The latter body declined to consider the application, on the ground that the duty of the Special Commission was confined to the approval or rejection of the official design, and did not comprise a right to apply for money. M. LOCKROY, the Minister, professed a desire to be rid of the affair, and the Budget Committee, therefore, while declining to recognise the demand, sent a query to the Chambers, to ask if granting the 30,000 francs would cause a deficiency in the Budget to that amount. It is like asking if the Chambers sit on the left side of the river. Of course the reply must be in the negative, and, unless some new dodge is discovered, there is an end to the competition.

### THE WORKS DEPARTMENT OF THE LONDON SCHOOL BOARD.

**A**MONG the legacies which were bequeathed by the members of the London School Board to their successors is a report on the defects of the Works Department. We suppose the new Board's right to that interesting document cannot be disputed, but many will say it would be turned to better account if it came into the possession of a different sort of legatees. If Lord HERSCHELL and his fellow Commissioners obtained the report, and were endowed with powers to utilise it—that is, of course, assuming that the charges could be brought home to particular persons—something more would be done towards promoting honesty in the government of the metropolis, especially as his lordship could hardly fail to transmit the report to the Director of Public Prosecutions, with a request that steps should be taken to enable certain shrewd people to obtain their deserts. If, finally, the report turned up in the Old Bailey, and was employed as evidence, the taxpayers of the metropolis might be excused if they appeared to be glad. If some became sceptical about the advantages of our system of local government nobody would blame them.

The report of the Commission on the Metropolitan Board of Works revealed that the members were ignorant of transactions which were in progress within a few feet of the rooms where they deliberated. A still worse state of affairs existed in the business of the London School Board. The relative value of the sums which were involved in the two departments cannot be stated, for nobody seems able to tell how much was added to the taxation through the way in which business was conducted in Spring Gardens and on the Embankment; but leaving money out of the case, there is no doubt that the practices in the School Board administration were more dangerous to the community. As we shall see, there was a sort of machinery for mischief which was absent from the transactions of the Metropolitan Board of Works, or at least from those of which we have knowledge.

The report with which we are about to deal comes from "the Special Committee on the Work of the Works Department," that was appointed in October 1887, "to report upon the whole of the existing arrangements relating to the work of the Works Department." To aid in obtaining information the services of Mr. EWAN CHRISTIAN and Mr. T. M. RICKMAN were secured. An inquiry by an independent committee, consisting of gentlemen who were not members of the School Board, would be preferable, especially as it was known that charges of dishonesty were to be raised. We suppose the School Board considered that an obligation rested on them to carry out their powers, and they were competent to punish or dismiss any officer who was found to be a culprit, and to bring an action at law against culprits who cheated, or permitted cheating, in contracts. But a committee, made up of members who knew that in less than a year their term of office was to expire, and who were not certain of re-election, could not forget that they might be held responsible afterwards for statements, and that their successors would hardly instruct the solicitors of the School Board to take up their defence. Hence we have a report about persons that is impersonal. The reader can come to any conclusion he pleases about the particular officer or contractor whose misdeeds are set forth, but it will be at his own risk. He cannot point to the report as his authority, or take it as a safeguard against confounding the innocent with the guilty.

Another reason for the silence about names was probably derived from the conviction of the committee that all the evils were the result of a system which was the Board's creation. Instead of giving commissions to several architects for schools, the Board set up an architectural department. We may give them credit for their efforts to secure economy and improvements in planning schools by that departure from an established procedure; but it was forgotten by the Board that there are limitations to departmental power. It was supposed that something infallible and omnipotent was sure to be created because the Board had a wish of that kind, and could form an official organisation. But where were the men to be found who

were endowed with more hands and eyes, with more productive brains than ordinary mortals, who could be ubiquitous and add hours to the days, for beings so endowed would alone be able to undertake the unparalleled task of the London School Board? It is now found that the expectations of the creators of the architectural department are not to be realised, and the report of the Special Committee might be considered as a wail over its failure.

As a rule, all branches of a public office in this country uphold each other, and it may therefore be well if we give some instances to suggest the relations between the School Board and the officials, which were certainly of a peculiarly independent kind. We may premise that the committee admit that in every one of the alleged cases of defective building which were investigated, "some defects and omissions which ought not to have been passed have been found to exist." What is the first reason offered for so discreditable a state of affairs? It is the following:—"The resolutions of the Works Committee, regulating the procedure in reference to school buildings, have been practically inoperative, and have been allowed to fall into abeyance"! Some examples of the disregard of the Board's regulations are mentioned. It was ordered that every clerk of works should keep a diary, in which, among other information, were to be kept an account of daywork in connection with extras and measurements of extra foundations; the diary was to be returned to the architect on the completion of the work, and to become the property of the Board. To what extent was so prudent an arrangement carried out? The committee say they have ascertained "that these regulations fell almost immediately into practical abeyance." There was a special inspector appointed who was to keep the clerks of works up to their duties, and who was himself under an obligation to send in fortnightly reports on all the schools he visited. But, as far as the committee are aware, the reporting inspector's reports were never made, and, indeed, the investigation was "embarrassed by the absence of many of the original documents relating to the construction of the schools which ought to be in the possession of the Board." With such a supervision and so much negligence about records, the committee say it is not surprising that abuses crept into the execution of the works, but, apparently, there was no necessity to creep. Meanwhile the Works Committee, like good, easy men, "were acting under the impression that their resolutions were being strictly observed, and upon no occasion does it appear that their attention was called to the non-performance of those duties." But in business which involved so much expenditure the Board might surely be regardless of a circumlocutory etiquette, and take the initiative. A few questions would have saved thousands of pounds.

A builder who intends to act dishonestly will, of course, try to omit much of his work in foundations. The School Board appear to have had a misgiving that they were cheated in that way, for in January 1879 there is a record "that the architect undertook to be present himself in future when the foundations were dug out, to see all 'bottoms.'" But the committee having discovered that where the questionable foundations could be examined, they were either not carried down to the depth that was paid for, or that the concrete rested on an insecure "bottom," or was not of the required thickness, and having also ascertained that no evidence is forthcoming of the architect having informed the Works Committee of his inability to see the "bottoms" himself, the Special Committee express their difficulty to understand the state of the foundations, unless on the assumption "of collusion or fraud on the part of some of the persons concerned, which the architect did not discover."

It is also stated that instructions for alterations were given by the architect or the inspector of clerks of works, who appears to have assumed the powers of the architect, and, in many cases, no proper order was given until after the work had been put in hand or finished. The report adds, "Of these things, also, the Works Committee do not appear to have been informed. The Special Committee believe that the serious irregularities to which they have called attention, and from which the Board have suffered loss, are mainly traceable to the manner in which the resolutions of the Works Committee were practically violated by those who ought to observe them, or ought, if they found it impossible

to have observed them, to have reported the fact to the Works Committee."

The Board must take the responsibility for the organisation of the architectural department and its shortcomings, as it would be absurd to expect the officers to do more than is practicable elsewhere. When, for instance, it is said "that there were not a sufficient number of clerks of the works employed to efficiently superintend the erection of new buildings," the deficiency was solely a Board's or Finance Committee's question. What is the use of an architectural department if it cannot be conducted cheaply, and there is generally a tendency in architecture to have a special standard for the expense? The search after economy at all hazards is seen in the history of the official measurer. It was believed that one man could measure up all additions, variations, and omissions of contracts, settle final accounts, furnish estimates for all provisional amounts demanded, and other work of quantity surveyors for the sum of 300*l.* a year. It was afterwards discovered that one man could not do surveyors' work for so many schools as were then in progress, and the old arrangements had to be renewed. It was also necessary to prepare plans of schools with an expedition that was without precedent. When therefore it is reported that sometimes quantities for a new school had to be taken out before the plans were completed, with the aid of plans of a similar school, and also that a serious proportion of a tender was for provisional quantities and amounts, all that laxity was due to the circumstances of the time, although another cause may now be ascribed. The head of an office is bound to recognise economy, and when it is charged that there is no evidence of measures being proposed to remedy the imperfect supervision and the undue pressure of work, it would be absurd to suppose that the omission is due to negligence. No man would abstain from getting help if he knew it could be obtained.

The weakness of the architectural department could not, however, be concealed, and unfortunately men were to be found who were ready to take advantage of it. The Investigating Committee now lay down the maxim that "the best security for good work is to be found in the employment of good builders," which seems like a repetition of advice that was given by Mr. CHRISTIAN or Mr. RICKMAN. But the Board's conditions were not always attractive to the good builders, even if men of that class got a chance. The course adopted up to 1883 for the discovery of builders was not revealed to the Investigating Committee. The report says "there is no evidence which shows upon what principle or by whom these selections were authoritatively made." When the system of open competition was introduced it was not to be believed that all the defects of the former way of dealing with builders were removed, and the committee have to acknowledge that the effort which was made to secure a higher class of contractors turned out a failure. It is also admitted that there were "circumstances" in the Board's system which could be turned to account by builders if they were "deficient alike in experience of sound work, in the requisite capital, and legitimate habits of business." The circumstances were the absence of efficient supervision, the disproportion of the sum which was withheld as retention-money, the elasticity of conditions of contract. In other words, the arrangements of the architectural department should have been very different in character.

With an insufficiency of clerks of works, it was no doubt believed that there must be a check against bad work by keeping back 20 per cent. of the contract amount for six months after the completion of the contract. In practice the action was made more endurable, but builders with capital hesitated about accepting contracts which made them liable to so large a retention. Men who traded with capital that was not their own were less timorous, and, as they also obtained materials on credit, they could not insist on getting the same quality as was obtainable by builders who were able to pay on delivery. It seems hardly credible, but the report states that the standard of quality as defined in the specification was allowed to be departed from and something else substituted, on the assumption "that it was as good as the Board could get for the money." A theory of that kind would be taken as an invitation to deviate from the contract deed, and who can wonder when he reads the

committee's statement that "it is certain that both from imperfect material and imperfect workmanship the Board have suffered serious loss"? It is considered probable that the builders when tendering reckoned upon variations of the conditions of contract to a considerable extent, but it is now difficult to know how far the reckonings were correct. All the committee can say is that in many schools the amount of repairs is already "abnormally large," and there is, moreover, a possibility of the expenditure for repairs becoming a very serious item in the future.

Some people may ask if there is not a remedy against the builders for their defects and omissions, the latter meaning work that was paid for but never executed. If there were no limitations of time, it would be waste of money to undertake an action to recover either the payments that are not to be accounted for, or damages for the inconvenience caused by defective work. The reason is that the usual practice was departed from both within doors and with out. According to the report, "detailed accounts do not appear at any time to have been presented to the Works Committee"; their substitutes were abstracts which were practically worthless as means of investigation of the outlay. The Works Committee passed the documents, which represented so much money, "as a matter of routine," and the Finance Committee paid the money also as a matter of routine. All the Investigating Committee can now say for the consolation of the inhabitants of the metropolis is "that it is very doubtful whether the Board can recover from the builder any loss to which they may have been subjected, either from improper charges in the settlement of the accounts, or from any species of neglect in the execution of the work." It is also charged that accounts were sometimes prepared in a way that would largely increase the commission of the quantity surveyor, but in cases of that kind we suppose there is also no use in invoking the aid of the law.

The Board can, however, adopt a course which, if it cannot make up some of the losses, will at least prevent honest men from being made to suffer from prejudice. The course we recommend is the publication of the names of the officials and builders who are in any way connected with the irregularities and discrepancies, or what Mr. RICKMAN describes as "defects and omissions which ought not to have passed, and which are not allowed for in accounts." It is difficult after reading the report to believe that any of the builders who obtained a contract from the School Board could be honest, for although certain schools are mentioned, no one can suppose that the irregularities were confined to them. Now, we cannot believe that all the builders conducted their work without any regard for honesty, and even among those who were not large capitalists there must have been some who were above temptation. Yet they are likely to suffer because they were builders to the Board. The same grievance falls on the quantity surveyors and other members of the staff, who performed their duty in a rightful way. Indeed, the public may draw a conclusion from the report that nobody who takes a part in the designing, measuring, or inspecting of buildings is to be trusted, and on that account we must press for further action by the new School Board. Silence is often golden; but the world is not to be reformed if men who act wrongly are treated as if they resemble unknown quantities. The School Board should also give a chance to the officials to offer explanations about the charges which are raised against them. Credit is given to the Works Committee for their direction, which brought about improvements in planning and designing schools; but if they take the praise, the committee should take the blame for what looks like an indifference to duties which were laborious.

If the Board will be contented with allowing the report to remain in its present state, there is nothing to prevent the builders from taking action, if they consider that the statements will in any way cause architects and the public to believe that connection with the Board schools is not a guarantee of fair dealing. The metropolitan builders and their societies should try to obtain more definiteness in the statements, or at least an acknowledgment that builders who may claim that they were faithful to specifications and conditions are not mixed up with the allegations.

## ART AS A PROFESSION.

AN address was delivered by Mr. John Lovell before he distributed the prizes to the students of the Liverpool School of Art. Mr. Lovell said that as a journalist who had had some little experience on the outskirts of a kindred art—literature—he might perhaps be able to say a few words that would not be considered entirely out of place concerning the spirit and temper in which an art career should be undertaken; and as one whose business it had been for more years than he cared to count up to observe closely what went on in the great world around him, he might also be able to say something to the purpose concerning the prospect which opened itself out to those who were about to adopt art as their profession in life. The first of these subjects—the spirit and temper in which an art career should be undertaken—was one which might be viewed from two different standpoints: that of the artist in relation to his work, and that of the artist in relation to the public, to whom he must look for recognition and support. Let them, to begin with, take the standpoint of the artist in relation to his work. There was, he supposed, no dictum of the ancients which had been more universally or more frequently quoted than that in which Horace, in his “Art of Poetry,” says that the poet is born, not made; and he was afraid he must add that there was probably no dictum of any great writer of any age which—quite contrary to the meaning and intention of its author—had done more mischief in the world of art. It had been interpreted too literally. It had been too widely applied. Not merely in poetry, but in all the arts it had been made the excuse for a reliance upon gifts and a neglect of cultivation which had strewn the shores of human achievement with the wreckage of great minds that might otherwise, with the help of industry and perseverance, have been brought fully-freighted into port. That the artist must be born—that, in other words, he must be endowed by nature with the special faculties that fit him for his high calling—was most true; and in that sense the artist could not be made, for unless the special faculties are there to begin with no amount of cultivation would produce them. But to say that, given the existence of the special faculties, no after process of making was required was so obviously untrue that nobody in his senses was likely to be deceived by it. Unfortunately, however, the proposition very rarely presented itself in this naked and repellent form. It came in its most insidious guise when it whispered into the charmed ear of an exceptionally clever student that, inasmuch as he was more highly gifted than the majority of his fellow-students, and could do with ease what they could only do with difficulty, there was not the same need for him as for them to plod and strive and weary himself with the drudgery of persistent training and discipline. When it was so applied, the Horatian dictum became one of those half-truths which, according to a modern poet, were “ever the blackest of lies.” The whole truth was not only that the born artist must be afterwards made, but that the richer the quality and the finer the texture of his mind, the more intricate and delicate would be the necessary process of making. And they might depend upon it that no more ruinous heresy could lay hold upon the mind of the art student than that which told him that gifts were in any degree a substitute for labour. And by cultivation he did not merely mean training in the technique of the art one had chosen to follow; nor study, however diligent, of the methods of the greatest masters in that art; nor even the drinking in of great fresh draughts from the fountain head of nature herself. These were all means of the first importance in reaching forward towards perfection, and might on no account be neglected. But the cultivation he meant included more than this, and took a wider range. It was that cultivation which sought to expand and fertilise the mind, not in one direction only, but as a whole—that cultivation which, recognising the sisterhood of all the arts and their helpfulness to each other, sought to lay as many of them as possible under contribution for the benefit of the one to be enriched. It was by the gathering together of ideas from every available source, by the correlation of those ideas, and by the contact which takes place among them during the process, that new ideas were engendered, and men became original. Other things being equal, it was always out of the fullest mind that the best art work came. And this was why the labour of the artist should ever be in proportion to his gifts; for the more far reaching and comprehensive the grasp, the larger was the quantity, the greater the variety, and the finer was the quality of the materials which it demanded for its purpose. Turning to the second standpoint from which he proposed to view the spirit and temper in which an art career should be undertaken—that of the artist in relation to the public, to whom he must look for recognition and support—the lecturer said that to begin with he thought he was correct in saying that every exceptional gift carried with it a corresponding weakness, and was beset by its own special form of temptation. Now, it seemed to him that the vulnerable

spot—if there be one—in the highly-strung artistic temperament was its extreme sensitiveness, and unless this spot was plated over with thick armour the young artist stood in some danger of being wounded to the death by the very breath of public opinion, on which he should live. It was no doubt calculated to demoralise the strongest artistic mind to find that the subtle beauties and the more recondite excellences of the work which is produced, were by ordinary people ignored or misunderstood. Certain it was that for an artist to allow himself to be chafed and fretted by the vagaries of a not duly appreciative public was to play straight into the hands of that which he had ventured to call the besetting temptation of the artistic temperament. That temptation, as it seemed to him, ran in the direction not so much of overrating the faculties to which they were indebted for a sense of the beautiful, as in underrating the faculties upon which they had to depend for their supplies of the useful. That way of thinking, indulged in to excess, generally ended in making him a member of some little clique of mutual admirationists, or in relegating him to the wilds of Bohemia. But there was no need to carry consequences out to this extreme limit. The mischief began earlier. To cultivate a habit of regarding that which he would call the practical business intellect of the world, as being necessarily inferior to the intellect that was capable of devoting itself to art, was to set up antipathies between the artist and his public which could not but have the effect of driving further and further apart those who in their own best interests should ever be striving to bring themselves into closer contact. A far healthier outlook upon life for the art student was to regard each type of mind as having its appointed place in the human economy, and as being specially equipped by an equal hand for the particular kind of work which fell to its lot. Or—which was better still—let him apply to the rest of mankind a standard which he would do well to apply to himself, namely, that of judging men not by the aptitudes which were bestowed upon them by nature, and for which, therefore, they were neither subject to censure nor entitled to applause, but by the measure in which they utilised those aptitudes for the common welfare. He would then have established a bond of sympathy between himself and his public which would protect him from his own special forms of weakness and temptation, and make him a better, a happier, and a more prosperous man. And now he (the lecturer) would ask what were the rewards of a career which at its outset and all along its course demanded so much patient labour, and was beset with so many difficulties? Or, rather, what was the prospect which opened itself out to those who were about to adopt art as their profession in life? He did not deny that the commercial and industrial circumstances of the past few years had had the effect of restricting the gains and diminishing the fortunes of the class upon which in the past artists have mainly depended for support. Nor did he deny that painters who had insisted upon adhering to the old ways had severely suffered in pocket thereby. But he certainly did deny that the one misfortune was the necessary consequence of the other; and he ventured to affirm that, for the painter who was able to read the signs of the times, and was willing to adapt himself to the changes which were going on in our midst, there never was a brighter outlook or one more full of promise than there was at the present moment. They must briefly consider, then, what was the nature of these changes, upon which so much depended. First, it was one of the peculiarities which distinguished the present from all former periods of depression in trade, that the same causes which had led to a decrease in the wealth of the rich had brought about an increase in the wealth of men of moderate and even of small means. Secondly, side by side with this remarkable transfer of wealth from a smaller to a larger section of the community, education had, by multitudinous agencies, been dipping deeper and deeper, and spreading more and more widely among the lower strata of the population. Thirdly, there were none of those educational agencies which had displayed greater activity or shown more palpable results than the Government schools of art, of which that was one. Lastly, the methods by which works of art were reproduced and multiplied, had increased a thousandfold. Now, what must be the necessary result of all these changes from an art point of view? Was it not that where the patronage of the few had broken down, the many had come to the rescue? Was it not that where the painter failed to find a purchaser in his old market, he could turn to the new market, and find not only an equally liberal patron, but an infinitely wider field of fame? He granted that for the painter who would not allow his work to be translated into black and white there was a very poor outlook indeed; but for him who chose to avail himself of the reproductive processes of the day there never was a better prospect. Time was when art, held at arm's length by the industries which ministered to the comforts as distinguished from the luxuries of life, could scarcely find an entrance to the homes of the people. Now she took her stand in almost every workshop, and brightened by her presence the humblest home in the land. In no department of our industrial activities, perhaps, were the results of this enormous change more visible

than they were in that which connected itself with the printing press; nor was there any time of the year in which those results were brought out so prominently as they were at the present season. It was not for him to enlarge upon the beauty and variety of the innumerable works of art which as Christmas came round were scattered broadcast throughout the country. His purpose was to point out that behind every illustrated gift book, behind every presentation plate, behind every Christmas card, there stood an artist. That being so, he would ask those present, in conclusion, to adequately realise this stupendously significant fact—that the patronage of art was no longer the exclusive prerogative of the upper ten thousand, but had passed to the nation—aye, to the empire at large. They would then be able to clearly foresee that as years rolled on, and as education dipped deeper and spread more widely, and as fresh relays of students continually went forth from these schools of art to lift the multitude into a higher region of appreciation and delight, an ever-broadening prospect of remuneration and fame opened itself out to those who adopted art as their profession in life.

### ART AND CULTURE.

IN the course of an address which he delivered in Leeds last week, Sir John Lubbock said:—

It is not only in the East that great works, really due to study and labour, are attributed to magic. This is as true of art as of science. "When we read the lives of the eminent painters," says Sir Joshua Reynolds, "every page informs us that no part of their time was spent in dissipation. Even an increase of fame served only to augment their industry. The pictures thus wrought with such pains now appear like the effect of enchantment, and as if some mighty genius had struck them off at a blow." Nothing, in fact, is denied to well-directed labour; nothing is to be obtained without it. But alluding to this in a subsequent discourse, he adds, "The industry which I principally recommended is not the industry of the hands, but of the mind." Science and art are sisters. The mission of art is in some respects like that of woman. It is not hers so much to do the hard toil and moil of the world as to surround it with a halo of beauty; to convert work into pleasure. In science we naturally expect progress, but in art the case is not so clear; and yet Sir Joshua Reynolds did not hesitate to express his conviction that "so much will painting improve that the best we can now achieve will appear like the work of children." The appreciation of nature, which characterises the present century, the intense love of scenery, to which we owe so much, which not only adds so much to the happiness, but even, I venture to think, to the purity of life, we owe in no small degree to art. May we not hope in this respect also still further progress may be made; that beauties may be revealed, and pleasures may be in store for those who come after us, which we cannot appreciate, or at least can but faintly feel? And yet even in art the appreciation of landscape is but recent. It is remarkable that while artists have long recognised the necessity of studying anatomy, and there has been from the commencement a professor of anatomy in the Royal Academy, it is only of late years that any knowledge of botany or geology has been considered desirable, and even now their importance is by no means generally recognised. I have, of course, no pretension to speak of art, but even in the case of the greatest masters before Turner, the landscapes seem singularly inferior to the figures. Sir Joshua Reynolds tells us that Gainsborough framed a kind of model of a landscape on his table, composed of broken stones, dried herbs, and pieces of looking-glass, which he magnified and improved into rocks, trees, and water, and Sir Joshua solemnly discusses the wisdom of such a proceeding. "How far it may be useful in giving hints," he says, "the professors of landscape can best determine," but he does not recommend it, and is disposed to think, on the whole, the practice may be more likely to do harm than good. In the picture of *Ceyx and Alycone*, by Wilson, of whom Cunningham said that with Gainsborough he laid the foundation of our school of landscape, the castle is said to have been painted from a pot of porter, and the rock from a Stilton cheese. There is, indeed, another version of the story—that the picture was sold for a pot of porter and a cheese, which, however, does not give a higher idea of the appreciation of the art of landscape at that date. This want of appreciation of the beauty of scenery is also apparent in literature. Ancient literature contains few references to scenery. Mountains are referred to only as objects of horror, and there are so few mentions of colour, either, for instance, of sea or sky, that some have even been led to imagine that the ancients must have been colour-blind, or at any rate incapable of seeing the certain colours as we do now. Our minds might have been constituted exactly as they are, we might have been capable of comprehending the highest and sublimest truths, and yet but for a small organ in the head and the world of sound would have been shut out from us—we should lose the sounds of nature, the charms of

music, the conversation of friends, and have been condemned to perpetual silence; and yet a slight alteration in the retina, no thicker than a sheet of paper, no larger than a finger-nail, and we should lose the glorious spectacle of this beautiful world, the exquisite variety of form, the play of colour, the variety of scenery, of woods and fields and lakes and hills, seas and mountains, the glory of the sky alike by day and night. Art has the power of bringing together the most beautiful scenes from distances both of time and space. They not only endow us with wings, which may transport us without effort, suffering, or loss of time on our part from our own country to the most distant regions of the globe, and bring before us, one after another, London, Rome, Athens, Constantinople, Cairo, Benares, Peking, or Yokohama; the ocean in all its varied moods, the fields and woods and rivers of England, the lakes and mountains and glaciers of Switzerland, the prairies of America, the deserts of Africa and Arabia, the snows of winter and the sunshine of summer; but they can transport us back through centuries in a moment, and bring vividly before us the greatest personages and most interesting scenes and events in history.

### TESSERÆ.

#### The Roman Cavaedium and Peristylum.

W. RAMSAY.

AS houses became more spacious and the dimensions of the atrium were increased, it became necessary to support the roof with pillars, one being placed at each corner of the impluvium. In process of time a room was found to possess many advantages in point of coolness and ventilation in which the aperture was made larger than was absolutely required for the admission of light; more pillars were in this case required for the support of the beams, and a small open court was then formed below the impluvium, surrounded by a colonnade. An apartment formed upon this plan was termed a cavaedium. When the size of this court was considerably enlarged, so as to leave merely covered cloisters between the pillars of the colonnade and the walls, the court and cloisters were termed peristylum. Houses on a great scale had an atrium, a cavaedium, and a peristylum, all spacious, but occasionally the atrium was contracted to a mere ante-chamber, and the cavaedium became the great reception hall. When this was the case, the atrium was sometimes roofed over completely (*atrium testudinatum*), receiving light from the cavaedium on one side and from the outer door on the other. It is clear that it must have been difficult to determine the exact point at which an atrium passed into a cavaedium, and a cavaedium into a peristylum, and it is not surprising that the expressions employed by ancient writers on these matters should be occasionally ambiguous. It is quite unnecessary to enter upon the details of the controversy maintained by those upon the one hand who maintain that atrium and cavaedium are absolutely synonymous, or at all events, that the cavaedium was merely the small court in the centre of the atrium, and by those who insist that these words always represent apartment entirely distinct. It is enough to bear in mind that the atrium was never dispensed with, that neither the cavaedium nor the peristylum was essential, and that when we find one only in may be difficult to determine to which of the classes it properly belongs.

#### Destruction of Roman Temples.

C. MERIVALE.

It is impossible but that, in the decline of Paganism, these sacred buildings must have suffered from neglect, even before the churches of Christianity rose to supplant them. Neither Constantine nor his immediate successor ventured to close them. Theodosius, who destroyed the temples at Alexandria, still spared those of the Pagan metropolis. But the violence of the Christians grew with their strength. In 399 the edict of Honorius suspended all the temple services; and the clause which forbade any outrages to be committed on the buildings themselves seems to show not only that such were to be apprehended, but that they had been already offered. Augustine boasts in one place that all the statues in Roman temples had been demolished; but he speaks elsewhere of temples and sacred groves being appropriated to Christian worship, and sanctified thereby; and we must suspect Jerome of his usual exaggeration where he exults in the general ruin which, as he asserts, had fallen upon the sacred places of the heathen. At all events, there is no more brilliant description of the Pagan shrines of Rome than that of Claudian, himself a Pagan, at the very epoch to which we are now referring. At last, in 426, the younger Theodosius issued an edict for their destruction, and this edict is generally supposed to have been carried out pretty completely. It is said that from this era we meet with no reference to the temples in the imperial legislation; but this, indeed, was hardly to have been expected when the temples

had ceased to be public property or objects of public interest. It is not strictly that from henceforth there is no mention of them in the narrative of political events. Procopius, in the sixth century, alludes to the Temple of Peace as then existing, with other similar monuments, and particularly describes the form, the dimensions, and the material of the Temple of Janus. The populace, he says, Christians though they nominally were, attempted to open the gates of this temple as a protection against an advancing enemy; a trait of superstition which shows that they still retained a lurking respect for the ideas of antiquity, and would have revolted against any indiscriminate attack upon their monuments and emblems. If, however, these venerable edifices escaped a general proscription and demolition, they fell for the most part by a more lingering process, being despoiled from time to time by the cupidity or caprice of the private owners into whose hands they came. Thus, in the reign of Justinian, a Roman matron, the proprietor of a ruined temple on the Quirinal, presented eight of its columns to the emperor for the decoration of St. Sophia. Vast numbers of columns, friezes, and entablatures were thus transferred to Christian churches. The application of the temples themselves to ecclesiastical uses was more rare, and is believed to have begun rather later. The Pantheon had escaped destruction or serious mutilation down to the seventeenth century; it was converted into a church in the year 604, in which year the gilded tiles of the temple of Venus and Roma were also transferred to the roof of St. Peter's basilica. We know, however, of four or five only of the ancient temples which were equally fortunate with the Pantheon; those, namely, which were dedicated to SS. Cosmas and Damianus, to St. Stephen, St. Hadrian, and that of Vesta or Romulus, which has assumed the name of St. Theodore. On the other hand, we read of not less than fifty-six churches erected on the sites of temples either previously destroyed or actually pulled down for the purpose.

#### Contrast of Colours in Nature.

W. BARNES.

Nature is very sparing of showy contrasts of warm and cold colours. Red and blue are very rare, and of yellow and blue the cases are but few, and black and blue are found in lepidoptera more often than white and blue are seen in our flora or fauna. It is not uncommon for one of two strong colours to be overcast with a tinge of its fellow, or for both of them to be reconciled by a common touch of black, or of some third colour, or of one of them to be lightened by a dash of white, while the other is lowered by as much black, and so red, offhued with black—russet and green upbrightened with white—often meet in the autumn in dead and dying patches of fading leaves. It may be shown, I believe, by the refractions of light in crystallised gypsum that brown is the complementary colour to lavender-grey; and how true to herself is nature, we may go forth and see, in the fall of year, in the dead and curled leaves of the mugwort, or meadow sweet, which are beautiful even in their death, with one side brown, and the other the brown-matching grey; and, if brambles be cut in the leaf-green season, their two surfaces soon wither into the harmony of grey and brown. And what use are we to make of these hues of nature? They are warrants for a grey mantle under locks of brown hair, or a brown bonnet or trimmings, or a grey room wall with brown furniture; and if, in a hot summer's day, I see the dark leaf-shades playing on the grey bark of a young beech, I can boldly lay darkish leaf shapes on a wall of the beech-bark's hue; or if, after the winter rains, I find a barkless pole in railings, tinted with the palest blue-grey, and on breaking off a splinter of it I find its inner wood of its true colour of pale brown-yellow, why should I not take the inner tint for my wall and the outer one for the skirting? Or, if I pick up a piece of lichen of dull green on one side and dull grey on the other, why should I not bind my book in one colour and lay on it a lettering-piece of the other? Nature is the best school of art, and of schools of art among men those are the best that are nature's best interpreters.

#### The Quattrocentisti.

M. GRUYER.

The Italians have furnished us with the word *quattrocentisti*, which is now commonly employed in the language of the arts, and we ought, therefore, to realise what it means. Literally the *quattrocentisti* were the artists who lived between the years 1400 and 1500, or in other words the artists of the fifteenth century. If so rigorous an explanation is demanded the word is without sense. If we call all the artists who were born before 1500 *quattrocentisti*, then Leonardo da Vinci, Michel Angelo, Titian, Raphael, Andrea del Sarto and Correggio are *quattrocentisti* equally with Luca Signorelli, Sandro Botticelli, Domenico Ghirlandajo, Filippino Lippi, the Bellini and Mantegna. The confusion thus becomes evident, and we must conclude that the word *quattrocentisti* should not be employed if it must be subordinated to dates. What it

expresses is an idea without any definite relation to time. The *quattrocentisti* are the artists of the fifteenth century, in whose works something primitive is conserved. Filippino Lippi, who was born in 1457, is a *quattrocentista*, whilst Leonardo da Vinci, who was born five years earlier, in 1452, is not one. The *quattrocentisti* are the representatives of a state of art which, although no longer in infancy, is yet in a condition of dependence, and therefore tied down. As for those men of genius who belong to the fifteenth century, but who were strong enough to soar above their age, to wing their way to new horizons and to penetrate into worlds which were supposed to be inaccessible, no matter in what time they were born, or when their works were produced, they cannot be called *quattrocentisti*. Leonardo da Vinci, Michel Angelo, Titian, Raphael, Andrea del Sarto, Correggio, are beyond classification; they are not of an age, but belong to humanity in general.

#### Gibbs as an Architect.

J. ELMES.

Gibbs was an architect of the school of Wren, but effected by laborious detail and superabundance of ornament—as may be seen in his works, particularly in the interior of the church of St. Martin—what Wren accomplished by more simple and scientific means. The exterior of St. Mary-le-Strand is of two Orders in height, which presupposes two storeys to the interior—a fault committed by Jones in his banqueting-house, Whitehall, and by Wren in his St. Paul's Cathedral. The former has for an apology that his building was part and parcel of an enormous palace, and corresponded with such portions of it that had two storeys, and this required the omission of one for height in the interior. For Wren it may be said that his two storeys of coupled columns in the western front have nearly the same proportions of one, and that viewing his cathedral from a distance—the best position for seeing its beauties—the lower is entirely concealed from view by the houses that surround it. The circular portico in the western front of Gibbs's church in the Strand is a palpable and clumsy imitation of Wren's beautiful semi-rotunda to the north and south transepts of St. Paul's. The summit of its cupola was to have been surmounted by a farthingaled statue of Queen Anne. The exterior of St. Martin-in-the-Fields is in a bolder style and purer taste. The columns *in antis*, or, to speak less technically, the columns between the antæ or pilasters, that form the retrocessed porticoes of the north and south aisles, are both novel and effective; and the Corinthian hexastyle portico of the western end would be unexceptionable, were it not for the cumbrous steeple that bears down its apex. No such monstrosity disfigures any of Wren's churches, whose steeples always rise from external and visible towers. The interior looks fine from a redundancy of ornament—divested of which it would degenerate into commonplace. It is, however, a large and commodious edifice, well adapted to the parochial church service of the Establishment, the arrangement of which Chambers did not disdain to imitate in his German Lutheran church in the Savoy, near Waterloo Bridge. Of Gibbs's other work, the Radcliffe Library, Oxford, it can only be called a practical blunder; for devoid of the necessary scientific skill in construction that is requisite to complete the character of an architect, he intended to have executed the cupola with stone, but it would not stand: it was obliged, therefore, to be taken down and to be built of lath and plaster. Gibbs published a treatise on the "Elements of Architecture," which possesses nothing new, and is to be considered more as a student's guide to drawing the five Orders of Italian architecture according to that master's proportions—which are not sufficiently correct to be considered as models—than a treatise on the art of which he aspires to be a teacher.

#### Bronze of the Ancients.

R. WESTMACOTT.

That composition which was so extensively used by the ancients for statues—called by the Greeks "*chalcos*," the Romans "*æs*," and the moderns "*bronze*," from the Italian *bronzo*—is a mixture of copper and tin, with sometimes small portions of other metals. The composition of this material, so extensively used by the artists of antiquity, appears to have been a subject of great care. There were rival schools for its preparation. Pliny especially records those of Ægina and Delos, and says the highest honour was given to that of Delos and the next to the Æginetan bronze. The mere list of names of the different kinds of bronze known to and used by the ancients is curious. Pliny says there was rivalry between two of the greatest sculptors of the best period of the art in the material each employed. Myron used the bronze of Delos, Polyclethus that of Ægina. Besides the bronzes of Delos and Ægina there was the Corinthian; that of Tartessus; then another kind, called the "*æs Demonesium*"; also the "*æs nigrum*" (black), and the "*æs candidum*," or light-coloured, supposed to have had silver in it. There was also a bronze of a liver colour, called "*æs Hepatizon*," which probably resembled the brown or true bronze colour of the cinque-cento works.

There were other modes of working in metal besides casting used by the ancients. Such was the solid and the hollow hammerwork (*sphurelaton*) described by Pliny and others. The earliest metalworks were doubtless produced in this way. There were various modes of exercising this art. Pausanias saw several works of the kind, and explains the different processes. Pliny also furnishes some very curious information upon the subject. Either solid pieces of metal were beaten into shape and fastened together by means of pins or keys; or the metal was beaten out into plates, and then worked into the desired form over a core or nucleus of wood. A small head of *Osiris* in the British Museum exhibits an instance of this practice. The form is bronze, and the centre, of wood, is still remaining. Of entirely solid statues, Pliny mentions an interesting example in the statue of *Diana Anaitis*. Other instances might be quoted, but the above are sufficient to prove the practice. Ancient authors allude to some very remarkable effects produced by the mixture or fusion of metals, by which the complexion of the countenance could be given. Callistratus speaks of a bronze statue of *Cupid*, by Praxiteles, on the countenance of which was a vivid blush. He mentions another, by Lysippus, in which the cheeks were coloured like a rose. Pliny refers to a statue of *Athamas*, sitting overcome with remorse after the murder of his son, and says that the artist, in order to express the effect of shame, had mixed iron with the bronze, which caused, "by its redness shining through the bronze," the appearance of a blush. Pliny does not say he saw this work himself. Plutarch, again, refers to a statue, made by Silanio, of *Jocasta Dying*, and tells us that by a peculiar mixture of the metals used, a cast of paleness was given to the complexion. Too much dependence must not be placed upon these general statements. That the works above referred to, and others that might be mentioned, exhibited colour is likely enough, but that those tints were produced in the way suggested, namely, by the fusion of metals, is next to impossible.

#### The Cathedral of Treves.

SIR F. PALGRAVE.

No one of the Christian Basilicæ at Rome resulted from any adaptation of the civil structures of heathenism to religious purposes. The columns fell, to rise in new localities. Rome furnishes no example of a basilica preserved by its application to Christian worship. No confirmation is given in the ancient capital to the orator's assertions, exulting, in the presence of Gratian, at the crowds which filled the ancient halls of justice, then, as he boasts, resounding with hymn and praise; yet we can point out one city in which his assertions are not a rhetorical phrase, but a truth. Do we seek for the verification of the words of the poet-rhetor—"Basilica, olim negotiis plena, nunc votis pro tua salute susceptis"? At Treves we find that which at Rome we search for in vain. Here alone can we behold the one example of a basilica consecrated as a Christian church, in which you enter, and see the Corinthian capitals displaying their graceful foliage, mutilated and yet distinct, through the rude wall which encircles them, whilst the shaft of another, displaced and broken, lies in gigantic bulk before the portal of the edifice. This, indeed, is the very city in which the poet-rhetor was speaking—for he is Ausonius, and the city is Treves. The ancient capital of the Roman Empire beyond the Alps furnished the model for the structures, which, far more than Rome herself, assisted in the development of Christian architecture. It is indeed a strange fate of Treves, that this secluded city, on the banks of the Moselle, should have been so singularly influential in the destiny of Christianity. Hence proceeded the tribes who, after their long and devious migrations, reached their seat in Asia, where, as Galatians, they were addressed by the Apostle: preserving, even as late as the time of St. Jerome, their institutions, their laws, their language. In such a connection of race—such a continuance of language—such an adherence to national institutions, thus uniting the Galli of Asia with their ancient kinsmen—do we not discover some of the causes which facilitated the very early and very rapid diffusion of Christianity in Gaul? Treves appears as a link between the churches of Polycarp and of Irenæus. Other circumstances exalted her importance in the annals of the Church. At Treves Jerome studied and commented upon the Holy Scripture; at Treves Ambrose was born, amongst the greatest, both by his life and in his teaching, of the Fathers of the West; and this character, which events bestowed upon Augusta Trevirorum, must have greatly enhanced her influence in all matters connected with the Church, and rendered her example more prominent, her testimony more weighty, her precedent more commanding. Three several reconstructions have greatly obscured the vestiges of the Roman basilica which the Empress Helen converted into the present Dom of Treves. That its original scheme was identical with the Basilica of Maxentius at Rome, a vaulted hall supported by piers, is still apparent even to the un instructed eye. In the days of Hincmar (about 882) it yet retained the mosaics and other ornaments bestowed by her piety. But about 1010, one

of the columns having given way, it was partly rebuilt by Archbishop Poppo. The Roman work is less clearly apparent in the present nave, but Roman bricks abound in the western apse and its side walls; and if it were possible, without injury, to excavate the foundations of the cathedral, the Roman substructure would reappear, showing that, like the Ulpian basilica, it possessed a hemicycle, or tribune at either end. This hemicycle, having been retained when the basilica was consecrated to Christianity, gave the peculiarity of form, the double choir, by which the churches, of which the Dom of Treves is the prototype, are distinguished from all other in Christendom. Upon the nature of the vaulting we have already remarked. On the exterior, the architectural arrangement, including the magnificent apsidal gallery, was suggested by the pillars and arches of the circular towers which ornament rather than defend the Porta Nigra, the Roman gateway of Treves. By the slightest overlaying of the pencil, the more perfect of these towers (as seen in the view of Mr. Dawson Turner's interesting "Antiquities of Treves") will acquire, from basement to summit, the general aspect of the Teuton Romanesque apse, as seen in the extreme northern example at Cologne, and the farthest southern, annexed to the church of Pammachius at Rome.

#### The Relation of the Artist to Art.

J. FERGUSSON.

One of the most fundamental rules of art is that sordid minds cannot express elevation, the impure cannot express purity, or the vulgar mind elegance. If we want lofty, pure, and elegant art we must go to minds where those feelings exist, for all arts are the reflex of the individual or the nation practising them, and the improvement must come from within, either from more sedulous cultivation of purity and the higher emotions, or by a more honest and straightforward mode of expression than has hitherto been adopted. On the other hand, we may feel perfectly certain that all that is bad in the individual or the nation will come out in their art, however much they may attempt to disguise it by foreign costumes or plumes borrowed from those who were artists not only in form but in spirit. Art must come from the heart, and can only come from thence.

#### The Windows of Altenberg Abbey.

E. SHARPE.

The most beautiful stained-glass that I ever beheld I saw in the ruined abbey church of a Cistercian monastery in 1832. It was designed, in all probability, just at the time when the severity of the rules of the Order in this respect, as also in others, began to be relaxed. The abbey, of which this church formed a part, was founded in the year 1133 at Altenberg, near Cologne, by Eberhard, Count of Berg, whose descendants rebuilt the abbey church, from the designs and under the superintendence, it is said, of Erwin von Steinbach, the architect of Cologne Cathedral, in the latter part of the thirteenth century. At the dissolution of the monasteries the abbey was converted into a manufactory, and suffered from a fire in 1815, which destroyed the conventual buildings and injured the church; but when I visited it, in 1832, the church, though roofless and in ruins, still retained the whole of its magnificent Geometrical windows, filled with the most elegant stained-glass. The Prussian Government has, I believe, since restored the roof and repaired the church, and, it is to be hoped, has thereby saved the glass. The design of the building, which, from its windows and moulded detail, belongs evidently to the period ascribed to it, bears in every part the impress of its Cistercian origin, simplicity and elegance of design being its chief characteristics. It is lofty and of noble and stately proportions, but entirely devoid of all florid ornamentation, what carved work there is, chiefly in the pier-capitals, having much gracefulness in its composition. It is, however, to the stained-glass of its noble windows that I desire to call the attention of those who are interested in the subject. It is scarcely necessary to say that they contain no "pictures," and no patches of gaudy colour. They consist, in fact, exclusively of designs of foliage, arabesques, and diaperwork of the greatest elegance, and of infinite variety, arranged chiefly in geometrical patterns executed in grisaille and other light colours, and belong in all probability to the latter part of the period in which the church was built—that is to say, to the latter part of the thirteenth and the commencement of the fourteenth century; in other words, to the very best period of Christian art. Of the artistic nature of these designs, and of the admirable manner and material in which they are executed, it is impossible to speak too highly. Of even feminine fairness and gracefulness, they surpass, in my opinion, all the examples of this kind that we have in this country, not excepting the Five Sisters of York; and if, in the matter of stained-glass, it were desired to select works of art that would most fitly typify and represent the purity and simplicity of Anglican worship, I should not hesitate to indicate the windows of Altenberg Abbey Church as the models we should adopt.

## NOTES AND COMMENTS.

IN the International Exhibition of Paris, as in all which preceded it, the British Section is likely to be the first which will be completed. M. GEORGES BERGER has advised the committees of the remaining foreign sections to try and imitate the example set by Great Britain. It appears that the fixing of the machinery from this country can be commenced on New Year's Day, as the building to contain the machines is approaching completion. Between January 1 and February 15 the glass cases for goods must be fixed in their places. The Commission appears to be resolute at present, and we hope there will be no relaxation of the regulations, otherwise the old story of an incomplete Exhibition on the day of opening will be retold. The regulations about admissions are settled. Entrance can be obtained in the daytime on payment of a franc, except in the hours "affectées aux études," when the charge will be two francs. In the evenings two francs will be paid unless on Sundays, when the charge is to be reduced to one franc. The charges for admission to fêtes in the evening will be according to special decisions. Season-tickets will cost one hundred francs, but members of commissions and committees will pay only twenty-six francs. There will be tickets available during a limited time for members of foreign commissions. Every exhibitor is to receive a ticket, but if he should require the aid of stallkeepers or employés, "jetons de service" will be supplied.

THE standard for draughtsmen in the offices of the supervising architect of the Treasury Department and quartermaster-general of the War Department, United States, is very high, and is to be tested by the Civil Service Commission. A two days' examination was held last week in four cities. In the Treasury Office the draughtsman must possess a thorough knowledge of architecture, with the ability to design and construct public buildings, to calculate the strength of materials and structures, and to make detailed drawings, &c. The quartermaster-general's requirements are more modest, as they consist in a knowledge of construction and designing of ordinary dwelling-houses, a knowledge of building material, and ability to prepare working drawings and specifications. Assistant sanitary engineers were also required, with a thorough knowledge of plumbing and capability to make plans for the drainage of large buildings. These conditions denote that a reform is in operation in the public offices of America. We hope the successful candidates will not depend on the whims of politicians for their tenure of office.

STOTHARD'S original drawings have a charm which is not visible in the copies made from them by engravers. Although he made many designs for the illustrations of books, none of his work shows sign of carelessness, and generally there is a grace which was not always found in his larger paintings. The Nottingham Castle Museum is, therefore, fortunate in possessing a large number of STOTHARD'S drawings, which Mr. FELIX JOSEPH presented. He has just added a set of twelve more. These are not the only gifts which came from Mr. JOSEPH'S valuable collection.

THE inquest upon the bodies of the men who were killed by the fall of the new house in Great Titchfield Street, on the 9th inst., was resumed on Wednesday, without adding much to the knowledge of the causes of the accident. The foreman said the soil was gravel, and the foundations were 14 feet 6 inches below the level of the street. There was a bed of concrete 2 feet 2 inches deep. A wall 14 inches thick was carried up from the basement to the street level. The columns were 5½ inches diameter, and rested on York stone 6 inches in thickness. The common complaint in the metropolis reached the coroner's ears, and he asked whether sand and gravel had been removed and rubbish used instead, but the foreman denied the statement. The travelling foreman said he made examinations almost daily, and everything appeared satisfactory on those occasions. The only admissions he made were, that since the accident, he considered the 14-inch wall was too weak, that the brickwork on which the girder rested had given way, and that as the gravel was not even, about a yard and a half had to be removed. Mr. WALTER MILLER, the architect, said he did not see the foundations put in, as he was

away, but the work was done under the superintendence of an assistant. He spent about three or four hours on the works, and had no fear about the stability of the building. A great deal seems to be made about stacking bricks on the ground-floor, weighing 70 or 80 tons. Mr. MILLER said the accident might possibly have happened by the bricks causing the wall to become ruptured, or receive a shock before it was properly set. He admitted that parts of the wall were bonded with half-bricks instead of whole ones, but could not ascribe the accident to that cause. Mr. MILLER maintained that a detached 14-inch wall was fit to carry the columns and superincumbent weight. A chemist testified to the excellence of the mortar. We said at first that the affair is a mystery, and the same word is used by the architect. The inquiry will begin again on Wednesday, but it would be more convenient if there were shorter intervals between the sittings of the coroner.

A NOVELTY of a dramatic kind may appear to be an impossibility in Paris, but one has been introduced by M. HENRI SIGNORET, who is a well-known journalist. His theory is that students of dramatic literature can only be partially informed at the present time. They have no means of judging of the drama of Greece, Rome, India, Spain, or Italy, of Mediaeval passion plays, of the ancient "jeux des pois pilés," of the works of the great contemporaries of SHAKESPEARE in any city of Europe. The students are, however, too limited in number to allow an experiment by a manager in the ordinary way, unless he was ambitious to find himself in a state of bankruptcy. M. SIGNORET, recognising the difficulty, has devised a plan of overcoming it. He has taken the Petit Théâtre of the Salle Vivienne, and there he presents the old plays with stuffed figures instead of the living players. Several writers have come to M. SIGNORET'S aid as translators and readers, and artists have painted the scenes for him and have designed the costumes. Already the "Guardian Vigilante" of CERVANTES, and the "Birds" of ARISTOPHANES, have been played. On Saturday last M. SIGNORET made a more remarkable experiment. This was the production of SHAKESPEARE'S "Tempest," according to a translation of M. MAURICE BOUCHOR. The "machinery" of the play was constructed with care, and the destruction of the King's ship, the strange shapes bringing in and vanishing with the banquet, the spirits in guise of dogs and hounds, and the other tricks of ARIEL were displayed. The theatre is only opened occasionally, and it is exciting much interest. The experiment could be instituted with advantage in other cities.

THE French Minister of Commerce and Industry has nominated M. DE DRAMARD, the president of the Society of Arts of Paris, to be a member of the Organising Committee for the International Congress of Architects, which it is proposed to hold next year in Paris.

MESSRS. MEASURES BROS. & Co. have brought out their annual series of tables of weights and strengths of girders and columns, sections of beams, diagrams of roofs, sashes, wrought-iron doors, and other information relating to ironwork. Experience has shown the possibility of improving Messrs. MEASURES'S pocket guide, and this year's edition is more portable and more convenient for reference than its predecessors. Although of a very small size and little thicker than an ordinary letter, it is on its subject a book of reference. From the wide experience of the firm, the information can be taken as trustworthy.

A POSTERN-GATE in the outer wall of Edinburgh Castle, which was built up several years ago, is supposed to mark the spot where the parting between CLAVERHOUSE and the Duke of GORDON took place. The War Department having sanctioned the removal of the masonry which fills the opening, the work is now in progress, under the direction of Colonel MALCOLM, R.E. Iron bars will be introduced, in order to suggest the original appearance of the postern. The following inscription will be placed over the gate:—"At this postern JOHN GRAHAM of CLAVERHOUSE, Viscount DUNDEE, held a final interview with the Duke of GORDON, Governor of Edinburgh Castle, after quitting the Convention of Estates.—18th March, 1689."

## ILLUSTRATIONS.

DRAINING MILL, LINCOLNSHIRE.

THE original drawing from which the illustration is taken is one of the finest of COTMAN's works. The time is supposed to be evening, and a storm is clearing off. The scene is in the neighbourhood of Croyland Abbey. The original was first exhibited in 1810. We are indebted to Mr. JAMES REEVE, of Norwich, for the use of the drawing.

SKETCHES AT BRITISH MUSEUM.

THESE sketches suggest the wisdom of Professor ROGER SMITH in utilising the treasures of the British Museum for his architectural class. The prize drawings are by Mr. ERNEST RUNTZ, who, although a young man, has already made a name in his profession.

## YORKSHIRE UNION OF ARTISTS.

FOR the advancement of art in Yorkshire a new movement is now afoot, says the *Leeds Mercury*. The Mayor of Bradford will to-day (Monday) declare open to the public the inaugural Exhibition of the Yorkshire Union of Artists. The collection of works for inspection is housed in the gallery of the Bradford Art Museum. The distinction of affording facilities for the opening Exhibition belongs to that borough, because among the chief towns of the county it alone has at present available accommodation. Moreover, the Union owes its inception mainly to gentlemen associated with Bradford. The Exhibition represents the effort of a Society whose objects are the promotion of the general interests of art in Yorkshire by the institution of an annual display of work in the county, the union of existing Societies in the shire, and the holding of a yearly competition and conference in Yorkshire. The Union, on very easy terms, embraces in its membership artists, amateurs, and art students resident or born in the county, and like the shire whose name it bears, it is sufficiently broad to embrace much that is valuable, and should be capable of much that is enduring. It proposes to bring art-workers into closer association, to stimulate culture by providing incentive to emulation, and to afford opportunities for the disposal of work executed. The latter aim is not without value, for, although artists may not live by bread alone, material sustenance is not unnecessary even to artists. The Exhibitions will derive increased interest from the arrangement that work placed in competition must have been completed during the preceding twelve months. A prize fund is to be raised by donations and subscriptions, and the intention at present is to award a gold medal for the best individual work submitted, silver medals to those adjudged the best artists in the advanced sections, and bronze medals to those in the elementary sections. These awards are to be made as the result of a ballot cast by the competitors; though, while those in the advanced section may express their ideas on the works in both departments, those in the elementary section may only vote upon the work exhibited in their own section. The conference, at which the result of the ballot will be made known, is to be held early in January; but the Exhibition itself will remain open until the middle of the following month. In subsequent years it is probable that an art union, for the sale of members' productions, will be arranged.

Apathy and antipathy, usually the lot of new movements, have in this case been in part experienced. Apathy has been found the greater evil. After all, the Society makes a good beginning, so far as moral support is concerned. The patrons and vice-presidents include the Bishop of Ripon, the Lord Mayor of York, the Mayor of Hull, Mr. Josh. Craven, M.P., Mr. Josh. Woodhead, M.P., Mr. George Hull, Mr. Angus Holden, Mr. W. P. Frith, R.A., and Mr. H. Moore, A.R.A.; while its list of members already contains at least three hundred names. The present Exhibition is of more value for what the enterprise promises than for what is already achieved. Embracing very largely the work of amateurs, it is peculiarly strong in water-colour paintings, a fact which is assertive of the national characteristic of our artwork. On the walls, however, also are productions in oils which have had no mean place on the walls of the Royal Academy, and, above all, it is felt by the sponsors of the Society that it might very properly bring together annually in some town of the shire the works of

Yorkshire artists which have with more or less distinction shared in the yearly collections got together under the auspices of the great London societies. For the present venture no restriction was placed upon the number of canvases sent in by members. Out of five hundred received, rather more than half have secured accommodation. On the Hanging and Selecting Committee the towns of Hull, York, Huddersfield, Keighley, Harrogate, Leeds, and Bradford were represented, and pictures from all these, as well as other towns, have places on the walls. Mr. E. Renard, of Saltaire, is the secretary of the Council. The hon. treasurer was Mr. C. J. Durham, of the Bradford Technical College. With these gentlemen the movement practically had its inception. It is to be regretted that only on Friday last the latter succumbed to congestion of the lungs of a week's duration.

## NATIONAL ART CONGRESS IN LIVERPOOL.

THE local committees entrusted with the work of arranging the details of the first Congress of the National Art Association, to be held in Liverpool from Monday to Friday next, met at the town-hall on Monday and Tuesday.

The Congress may be said to be inaugurated on Sunday, when Archdeacon Farrar will preach both morning and evening at the Church for the Blind, Hardman Street, but the actual opening of the proceedings will be on Monday evening, when after a business meeting in the Walker Art Gallery Sir Frederick Leighton, the president of the Royal Academy, will deliver the presidential address in the concert-room at St. George's Hall.

The sectional work commences the following morning, when Professor Aitchison delivers a presidential address in the Architectural Section. The other five sections are:—Painting (president, Mr. L. Alma Tadema), Sculpture (president, Mr. Alfred Gilbert), Applied Art (president, Mr. Walter Crane), Art History and Museums (president, Mr. Sidney Colvin), and National and Municipal Encouragement of Art (president, the Right Hon. A. J. Mundella). The papers to be read on Tuesday morning are:—In the Applied Art Section, by Mr. W. E. Willink, on "The Home Arts Movement;" by Mr. G. H. Garroway, on "The Liverpool Art Workers' Guild;" and by Mr. H. B. Bare, on "A School of the Artistic Handicrafts." In the Painting Section, by Mr. James Towers, on "Encouragement of Local Art;" and by Mr. James Paterson, on "The Cultivation of the Love of Art." In the Sculpture Section, by Mr. G. Simonds, on "The Importance of Sculpture in Civilisation." In the Museums Section, by Mr. E. Rimbault Dibdin, who will give "A Contribution towards the Art History of Liverpool;" and by Mr. Charles Dyall, who will discuss the question "Do Picture Exhibitions promote or impede the Progress of Art?" In the afternoon, after an address by the President of the Painting Section, the papers read will be as follows:—In the Applied Art Section, by Mr. G. H. Morton, jun., on "The Agreement of Colour Theories with Practice;" and by the Rev. H. O. Rawnsley, on "Country Industrial Art Schools: their Aims, Claims, and Needs." In the Museums Section, by Mr. W. M. Conway, on "Reproductions of Ancient Works of Art for Municipal Museums;" and by Lieutenant-General Pitt Rivers, on "The Classification of Objects in Museums." In the Sculpture Section, by Mr. R. Pinker, on "Choice of Materials for Sculptural Decoration;" and in the Architectural Section, by Mr. J. D. Crace, on "The Proper Aims and Limits of the Coloured Decoration of Architecture;" and by Mr. E. J. Tarver, on the subject of the "Proposed Improvements in Theatre Planning."

On Wednesday morning, simultaneously with the presidential address in the Applied Art Section, the other sections will be addressed by the following speakers and on the subjects named:—By Mr. F. Bate, on "The Tendencies of Modern Art;" Mr. R. F. Hallward, on "The Emancipation of the Picture;" Mr. T. Stirling Lee and Mr. Wm. Emerson, on "The Decoration of Public Places and Buildings;" Mr. T. Graham Jackson, on "Obstacles Opposed to the Progress of Architecture by Architects Themselves;" Professor Roger Smith, on "Architecture as part of a Liberal Education;" Mr. J. Pyke Thompson, on "The Turner House at Cardiff;" Mr. Whitworth Wallis, on "A Short Account of the Birmingham Corporation Art Gallery;" and Mr. Edwin Seward, on "The Development of Local Influences for the Advancement of Art." In the afternoon the presidential address will be delivered in the Museum Section, and papers will be read by Mr. W. E. F. Britten on the subject of "Our Claims as Artists," and by Mr. H. H. La Thangue on "Art Education," in the Printing Section; by Mr. J. B. Gibbs on "The Influence of Sculpture on Painting," and by Mr. Walter Armstrong on "The Proper Decorative Use of Sculpture," in the Sculpture Section; by Mr. E. P. Warren on "The Coloured Decorations of Churches," in the Architecture Section; and by Mr. William Morris on the subject of "Art and its Producer," in the Applied Art Section. The day's proceedings will terminate with a reception

by the members of the Royal Institution at the Colquitt Street Gallery; a soirée at the Walker Art Gallery, Rotunda Reading Room, and the Brown Library; a concert at the Grosvenor Room; and an illustrated address at the Rotunda Reading Room, by Mr. Henry Blackburn, on "English and French Modern Art"; the whole to conclude with a Cinderella dance in the Brown Library.

A combined meeting of the Sections of Painting, Architecture, and Applied Art will be addressed on Thursday morning by Mr. G. F. Watts, Mr. J. D. Sedding, and Mr. G. T. Robinson, the latter of whom will read a paper on "Sgraffito and other Processes of Decoration in Plaster." In the Sculpture Section the papers will be by Mr. Onslow Ford on "The Modern Realistic School," by Mr. Samuel Fry on "Architectural Carving," and by Professor W. C. Roberts-Austin, on "The Precious Metals;" and in the Museums Section by Mr. George Wallis on "The Economical Formation of Art Museums for the People," and by Mr. Walter Armstrong on the subject of "Logic in Art." After luncheon, the presidential address will be delivered in the Sculpture Section, and papers will be read in the Applied Art Section by Mr. Lewis F. Day, on "Fashion and Manufactures;" by Sir Philip Magnus, on "The Teaching of Industrial Art;" and by Mr. T. Cobden Saunderson, on "Craft Ideals." In the Painting Section, Mr. John Brett will speak of "The Relation between the Pictorial and the Decorative Arts," and in the Architecture Section, Mr. Basil Champneys, B.A., will dilate upon "Style," and Mr. H. H. Statham on "Nature and Architectural Ornament." At a subsequent combined meeting of the Sections for Museums and National and Municipal Encouragement of Art, Mr. T. C. Horsfall will read a paper on "The Importance of connecting Elementary Schools with Art Galleries," and Mr. P. H. Rathbone an essay on "Lessons from France." A conversazione at the Liverpool Art Club, in Upper Parliament Street, will conclude Thursday's proceedings.

The last day of the Congress will commence with a combined meeting of the Sections of Sculpture, Architecture, and Applied Art, at which papers will be read by Mr. G. Simonds on "Sculpture and its Relation to Architecture," by Mr. J. Belcher on "The Alliance of Sculpture and Architecture," and a third, the title of which is not yet announced, by Mr. J. D. Sedding. In the National and Municipal Encouragement of Art Section Professor Baldwin Brown will speak on "Mural Painting," and Mr. Patrick Geddes on "Economic Arguments for the Encouragement of the Fine Arts." In the afternoon the presidential address in the Art Section will be delivered by the Right Hon. A. J. Mundella, M.P., and of course this is expected to be one of the chief features of the Congress. Mr. W. B. Richmond will subsequently read a paper on "A Strict Method for Study of the Human Figure," in the Painting Section; while in the Architecture Section the papers to be read are by Mr. J. J. Stevenson on "The Planning of Towns," and by Mr. H. Sumners on "The Practical Outcome of the Art Congress." In the evening the members of the Congress will be invited to a conversazione at Streatham Towers, Prince's Road, the residence of Mr. and Mrs. James L. Bowes.

### TOWN-HALLS OF LIVERPOOL.

ON Tuesday a meeting of the Liverpool Architectural Society was held in the Free Library, William Brown Street. Prizes were presented to Messrs. E. Thompson and T. E. Eccles. Sir James Picton read a paper entitled "Notes on the Successive Town-halls of Liverpool." He commenced by a protest against the way in which, in the design of public and important buildings, provincial architects who possessed both local knowledge and interest were passed over in favour of their metropolitan brethren. Owing, he continued, to peculiar circumstances in the rise and progress of the city, Liverpool had very little of architectural antiquity to boast of. The Mediæval castle, and its rival, the feudal stronghold of the Earls of Derby, had long been swept away. So had the quaint and picturesque dwellings which formerly lined the narrow streets. The oldest buildings which remained were St. Peter's Church, the Blue Coat Hospital, and the town-hall. Having touched upon the antiquity and development of municipal institutions generally, Sir James Picton referred to the creation of the borough of Liverpool 700 years ago by King John. In the charter granted by Henry III. in 1229 it was decreed that "the burgesses of the said borough shall have a mercatorial guild, with a hanse and other liberties." The hanse was either mercantile or town dues or a place of assembly for the guild, known originally as the Hanse House. The first building of the kind in Liverpool stood in High Street, opposite the east entrance of the present town-hall. The first reference to it was dated 1513, and was made in a document in which the building was styled the house of the Blessed Virgin. Subsequently it was mentioned as the custom-house, hall of Council, and court-house, and doubtless did duty in all these

capacities. At first it was thatched, but in 1567 it was covered with slates, and the slater had the freedom of the town conferred upon him for life on condition that he kept the roof in repair. The Mayor, in consideration of using it on festive occasions, was required to keep the glass in repair at his own expense. The building was let for "brydals" or weddings, and for dances, at five shillings a time, "to be paid beforehand." From a minute dated 1579 it would appear to have been also used as the town prison, as well as a banqueting-house. The second town-hall, underneath which was the "publick exchange for the merchants," stood in the recess at the corner of Castle Street and Dale Street. It was built in 1673, and was a quaint and neat building of brick with stone dressings, and supported on pillars. In seventy years it became necessary, owing to the growth of the town and the trade of the port, to erect a new town-hall, and in 1749 this structure was commenced on the high cross at the intersection of the principal thoroughfares, north and south and east and west—an unfortunate selection of site, which had involved the Corporation in large sums in opening up equivalent lines of communication. This building was substantially the present structure, and still sufficed when the population of Liverpool had increased 32-fold, and the commerce of the port to 250 times its volume at that time. It was a handsome building, and after various improvements, such as the completion of the north and west sides (which were originally attached to other buildings), and the addition of the north wing, it still, after the lapse of nearly 140 years, fully maintained its claims to recognition as one of our finest architectural examples. It could not compete with the St. George's Hall as regarded grandiose classicality, but for harmonious proportions, simplicity of plan, unobtrusive beauty of detail, and general effect, it had never yet been surpassed. The design was simple, bold, and majestic. There was no intricate complication of the parts, yet there was sufficient variety to avoid monotony. As a whole, it was a building of which Liverpool might be proud, and was a graceful embodiment now, as it was the forecast at the time of its erection, of the mighty commerce which extended its ramifications wherever British enterprise could reach or the British flag float. Sir James Picton was accorded a vote of thanks after his paper.

### ORIGINALITY IN DESIGN.\*

By WILLIAM BRYCE MUNDIE.

IT is said that no art can be called progressive that is not an improvement on what has been done before. To the student of architectural history it must be apparent, that as far as architecture is concerned, it is not an improvement on that of our forefathers; and we are also taught that if we had studied diligently what our forefathers had done and had profited by their experiences, by their failures and successes, we should have long ago outstripped and gone beyond them, and, backed by the historical reference, I deduce that our great fault has been a lack of directness of aim and idea in our design in order to become, apart from anything else, unique, odd and uncommon, or a more fitting modern term, "original." Architectural design is the result of much thought and invention. The thought given to it is an effort of the mind which receives its stimulus from the present and future pleasure to be derived from the success of gaining an object sought after. Invention is the effect of this thought effort; it throws a new light on the things most abstruse and produces them in order to fit the intended purpose.

So much for design itself. There are two kinds only: good and bad. Good design is an effort reached after a most deep and thorough investigation of material objects which please or disgust the mind of man, and then, by making a studious collection of whatever may so please that mind, shaping them in the proportionate forms of a building.

This is the manner in which the several styles of architecture which we admire, look up to and endeavour to surpass, were originated and brought to the surface, to sink before our eyes while we struggle to be original.

The necessity for originality in design arises from the fact that it is in the nature of mankind never to be satisfied; the more he sees the more he wants, and the more he has the more he tries to get. If it were not so, then, a building possessing every requisite and convenience in plan and arrangement, of unquestioned stability, no matter how hideous or disgusting to the eye it may appear on the outside, would be all that would of necessity be required in order to constitute a completed structure. But the design of a building is something more than convenience and stability; it indicates to the outside world and to the spectator that others have been thought of or cared for besides the owner, and that the structure was erected not for one alone, but it becomes a part of nature and belongs

\* A paper read before the Chicago Architectural Sketch Club, and published in the *Inland Architect*.

to the world. Therefore it is fortunate for us that a man is not satisfied with the necessities and conveniences of life; he looks forward to acquiring more, going beyond, seeking luxuries and admiring the beautiful; thus giving rise to a third essential in architecture, namely, "design," and any building erected and carried out without thought and study having been bestowed on these three essential points—convenience, stability, and design—is not covered by the term "architecture" at all; it is building; for a structure strictly utilitarian in principle can never be beautiful. A convincing proof of this fact is obtained by looking out of the rear windows of your own house and studying the rear elevations of the houses of those who live in the same block. Everything there, from the ash-box in the alley to the top of the wall, is positively offensive to the eye. Thus it must be conceded that design is necessary to fulfil the laws and requirements of good taste.

It is easy, therefore, to perceive that this same prevailing instinct in man, desiring something more than solidity and fitness, would also desire in a greater degree something other than sameness and repetition; hence originality in design or architecture proper, as I consider the third essential, "design," the highest attainment to which an architect can aspire. A man can construct or study out a plan and be totally unable to design, but a man who can design in a proper architectural interpretation of the word can command all three of these essential points; otherwise from that he approaches the sphere of a decorator, and there is a vast difference between an architect and a decorator. Something more than decoration occupied the minds of the architects of the Old World, who reasoned and thought, constructed and designed, before they decorated.

Originality in decoration has a tendency to aim at extreme novelty. Now, there is no harm in novelty. Taken by itself it may be beautiful, but without a motive it can never be anything but a fault in architecture proper, and when it is sought after solely for the sake of novelty, it is then destructive to both art and good design.

The constant search after novelty by designers to-day is one of the sources of bad taste in our modern architecture, and it is often adopted to save time and study, and thrust upon the public something they barely understand, thus impairing the good taste which the public should be educated up to. Good taste in architecture is a thing of much thought and study; it owes all its value to thought, and it is beyond any man who will not stop to think. He becomes thought-grudging and vulgar; to him pure taste must be utterly unintelligible and almost inaccessible. Even his work will show it on the face, expressing a fickleness, affectation, and thought-flying hurry.

The hunger after novelty in our architecture is getting to be insatiable, and owners as well as architects appear anxious to obtain it, no matter what sacrifice of truth and cost it incurs. Heaven and earth are racked for something novel, and happy is the man who shall hit off something, no matter how bad, if it will only strike the common taste, "catch on," so to speak, and has what we might term the "run of the season." This is certainly originality, but it is rather of an illegitimate sort, and that which the finished designer abhors, yet has to admit in his dealings with a people who are original if they are nothing else, and who seem to possess a belief which is getting to be too prevalent, that knowledge, skill, and taste are inborn in a man, and come by nature, and what may be beauty and excellence in a design is often spoiled and overruled by the owner, who makes no scruple of setting up his own taste against that of the architect, and altering and changing the design at his pleasure.

A certain amount of novelty, or, rather, the searching after it, might be termed original in design, especially in the formation of any new style; but a new style is not developed in a day; therefore, novelty is admissible only in a comparatively small degree.

The distinction between novelty and what we call legitimate originality is rather difficult to determine, and what we term legitimate originality is hard to define: but the architect to-day who catches at the spirit of true architecture, and not that of any one style, and who can successfully combine these two attributes, making a pleasing fusion with the present style in vogue, is regarded as being original, and is likely to be the recipient of favourite commissions; hence the inclination to be original, or counted as such, on the part of the architect; for Americans like originality; they possess abundance of it themselves, and as far as that which pertains to designing the construction of our buildings is concerned, they beat all creation; but too much of their design proper is irrational and lacking of a definite aim. If there is such a thing as one nation's possessing more originality than another, America should, on account of her mixed population from all parts of the civilised world, each one bringing with him from his native country new ideas, &c.; but all these ideas, good in themselves, no doubt cannot be put through the mill at once, and we look to time to ultimately accept or reject, and engraft those acceptable into one another, each in its proper place, and this cannot

be accomplished without considerable ingenuity and originality on the part of our designers themselves.

It has frequently been asserted that we, in America, who have no past history, should cast off all conventionalism, using no precedent to govern the design of our buildings, thereby forming a style of our own, and of our own materials. Now, while it is not my desire here to approach the hackneyed subject of an American style, I speak of it merely looking toward the great point which would underlie such a thing, namely, originality. First of all, it is against nature, science, and art to ignore the past. You cannot do in a day or a generation what has been accomplished in a thousand years; besides, the enlightened people of this country, original as they are, would rebel against being used as subjects for experiment on such a large and stupendous scale; moreover, we do not need any such sweeping change. We are too original now; our design to-day is too eccentric and erratic, the result, I think, as I saw it mentioned somewhere recently, of the fact that we are, in a measure, living in a practical age; scores of young men who once intended to enter the learned professions, as they are called, are to-day leaving our colleges and entering into the practical pursuits, as the vast needs of our time and country demand better attention and educated study bestowed upon our architecture, engineering, and science, and the result of the fusion of this vigorous young blood is to be original at any sacrifice. Still the peculiarities of a few years ago show a more sober and quieting expression; there is a perceptible rational and true, showing that we are slowly recognising the toning-down effect prevalent in the work to-day that is more deficiency of truth, thought, and reason in aim and idea.

It is in our city buildings that we fail most; our suburban and country Domestic architecture is original, beautiful, and true, and above comparison with other nations, but there is room for improvement in our city residences, though of late there has been a great improvement in this class; still they lack dignity, repose, and expression, more the fault of the owners than the architects, for the owners of our city mansions lack dignity in their manner of living, on account of the immense success of the suburban residence, which retains the charm of American home sentiment which pervades it, and this will be a difficult matter to overcome, if it ever can be accomplished.

Our business buildings are lacking most of those qualities which are so essential to good design, breadth, harmony, repose, and continuity of line and surface, and here again the practical age asserts itself; the first storey of a many-storeyed building must approach as near as possible that of a conservatory; the store tenant must have it so, in order that he can make his inartistic display; bay windows, frequently many storeys high, constructed on sham principles, are made to project out of the top of the conservatory without any visible means of support other than a *repoussé*, fancy copper bottom. Nevertheless, the tenant must have it, and there appears to be no help for it but to wait for an uneducated public to learn to appreciate and recognise the beautiful and true consistencies of architectural art. The chances are that we to-day may not see it, but we hope for the future.

How can we become legitimately termed "original"? It is said to be impossible for a designer to produce anything true unless he appeals to nature; it is also an axiom that he can produce nothing new unless he possesses a knowledge of what has been done before. The most original architects are or have been the most extensive imitators, and I think, without exception, that all the men of genius that I have known or read of, whether architects or not, have been assiduous and persistent workers and ardent students of the masterpieces of their forefathers. Take, for instance, the value of the example of the late Mr. H. H. Richardson, who will not be charged with any lack of originality, yet his whole life was a personal exemplification of the foregoing facts. The value of Mr. Richardson's example also lay not in the style he chose but in his power to adapt it to the qualities of design at which he aimed—in other words, the use he made of it in his untiring efforts to express certain high qualities in design which others had neglected, and when once he found them he steadfastly adhered to his convictions. To-day we haste to imitate his most common features, details, &c., which appear most in different places, altogether ignoring the breadth, subordination, simplicity, and repose peculiar to his work, and the aim and idea which is apparent to one who strives to fathom the measure of his liking for his style.

In connection with originality Sir Joshua Reynolds says:—"He who resolves to search no mind but his own will soon be obliged to imitate himself." He also states, regarding invention:—"Invention, strictly speaking, is little more than a new combination of those images which have previously gathered and deposited in the memory. Nothing can come of nothing. He who has laid up no materials can produce no combinations." Therefore, the more extensive our knowledge is of the works of others who have excelled in their art, the more extensive will

be our own ideas and inventions, and the more original will be our conceptions.

Sir George Macfarren, in his last address to the Royal Academy of Music, gave the following advice to students and young composers. I do not quote his exact words, as it pertained to the composition of music, but the main ideas are applicable alike to the young composer and the young designer; therefore I take the liberty to insert the word design for that of compose, and reconstruct a few sentences; but let every young aspirant in design think thoughtfully over them.

"Those who design must make mental studies; it is not to occasionally design a piece of furniture, or an elevation, but to have a constant habit of constructing things, of planning arrangements and exercising the faculty of invention and design, for it is never in the career of a designer to say 'I have finished.' It is the constant seeking advancement which is the real means of developing the faculties wherewith nature has endowed us all. In order, therefore, to master the art fully, and to do justice to the productions of present times, they must have a knowledge of the works of preceding periods. Let them work at the productions of the masters of former times, and then see the productions of their own. They will then have the conviction that originality can only find its proper expression when they have commanded, by constant exercise, such power over their faculties as would enable them to produce that which is in themselves."

Thus it will be seen that to study the ancient styles is indispensable. By study I do not intend that we should make exact copies of the works of the ancients, but study the why and wherefore; the reason and motive for adopting this feature and that feature, which, should you adopt it at all, you would so modernise it that everything except the aim and intention would wear a changed appearance. This manner of study will give us sufficient knowledge of the forms of the past, and will teach us to use their principles and not their forms, for the customs of the people and the age in which we live dictate to us and resolve into shape the form of a building we should erect.

I think, also, that a knowledge of the styles of the past is desirable, in order that we may perpetuate and modify those architectural forms given us, adapting that which to us may appear best to our present requirements, considering how to make the most possible and most rational use of that which is handed down to us, and blending it with that which our own age, knowledge, and materials supply us, for changed materials in the past few years have altered our whole system of construction and utility, and in architecture, as in other arts, two things must always be borne in mind—the intention, and the materials used to express and carry out that intention.

It would certainly be the height of folly to ignore and cast aside all that which has been handed down to us by those who, in their day, thought almost entirely for themselves. They did not receive weekly or monthly several technical journals, &c., each exhibiting plans and designs of every constructible under the sun; and here lies an open question—Whether it would not be better to make us depend more on ourselves, thereby forcing us to bestow more thought and study on our designs, if we did not receive so many of these ready-made ideas? It would certainly be cultivating true originality on our part.

The man who gets an idea from an ancient or even a modern architect and designer and so engrafts it into his own work that it becomes harmonious throughout can hardly be charged with plagiarism, nor should this use or adaptation of the actual designs of others be accounted an architectural sin, for it may frequently happen that two inventive minds may run along in almost the same channel affording almost similar results, yet each totally ignorant of the doings of the other. Before leaving the question of imitating the ideas of others, let me add that the great success and value of this borrowing does not lie in the exact copy or correctness of imitation, but it depends greatly if not entirely on the designer and on the headwork he displays with the breadth of generalisation that accompanies it; for that which simply imitates without generalising, even though the model possess many excellences, does not approach art at all; and it might be well to pause here and note this fact, that nothing but good examples should be used for the purpose of study, otherwise originality is less to be hoped for in each succeeding age, for a designer will reproduce something of the works through which his studies have been made, imperceptible though it may be at the time to himself. It may also be said regarding the study of the examples of others, if a thing is good, is it not too good to be given up? If so, is it not too good to be caricatured and abused, or, in other words, if it is worth copying at all is it not worth copying completely?

Yes; but this can never be done without copying also its construction, and how often will this somewhat out of date idea work in and adapt itself without any alteration whatever, and fill the place completely? Never, as long as our modern habits, materials, and means keep changing; and the same applies to design or style as well as construction. The rest of the build-

ing is laid out on a modern basis; then the feature, good in itself in every way, and in its own position from whence it came, will become hideous and out of character with the rest of the work.

The old styles are and perhaps ever will be imitated, as by far the greater number of our works to-day are based upon imitations; but the designer must go with the spirit of his own time or else be able or strong enough to lead it, for the period of style in which we live not only makes the designer as much as he makes the period, and when I say the spirit of his own time I do not mean the prevailing fashion, fads, and eccentricities that are prevalent at that time, though to some to-day this appears to be all important, and any new publication by architects of reputation, or any work of decoration in process of execution from their designs, is eagerly sought as a source of present profit, and considered more valuable than in the end, being led to a fuller sense of the beautiful and true at the expense of attaining facility, readiness, and being well up with the prevailing fashion in which he lives. Architecture does not consist in a series of fads, fashions, and erratic novelties, each having its own successful run to die a death and pass into oblivion; it is something higher and nobler, expressing in materials ideas which have truth for their beginning and ending.

We should aim at catching the true spirit of architecture, and not that of any one style, much less a fashion of the day, which depletes our stock-in-trade at the end of its questionable run, finding that we must begin over again, starting on a new tack, cruising round with a weather eye bent on the doings of others, hoping to pick up some clue or purpose that would help solve the problem; still, at the same time, this quality, this searching the doings of others, is of considerable importance, and not unattended with benefit to the searcher, as I think every reflective man should post himself on the doings of others who are co-workers in the field for and against him, endeavouring to get at all sides of the case, holding himself as an umpire, forming his own opinion of its merits and passing judgment upon it. We become in design akin to our politics and religion, prejudiced, and all in favour of one style or period, and stand still by it until others have left it and gone off into something else which is more taking; then we are at sea with ourselves unless we possess that knowledge of what has been done of the kind before. Should we possess this knowledge, then is the time to adopt the new, adapting that which is rational and fit and applicable, avoiding peculiarities and eccentricities of style at first, though this will be found difficult to do, as it seems born in the nature of imitators to seize on the most salient points of good or bad design and exaggerate them. Peculiarities in design and style are generally defects. It is by peculiar features that we distinguish one style from another, and it is by these peculiarities that any one will recognise the style at first sight, and which any mechanic may copy, that mislead and cause designers to veer round from one thing to another without showing any search for the real excellences of the style; these lie deep below the general first glance, and require considerable thought and study to enable one to eliminate them, not to speak of adapting it to fill a certain requirement in what we term a more modern style.

This imitation of peculiar features in design, which are oftentimes inessential and mistaken for beauty, will most often appear in the work of a designer who has one favourite master, and even though he choose the best work and is capable of discerning good from bad, will never obtain in this way what we would call originality in the mastery of his art. Slightly new features, however, can be introduced into our designs with considerable success, providing the new can be fused with the old in a legitimate manner, and the monotony of our work becomes somewhat relieved in this way; but if this new element is too new and foreign, it becomes difficult to fuse with the old, our eye seeming equally to hate too wide a deviation at all. Or, in other words, if any one gives us a new idea, which is not too far ahead of us, such an idea is often of great service to us, and may help to give new life to our work. In fact, we soon fall back unless we more or less frequently come in contact with new ideas and are capable of understanding and making use of them; but, on the other hand, if these new ideas are too new and too little led up to they put us out with every degree of completeness.

After all, there is no better foundation for good design than the act of searching for the principles which govern it, and when found by steadfastly adhering to them; there is no other royal road to it. Beauty of form should first be sought after and acquired, and then the leading lines decorated. No amount of effective ornament, original as it may be in itself, will ever make an original and good design, though few architects seem to acknowledge this either in practice or theory. The rule that the greater should regulate the less should follow in a building; the building blocked out roughly, should regulate the design and ornament, and also all which it contains; furniture and decorations should all conform to its characteristics, thus giving a proper uniformity of style and design through-

out and a subordination of all inferior objects to those of greater importance, giving a broad and widespread sentiment, which I am afraid in our times is wanting, for how many people, and wealthy people, too, erect their houses with rooms totally incongruous in character the one to the other, the same applying to the furniture, &c., till the house is like a museum, showing a vulgarised taste and a false belief of beauty and uniformity, for unity of design, style, and decoration of all things that are parts of a whole are indispensable to true taste.

Let us take, for instance, the case of the general client of to-day. I may say there are some exceptions to him for which we are truly thankful. He enters an architect's office and starts the conversation by stating his wants, desires, &c., in regard to the future house. His greatest want invariably is to get the house for half what it will surely cost him. His next want is to design the house from within, and in this he has an able second in the personage of his wife, or daughter, as the case may be, sometimes both, and oftentimes several more. He proceeds by jumps of one room at a time, without any general or definite idea of the whole. He wants the hall like Mr. Someoneelse's hall, the dining-room like that of some other house, and so on, utterly regardless of anything else but to have them just so, and nine times out of ten when he gets it that way it is not what he wants at all; it is but a taking fancy of the moment, and he allows it to mislead him without thinking it over seriously, for when completed, Mr. Someoneelse's hall and Mr. Otherhouse's dining-room are entirely of a different plan and feeling from each other, and so on throughout the house; they were all designed by different minds on different principles, probably the hall from a sea-shore cottage, and the dining-room from a city mansion; but no matter, they pay their money, and they must have it. Thus the architect receives his idea of the future house, from basement to roof, and he makes his plan accordingly. Then he is confronted with one of the meanest tasks which can be imposed upon a designer who takes any pride in his work at all, namely, to design an interior to fit the plan as laid out, a scheme as ridiculous in principle as making the window openings to fit some old sash that may be on hand. The whole house has been designed from within, without reference to the multitude without; the man without is confronted with a flat, featureless pile showing lack of thought and study, the salient corners and the recesses of the given plan forcing upon the public an eyesore to which they must become accustomed, and thus the general taste and culture of the masses is undermined, and all for the sake of one "must have it" individual, who, let him live in his house ten or fifteen years, will probably tear out and alter anew the inside, but the outside swears on at the public for a quarter of a century.

On the other hand, you may say, who will occupy this house when finished, the owner or the spectator? Is it not the owner's privilege to do as he pleases, to so plan his house as he wishes? Certainly it is he who owns the inside and nominally the outside, let us grant him that; but the public are entitled to some consideration, for every man born in this world owns his just share of this earth as nature designed it, and no one has any right to artificially despoil her. It is the duty of the owner to consult the observer, to erect what will not prove an eyesore and a nuisance to the general public. Thus it is that the best ornamental detail, feature, and design is not only required but really demanded by the laws of nature and taste, and it is by the abominable treatment of these laws that we have so much of, what I term, enforced originality in our architecture to-day. This forcing upon the designer set and rigid requirements is not only bad in itself, but leads to others; he sees the hopeless task before him, and sets to work on the next best thing by sticking an ornament wherever there is a place for it, usually where it will be most conspicuous, not where it will most improve the building; but this deception is thin. No one is so easily deceived. You cannot hide the want of thought and study by any amount of ornamental frippery; in fact, it is rendered all the more offensive by adding ostentation to it. This the observer does not want. He cares not for ornament, which shows that the owner possesses so much money, but he does care for the owner and for the owner's consideration bestowed on him. Nothing short of this will satisfy the spectator. Show him by thought and study that his wants have been considered.

Of course, I do not wish to imply in these foregoing remarks that ornament is not essential to beauty; quite the contrary. It is really a natural want. The rudest savage shows some affiliation for it, but as some men to-day buy and wear their jewellery a size larger than any one else, it is so with a great deal of imitative ornament—always a size larger than our neighbours, more imprudent than the true thing, exciting our contempt by the meanness and vulgarity it displays on the building it is intended to adorn. See how nature ornaments and decorates herself; there we may learn something of restraint and be warned against over-ornamentation; just see how she restricts her true ornaments (the flowers) to the most telling and culminating points of plants, sprinkling them

sparingly, and contrasting them with a vast expanse of foliage, while we, by the many artificial aids, strive to force her to the opposite by demanding more ornament than background. Seeing this, should we not liken unto nature our great and only teacher, follow her dictates on this point and concentrate ornament, leaving wall spaces intact?

Before leaving this point of ornamentation I wish to make more clear a foregoing statement, "that ornament is essential to beauty," by saying that at the same time it is not always necessary, for strip a house of its ornament if it is still in harmony, if it still retains its pleasing proportions, it is not necessary that its ornament be restored; but, if restored, it will not be added in vain, provided it be properly placed and consistent with the style and character of the work; if it is not pleasing when stripped of its finery, then no amount of ornament can atone for lack of design and proportion.

In conclusion, if any views of practical value are herein advanced, if they be admitted as worthy of discussion at all, they will, I hope, be of value as regards the betterment of the profession individually and collectively. First, we grant the public the right to demand beauty and truth in our buildings, and does it not then become our duty as architects and designers to endeavour to educate the public to recognise this beauty? educate them to the idea that architecture is the highest art? We also see the folly of designing novelties on too large a scale and of not making them at all. We see that new ideas cannot be fused with old, save gradually, and by patiently leading up to them in such a way as to admit of a sensible continuation or identity between the old and the new, even nature wishing to take her own time. I have also pointed out that our great architects, musicians, poets, &c., owe their distinctions more to assimilation and fusion of all the good that has been done up to, and especially near about their own time, than to any very great and startling steps they themselves may have taken in advance. Also, that we should borrow from every style, from every era, and from every form, in order that we may, in time, become original in ourselves. Therefore, let us step forward and take advantage of what has been done before, find out if we possess any of this assimilating power, this power to adapt and complete the fitness of things, not only for our own benefit or advantage, but for the future of a nation whom I hope in the not far distant years will hold the proud distinction, architecturally, in comparison with other nations, that she does politically, commercially and otherwise—the grandest on earth.

#### ORGANISATION OF WORKS DEPARTMENT OF THE LONDON SCHOOL BOARD.

THE following are the recommendations which the Investigation Committee offer upon the organisation of the Works Department of the London School Board:—

That an assistant architect be appointed to superintend the construction of new schools and enlargements.

That in future the architect shall, as an experiment, make use as far as possible of the draughtsmen in his office for visiting the schools and enlargements in course of erection, and that the question of making any addition to the staff for this purpose be settled hereafter.

That upon the approval of the plans and specification, the Works Committee shall nominate a quantity surveyor to take out the quantities.

That six quantity surveyors of known reputation be employed to take out the quantities for the schools of the Board, the remuneration being an agreed percentage, to be calculated on the total amount of the contract (including provisions).

That the outside surveyors appointed by the Board shall receive from the Board's land surveyor a plan of the site, with levels marked thereon, sufficient to calculate the surface when the site is given into the contractor's hands and the standard printed specification, with notes of any variations proposed by the architect. They are to prepare detailed bills of quantities in the manner recommended in the reports of the Board's professional adviser, and to calculate all necessary provisional sums (those for entire buildings excepted). They are to correct the specifications, inserting all additional information necessary fully to make the quantities and specification agree together, and to excise all unnecessary clauses; to give to the builder a copy of the dimensions at his request, and at the cost to him of the actual expense of copying; to deposit the original dimensions, fully indexed, and the abstracts with the architect, and to examine the priced bills when they are deposited, to see that they are fully priced out to the amount of the contract. For these services they are to receive an agreed percentage on the amount of the works above mentioned, and the cost of lithography and any necessary expenses, to be paid direct by the Board when the first certificate is granted to the builder.

That payment to the quantity surveyors be made direct by the Board.

That, previous to the building of any school, the Board shall advertise their willingness to receive tenders for that school from builders who are desirous of tendering.

That the list of applicants shall then be submitted to the Works Committee, and, after consideration by them, tenders shall be invited from those of the applicants who fully satisfy the conditions laid down. (The following is the suggested form of advertisement:—"Persons desirous of contracting for erecting, under conditions laid down by the School Board for London, a new school at \_\_\_\_\_ are invited to submit their names, giving references as to character and work executed, by letter addressed to the clerk of the Board, on or before \_\_\_\_\_")

The Board do not bind themselves to reply to, or to accept, any such application."

That it be an instruction to the Works Committee before inviting a tender from any builder for the erection of any new school or substantial enlargement, to satisfy themselves that the character of the work previously executed by such builder, either under the Board or elsewhere, is of a thoroughly substantial and satisfactory nature.

That a copy of the specifications of all works included in provisions be sent by the architect's department to the clerk of the works, and that he be made responsible for seeing that they are properly executed.

That in all cases where the opinion of an expert is required, as in heating and drainage, such an expert shall be employed by the Board to examine the work, and certify that it is properly executed.

That the measuring-up of variations on schools and enlargements be in all cases done by an officer of the Board.

That the measuring surveyor, who will eventually make up the accounts of buildings, shall measure the foundations at the time that that part of the work is completed; and until the work is finally measured and settled between the Board and the contractor, no work shall be covered up.

That no deviation from the original plans or specification shall be allowed, unless either the sanction of the Works Committee has been previously obtained, or indemnity from the Works Committee obtained at their next meeting.

That the valuing of work executed with a view to granting certificates be made by the measuring surveyor's department in the architect's department.

That the general repairs to schools, except the heating apparatus, gas-fittings and ironwork generally, and the erection of cookery centres, deaf and dumb centres, schoolkeeper's houses or such like work, shall be under the supervision of a superior officer in the architect's department, who shall be generally responsible to the Works Committee.

That clerks of the works for repairs be placed in charge of a number of schools, not exceeding thirty, whose duty it will be to report upon any work requiring to be done from time to time at the schools under their charge in order to keep the building and furniture in proper condition, and superintend the performance of the work, keeping a strict account of the labour and materials consumed, where necessary, for verification of accounts at end of job. That these clerks of the works be assisted by the schoolkeepers, whose duty it will be to point out anything which may not be properly carried out during their absence.

That no clerk of the works shall be nominated to the charge of any works, except with the approval of the Works Committee.

That tenders, based upon schedules of prices, both for general repairs and painting, be obtained, and firms appointed for divisions or groups of schools willing to carry out the work. That no sub-letting be allowed.

That all furniture, such as cupboards, tables, chairs, mats, fire-irons, coal-scuttles, &c., with the exception of desks, be delivered at a store in such quantities and at such times as may be necessary, and there be carefully examined by the Board's officers to see if they comply with the conditions of contract before the account is passed. That desks be delivered at the schools and examined by the clerk of the works in charge of the school. That annual requisitions, countersigned by the managers, be prepared for the purpose, to be made out by the schoolkeepers for all store articles, the requisition to state whether they are required additionally or in lieu of worn-out articles, or if for repair, and to be dealt with in the same manner as requisitions for other stock articles.

That the whole of the clerical staff be placed under the charge of the principal clerk, who in addition to the duties at present devolving upon him, shall have charge of the schoolkeepers, the advertising for all tenders and passing of all accounts on to finance department after they have been certified to by the architect or clerk of the works.

That, in every case where defective foundations have been found to exist, or where work has not been done which has been paid for by the Board, proceedings be taken by the Board against the contractors wherever they are advised that they have grounds for action.

That Mr. Rickman and Mr. Ewan Christian be employed

by the Board for one year to advise in the carrying out of the above recommendations at the same rate of remuneration as hitherto, viz., 10s. 10s. per day of eight hours, counting the actual number of hours they are occupied on the work of the Board.

### ROBERT BOYLE & SON, LIMITED.

THE third annual general meeting of this company was held at the Cannon Street Hotel on the 21st inst., Mr. Gilbert Wood presiding.

The secretary (Mr. J. A. Dargue) having read the notice convening the meeting,

The Chairman said:—It is quite unnecessary to read the report which has been placed in your hands, and I daresay read by all of you, and likewise the balance-sheet accompanying it, and therefore it simply becomes my duty, and a very pleasant duty it is, to tell you that we are again prepared to pay you a dividend of 12 per cent. In many companies the chairman on these occasions has to gild the bitter pill that the shareholders have to swallow, but in this case the pill is of solid gold in the shape of 12% for every 100% invested, and consequently the work of the chairman is very easy. I may say that, from the personal knowledge I have obtained of the position of the company, I am persuaded that next year and the year after next—I think we can see forward as far as that—are not likely to be one iota less prosperous than the years gone before. From the orders we have in hand, and others which we know are coming in, we are in a position to say that the year we are now entering upon will, in all likelihood, be even more prosperous than that just closed. In making this statement I wish to take no personal credit for the satisfactory position the company now holds. For that we have to thank the splendid business abilities of our managing director, seconded by able workmanship and willing assistants in every branch of the company's business. Under these circumstances we can look forward with hope to the future, as we can certainly look upon the past with satisfaction, and it is with great pleasure that I now beg to move the adoption of the report and accounts.

Mr. H. P. Stebbing (a shareholder):—I have much pleasure in seconding the resolution. The accounts which have been presented to us are very satisfactory; not only as good as last year, but as a matter of fact much better, and I think this state of things is likely to give considerable satisfaction to the general body of shareholders.

There being no questions, the report and accounts were then unanimously adopted.

The directors and auditors having been re-elected, Mr. Stebbing proposed a vote of thanks to the chairman and directors for their excellent management of the business during the year, and suggested for their consideration the addition to the board of another director, residing in London, to assist them in their labours. The small attendance of shareholders to-day was, of course, the outcome of the prosperous position of the company, but he was one of those shareholders who made a practice of attending the meetings of companies in which he was interested, as he thought that directors liked to meet the proprietors from year to year, and when the affairs of a company had been so well administered as those of Robert Boyle & Son he thought the least shareholders could do was to come forward and express their thanks to the board.

Mr. Eckstein seconded the resolution, pointing out as a satisfactory feature of the management of the company the small amount down for bad debts in the accounts submitted.

The resolution was unanimously carried.

Mr. Robert Boyle, in acknowledging the vote on behalf of the Board, said:—I have to thank you for the very encouraging expressions you have made with regard to the work of your board, and I have pleasure in taking this opportunity of acknowledging the valuable and disinterested services rendered to the company by our esteemed chairman, Mr. Gilbert Wood, to whose able assistance, along with that of the officials of the company engaged in the Glasgow and London offices and works, we are so much indebted for the present satisfactory state of the business, with regard to which you will see from the directors' report and the balance-sheet that the year ended has been a very successful one in spite of the almost unprecedentedly severe winter and summer, which naturally would be expected to affect the demand for ventilating appliances, as in very cold weather the necessity for a constant change of air in buildings does not so strongly force itself upon the minds of people as is the case when warm weather is experienced. I am glad to say that the demand for the various ventilating appliances manufactured by the company continues to increase both at home and abroad, which may be said to be owing, to a considerable extent, to not only our constant efforts to meet the requirements of our clients, but to the well-proved superiority of the latest improved form of the air-pump ventilator, patented in 1882, which is much more efficient and reliable than any of the

previous forms, and is now sold at about 50 per cent. less than the inferior forms formerly manufactured; at the same time the ventilators are now made of a more ornamental character, and of the best rolled steel plates, galvanised, and painted with enamel paint, whilst the workmanship is of the highest class. Though this, of course, has very considerably reduced our profit on each article, the remarkable increase in the sales, which has resulted from thus reducing our prices to a minimum whilst providing nothing but what is of the best quality, has enabled us to not only again pay a dividend of 12 per cent., but to place one-sixth of the profits to the reserve fund, besides carrying a substantial balance, 1,248*l.* 11*s.* 1*d.* forward to next year. The orders and sales for the past year show, I am pleased to say, a very satisfactory increase on the previous year, though that year was an exceptionally good one, whilst the profits are increased in proportion. We have, of course, as you are aware, rivals in the field, some of whom, however, have dropped out since last we met here, as the majority evidently act on the supposition that they have only to offer a ventilator at a very low price, "got up" to resemble, in external appearance, the air-pump ventilator, to insure a ready sale for it, quite irrespective of its lack of merit and inferior material and workmanship. They sooner or later, however, to their cost discover that architects are quite as well able as other folks to tell a genuine article, also when they are getting value for their money and when they are not, and that certain things, though offered at a seemingly low figure, may be dear at any price. I am pleased to say that the foreign agencies continue to develop in a very satisfactory manner and to yield good results, the air-pump ventilator and other appliances being introduced with considerable success to a large number of important public buildings in Germany, France, Belgium—where the system was applied to the Brussels Exhibition buildings—Holland—one contract being just executed at the Hague, embracing seventy-six air-pump ventilators—Spain, America, the Colonies, and other countries. The ventilators have also been adopted in the Dutch navy, and other important contracts for the ventilation of ships have been secured and executed. Agencies have been established during the year in Norway and Sweden, also in Russia and Italy, and a considerable addition to the business from these sources may be expected.

Mr. Stebbing asked a question regarding orders for railway-carriage ventilators for Germany.

Mr. Boyle said experiments were being made by the German Government on their different lines, but those interested were very careful in coming to a decision, as the substitution of the company's ventilators for those at present in use involved a radical change from the existing system. He might add that he had recently visited the principal towns of Italy, and he was satisfied from what he saw that, with proper push, a fair business could be obtained. He understood that the company was going to be invited to furnish a scheme for the ventilation of the Italian Houses of Parliament, and estimates were at present being prepared for the ventilation of a number of important public buildings in Milan and other towns.

The proceedings then terminated.

#### MASONIC TEMPLE, KIMBERLEY.

THE foundation-stone of a Masonic Temple was laid on Oct. 10, in Dutoitspan Road, Kimberley, the capital of the South African diamond fields. The building will consist of two blocks, attached and communicating with each other, the first block consisting of a double storey building, and the back being the temple. The order of architecture is Corinthian, access to the building being gained through a handsome portico supported by six Corinthian columns and capitals. This opens into a spacious entrance hall, 30 feet by 20 feet. This entrance hall leads into the tilers' hall, which forms a lobby to the temple which is contiguous. The entrance hall is flanked on each side by two degree rooms of the same dimensions, approached from the tilers' hall through separate preparation rooms. These degree rooms will be provided with platforms and pedestals. The temple itself is to be a very substantial building with a good floor, with the three steps and platform at the end. The interior measurement is 60 feet by 35 feet, or about the same size as the town-hall. The decorations will be appropriate Masonic panels on the walls. These panels will be formed between projections which form part of the walls. The masonry work will be 2 feet thick, and the height of the temple from floor to ceiling will be 30 feet; the roof will be massively constructed, and be of the description known as a hammer-beam roof, the projections in the walls noted above being carried right up to the ceiling. The ventilation of the temple is on a novel system, and one which seems particularly suited for such a building. In the solid walls air shafts are being built, about 10 feet high, at stated intervals, and these shafts connect with the underside of the floor, inside the walls; the fresh air is let in under the floor by means of ventilators be-

tween the air shafts, so that plenty of fresh air will be constantly supplied, and no fear need be entertained of anything being heard outside. The vitiated air will be drawn off by means of exhaust pipes fitted in the apex of the roof; thus a vacuum will be caused in the interior which will be immediately filled by fresh air drawn by the inlets connecting with the underside of the floor. On each side of the building lavatories and offices are to be built in a substantial manner, and these will be accessible from the outside as well as inside, thus forming, in case of necessity, additional exits. In the entrance hall is to be a handsome ornamental staircase in the centre, which will be lighted by a large landing light about 10 feet square. The upstairs of the building consists of four degree rooms which average about 20 feet by 15 feet. The front wall is to be finished with balustrading and parapet coping, and other enrichments will be brought into play to add to the appearance of the building. All the windows are to be fitted with revolving window shutters inside. The steps and floor of the portico, all the sills, dressings, &c., are to be of Modder River freestone, so it will be seen that everything is to be done to make the building handsome and substantial. The architect is Mr. H. A. Reid, who was the successful competitor when plans were called for. His design was submitted, and the estimates being within the limit the committee had allowed for, the plans were accepted. The successful tenderers were Messrs. Beckett & Morgan, and, remarkable to say, the tender was not above the estimate. The work is to be carried on under the occasional superintendence of the architect, and it promises to be one of the most massive buildings in Kimberley, and an ornament to the place.

The Masonic Temple is to cost about 4,600*l.*, and in it the business of the various Freemason lodges in Kimberley—the Richard Giddy, Cosmopolitan, Athole, Peace and Harmony and Concord Chapter—will be transacted.

#### CHURCH BUILDING AND RESTORATION.

**Ginderford.**—The foundation-stone of the new parish church of St. Stephen's was laid on the 1st inst. by Lady Crawley Beevey. It will consist of nave and aisles, chancel, vestry, and a lofty tower with spire at the north-west angle. Accommodation will be provided for 567 worshippers, and the plans have been prepared by Mr. E. H. Lingen Barker, of London, Hereford, and Swansea.

**Dursley, Gloucestershire.**—On Thursday, November 22, a new reredos, pulpit, tribune for the clergy, and arcading above the existing choir stalls were dedicated. The reredos, the munificent gift of Mr. and Mrs. Searancke, of the Rangers, Dursley, is arranged in two tiers of subjects, being painted on panels. In the centre of the lower tier, and standing on the super-altar, is a handsome new altar cross of brass and copper. This is the work of Mr. T. J. Gawthorp, of Long Acre, and round it on the reredos are painted, on gold grounds, the heads of Abel, Noah, Abraham, and Melchisedec, flanked on the north side by the "Annunciation," and on the south side by the "Presentation in the Temple." These subjects, being those of events in Our Lord's life of suffering, will always be exposed to view; but those in the upper tier, which portray Our Lord in Glory with attendant saints, can be closed with shutters during solemn seasons. The panel in centre represents Our Lord in Majesty, and in the four shutters, two on either side, are represented kneeling figures of St. James the Great (the patron of the church), St. Mark (patron of the chapel of ease), St. John the Evangelist, St. Mary the Virgin, St. Mary Magdalene, St. John the Baptist, Moses, Daniel, St. Augustine of Hippo, and St. Alban, the proto-martyr of England, with their various emblems and attributes. The outer shutters contain four archangels—Gabriel, Michael, Raphael, and Uriel. Angels in adoration also flank the central panel; the figures are painted on panels of mahogany on gold grounds, with raised diapers and ornaments. These accessories, together with the framework and carvings, are very rich and varied, no mouldings or carvings being repeated. The paintings are the work of Mr. N. H. J. Westlake, F.S.A. The pulpit is of oak, and is the offering of members of the old Dursley family of Vizard, as a memorial to their father and mother, and bears the inscription at the level of its floor:—"Ad : DEI : gloriam : et : in : memoriam : Johannis : et : Mariæ : Leigh : Vizard : 1888." It is octagonal on plan, and the traceries, panels, shafts, and mouldings are, like those of the reredos, very rich and varied. The cornice contains shields with various emblems of Our Lord's Passion, surrounded with rich carvings of the oak, vine, &c., the whole being supported on a central column, with eight shafts grouped round it. The backs to existing choir stalls (arranged to fit in with the beautiful new organ, the gift of Mrs. Eyre, of Kingshill, Dursley), and the desks to the subcellia are designed in harmony therewith, with traceries and columns having caps, zones, and bases, the whole crowned with a coved and moulded cornice; those on north side being the gift of

Mr. George Wenden, of Dursley. The three canopied stalls for the clergy are also designed in harmony with the stalls in the chancel, and are the gift of the rector and Mrs. Gresley. The whole of the works have been carried out from the designs and under the personal direction of Mr. E. Swinfen Harris, F.R.I.B.A., architect, of 32 Craven Street, Charing Cross, London, and Stony Stratford; the whole of the oakwork was done by Mr. W. R. Watson, of Stony Stratford, and the carving by Mr. Sewell, of St. Albans.

**Rishton, near Blackburn.**—The church of SS. Peter and Paul, Rishton, will be reopened on Sunday next (December 2), after an interval of nine weeks, during which it has undergone a thorough decoration. The work has been carried out, from drawings prepared by Messrs. Simpson & Duckworth, architects, Blackburn, by Messrs. Heighway & Son, decorators, Manchester, under the direction of the Church Committee. The vicar is the Rev. H. West, B.A. The general colouring is in light and warm tones, in harmony with the prevailing tints of the stonework. The nave and aisles are painted in light terra-cotta, with cream bands and stencilled ornaments, the transepts being more elaborately decorated. The decorations of the chancel are very effective. On the east wall are painted full-sized figures of the patron saints on gold ground panels; the wall under on each side of the reredos is hung with rich tapestry. The cost of the decorations is about 250/. A new organ has been erected by Messrs. Forster & Andrews, Hull, at a cost of over 600/.

### NEW BUILDINGS.

**Hotel Mont Dore, Bournemouth.**—The rapid growth of Bournemouth in popular favour and in actual size has induced the proprietors of the Hotel Mont Dore to carry out some important extensions and improvements, embracing the application of several of the most modern developments of engineering. At the west end a new wing has been added, containing a handsome dining-room capable of seating 100 guests, the upper floors being devoted to private suites of rooms. At the opposite extreme are a winter garden and a commodious covered tennis-court, fitted with a gallery at one end, and at the other a platform and organ, rendering the building available for concerts, &c. The whole of the hotel and recent additions are fitted with electric light, about 300 lamps being employed, ranging from eight to sixteen candles. The power is supplied by a 20 horse-power vertical engine and dynamo combined, of the well-known Raworth type, manufactured by Messrs. Browett & Lindley. The machinery has been supplied by the Anglo-American Brush Corporation, London, and the connections, lamps, and fittings, by Messrs. Edmundson & Co., of Westminster. An entirely new hydraulic lift service has been erected by Messrs. Archibald Smith & Stevens, of London, consisting of two of their patent "Reliance" lifts and requisite power machinery. One lift has an unusually handsome cage, in hard woods, with hand-painted panels and electric light. This conveys passengers to all floors, and is available at all hours. Having regard to the peculiar requirements of a hydropathic, special precautions have been employed to insure the silent running of the lifts, although the ascent may be made in eighteen seconds, and either car can make forty-eight complete trips up and down per hour. The pressure used is 700 lbs. per square inch, supplied through an accumulator by some specially-designed steam-pumps. These are of duplex type, with ram and bucket pump ends, and run with absolute silence. They are fixed at some considerable distance from the accumulator, necessitating some different system of automatic control from the chain arrangement usually employed. This is given by a very simple valve in the steam-pipe, in which the steam pressure is used in opposition to the hydraulic pressure, each being alternately caused to preponderate by hydraulic connection from the accumulator. The movement of the controlling valve is virtually invisible, with the result that immediately a lift at the far end of the building commences the ascent, the pump starts into motion by no visible agency, and continues working till the water consumed is replaced, when it stops in the same manner, only to restart at the next draught of water, the entire system being automatic and silent. Steam is supplied for the electric, hydraulic, and pumping machinery, and for heating and cooking purposes, by a 55 horse-power Babcock & Wilcox boiler, carrying a pressure of 90 lbs. Reducing valves are supplied for the cooking and heating systems. An independent water supply has been obtained by sinking a large well, about 16 feet diameter in the grounds. The quantity obtained is ample, and the quality all that can be desired. The water will be raised to tanks in the tower by a Worthington duplex pump. A separate pumping plant is employed to supply sea water direct from the shore, a quarter of a mile distant, to the baths. For this purpose a Crossley's "Otto" gas-engine is in use. With the improvements above enumerated, the Hotel Mont Dore should take front rank among the hydropathics and winter resorts of the country, and forms another example of the

ubiquity of the modern engineer. The work has been carried out under the superintendence of Mr. S. Chadwick, Parliament Street, Westminster, as architect, and Mr. K. Mackenzie, of 15 Great George Street, as consulting engineer. The builder was Mr. M'Williams, of Bournemouth, and the tennis-court was erected by Mr. Humphries.

### GENERAL.

**The Fourth Annual Exhibition** of the Aberdeen Artists' Society will be opened by the Marquis of Huntly.

**The Glasgow Exhibition** has produced a balance of 50,000/., out of which it is expected that both an Art Gallery for the city and a suitable building for the Mitchell Free Library will be provided.

**The Exhibition of the Water-Colour Society** will be opened on Monday.

**Mr. R. Beavis** has a collection of subjects from Spanish life exhibiting in the galleries of Messrs. Tooth.

**A Grand Exhibition** is suggested to be held in Leeds in the year 1890.

**A Stained-glass Window** is proposed as a memorial of the late rector of Warrington parish church, to be placed in the Asherton chapel.

**A Sum of 600/.** has been subscribed to the fund for the erection of a Burns statue in Ayr.

**A Carved Reredos** in white alabaster, designed by Mr. R. Knill Freeman, and executed by Messrs. Earp, Son & Hobbs has been erected in St. Anne's Church, Turton, which is being enlarged and improved under the direction of Mr. Freeman.

**Mr. David Petch**, architect, of Scarborough, died suddenly on Tuesday morning, it is believed from failure of the heart's action. The deceased gentleman had been connected with the town all his life, and had been the architect for many of the public buildings. He was sixty-six years of age.

**Messrs. T. Baillie & Co.**, of Wardour Street, have been awarded a gold medal for their "Valère Translucid Enamelling on Glass" by the jury of the Cardiff Exhibition.

Papers will be read at next week's meeting of the Royal Archaeological Institute on "The Shrine of St. Fridewide," by Mr. J. P. Harrison; and by Mr. Spurrell, on "The Crossing of the Thames by Plautius," "Hastings' Camp at Shoeburyness," "The Boat Discovered at North Woolwich."

**Professor H. G. Seeley, F.R.S.**, is about to deliver a course of lectures on the practical study of the geology of the country round London. This course is given at the request of students of the London Geological Field Class, and information concerning them may be obtained from Mr. William Dunn, 21 King William Street, Strand, W.C.

**The Council of the Sanitary Institute** can report that nearly five hundred members and associates have been enrolled. The Duke of Northumberland was elected President at the meeting on the 22nd inst.

**The Paris Bourse of Commerce** is to be lighted by electricity, and compressed-air engines will be used for motive power.

**Mr. J. Evelyn Williams** read a paper on "The Witham New Outfall Channel and Improvement Works" at the meeting of the Institution of Civil Engineers on Tuesday. The outlay was 212,000/.

**A Wesleyan Church**, to be erected in Bayswater, at an estimated cost of 5,000/., is suggested as a memorial of the late Sir Wm. McArthur, M.P.

**A Committee** has been appointed to obtain funds for carrying out works of restoration and alteration at St. Peter's Church, Worcester.

**Subscriptions** are being sought for a stained-glass window for the church of St. Mary the Virgin, Oxford, as a memorial of the late Dean of Chichester, who was formerly vicar of that church.

**A Site** has been obtained for building a new Roman Catholic church at Watford, to supersede the present building in Water Lane.

**Mr. Silvanus Trevail**, architect, is a candidate for a seat on the County Council for the eastern division of Truro.

**The Memorial-stone** of the Grand Theatre and Opera House, Halifax, was laid on Wednesday.

**A Bazaar** in aid of the building fund of a church for the new parish of St. Peter, Barnsley, was opened on Wednesday, by the Earl of Wharfedale.

**An "Autumn Market"** was opened in the Leeds town-hall on Wednesday, by the Countess of Harewood, the object being to raise the final 4,000/., required for the Hook Memorial Church.

**The Harbour Commissioners** of Bridlington Quay have decided to build a new landing stage of brick on the north side, on the ground occupied by the ruins of the old wooden pier, which years ago formed the outer pier of the then existing harbour.

TRADE NOTES.

THE operative plumbers of Glasgow and district held their thirty-fifth annual reunion in the Waterloo Rooms, Wellington Street, on Friday evening—Mr. John Speirs presiding—when a large number of members and their friends were present.

THE reports as to the steadiness with which the Tay Bridge withstood the recent gales are confirmed in the strongest manner by the engineer in charge of the bridge. In the report to the railway authorities in Edinburgh he states that the bridge withstood the shocks of the gale without shake or tremble. During the most violent period of the gale, between nine and ten o'clock on the morning of the 16th inst., there was no perceptible difference in the stability of the structure, and even when trains were passing and the wind had all the advantage it could possibly get the bridge stood like a rock.

THE old parish church of Charbury has just been warmed on the small-bore system by Mr. John Neville, of 1 Upper Charles Street, Goswell Road, E.C. The vicar, the Rev. C. F. C. West, writes that, although the church contains 125,000 cubic feet of space, the temperature was raised within two hours after the fire was lighted.

MESSRS. WATERLOW BROS. & LAYTON, Limited, have been awarded a gold medal for their exhibits at the Cardiff International Exhibition.

A SUM of 350*l.* is to be raised for heating the parish church of Quinton, and carrying out works of renovation.

THE Nonpanton Mission Room, Loughborough, has been warmed and ventilated by means of Shorland's patent Manchester stove, supplied by Mr. E. H. Shorland, of Manchester and London, Mr. A. A. Butler, of Loughborough, being the architect of the building.

FROM the report for the year ending September 29 last of the superintendent of the Manchester Fire Brigade, it appears there have been 426 fires, 30 of which were classed as serious, where more than one-sixth of the property was damaged or destroyed. The total loss was estimated at 64,865*l.*, and 1,482,140*l.* was assessed to have been at risk within the walls of the premises on fire. Thirty-seven fires were attended within the limits of the fourteen districts protected by the Corporation fire brigade. At these fires the total loss was estimated at 7,113*l.*, and 103,421*l.* was assessed to have been at risk. As

SOMETHING NEW AND EFFECTIVE.

DRUMMOND'S NEW PATENT PRISMATIC ROLLED GLASS

Marks an entirely new era in Glass Roofing, increasing Daylight and excluding Leakage.

For Glazing Windows, Roofs, Partitions, Doors, Stallboards, Pavement Lights, Ship Skylights, Deck Lights, Lamps, &c.

Made in Large Sheets for Cutting to Sizes as the ordinary Rough Glass. Also in Tinted Cathedral, for Church Windows and Screens, giving a rich and dazzling effect that is not attained by any other Glass in the Market.

that the cost of plant for manufacturing water gas at Hawes would be about 1,350*l.*, and about 300*l.* would cover the cost of piping necessary for its distribution. If 500 lights were in operation, he believed that on their principle gas could be supplied at 3*s.* 6*d.* per 1,000 feet. A deputation was appointed by the meeting to go to Leeds Forge and report to a future meeting their opinion on the practical working of water gas.

THE question of compensation for damage sustained by the property-owners of Cradley Heath by extensive subsidence on July 1 has been settled without taking it into court. The proprietors of the colliery responsible for the damage (Messrs. Parsons & Cooper) have agreed to pay 2,500*l.* to the Property-Owners' Committee, and also 200*l.* for legal expenses. This will be divided amongst the owners who suffered damage by the committee. It was estimated that the total damage caused by the subsidence was about 10,000*l.* The Primitive Methodist Chapel at Cradley has also recently been damaged considerably by mining operations, and the owner of the colliery (Mr. Swindell) has paid to the trustees of the chapel 200*l.*, and undertaken to do the cramping necessary for the stability of the building.

THE foundation-stones of new extensive buildings to be erected, at a cost of about 7,000*l.*, in Free School Lane, Lincoln, by the Lincoln Co-operative Society, have been laid.

MR. EDWIN PEAKE, hot-water engineer, of High Street, Fenton, is the manufacturer, as also the inventor and patentee, of an improved system of high-pressure hot-water heating on the small-bore principle. The apparatus consists of a coil of pipes of very small diameter, containing a very small body of water, is subjected to a fierce fire, and the water soon becomes heated to a temperature far beyond boiling-point, at exceedingly high pressure. This thin stream of water is conducted round a building, and is capable of raising sufficient heat in the coldest weather.

#### REGISTRATION OF PLUMBERS.

AT the examination of plumbers for registration on Saturday, at the Guilds' Institute, applicants were present from various parts of London, as well as from towns of Kent and Essex. The examinations embraced tests of joint-making, lead-laying, &c., and a set of questions relating to the qualities of materials, the construction of various forms of house-fittings, and

the principles of sanitation. The examiners were Messrs. C. Hudson, C. T. Millis, J. C. Ashdown, G. Davis, and L. F. Gilbert, the last representing the United Operative Plumbers' Association. One-third only of the applicants succeeded in passing the examination.

#### AMERICAN BLAST-FURNACE PRACTICE.

ON Saturday night a meeting of the South Staffordshire Institute of Iron and Steel Works Managers was held at the Mechanics' Institute, Dudley. Mr. Hudson, of Woodside Iron-works, read a paper on "American Blast-furnace Practice." The author, after referring to the great development of American blast-furnace practice during recent years, the leading and most striking feature of which is the enormous quantity of pig-iron which is being made from individual furnaces, spoke of the disadvantages under which South Staffordshire as an inland area suffered. With heavy railway and canal rates such as the manufacturers have to contend against, economy must be pursued, not only in rolling-mills, but also at blast-furnaces from which these mills derive their supply of pig-iron. He contended that the only hope of maintaining an increased volume of trade rests on the ability to produce cheaply. One important factor of economy is the spreading of fixed charges over a large production. He then proceeded to explain that American rapid blast-furnace practice depends in the main upon three important conditions, viz., rich iron ore, favourable working-lines of construction, and highly compressed air. Analyses of American iron ores were quoted, and it was stated that frequently the charges of ore contained an average of 60 per cent. of iron. In comparing the sections of American furnaces, the most striking feature that presents itself at first sight is that, in comparison with height, the top of the bosh is not nearly so wide as in English practice, while the hearth is much wider. These features give greater area at melting temperature, afford easy descent of materials, and greatly facilitate the proper diffusion of ascending gases. The liability to forming scaffolds is reduced to a minimum. Blast pressures of from 8 lbs. to 10 lbs. per square inch are employed in America against pressures of from 3 lbs. to 5 lbs. in England. Nearly all American furnaces are worked with closed hearths and tin-fires evenly spaced all round. Hot blast from firebrick stoves of the Cowper or Whitwell type is employed, and driven into the furnace through bronze tin-fires placed very much higher

# FIRE! FIRE! FIRE!

## GRIFFITHS' "PYRODENE" FIREPROOFING LIQUID

(NON-POISONOUS).

Transparent Liquid for Rendering Woodwork Uninflammable,

Without altering its appearance, and where Painting is not desired, such as Wooden Fittings in Exhibitions, Churches, Pews, Matchboarding, Theatre Scenes, Wooden Stairs, Joists, Beams, Floors, Factories, Stables, Mills, &c., in fact, Structures of an inflammable nature of all descriptions. Acts as a priming for new Woodwork for Paint or Varnish. Also for rendering Theatrical and Ball Dresses, Curtains, Paper, Felt, Canvas, &c., perfectly uninflammable.

Griffiths' Liquid penetrates the pores of the wood. It lasts as long as the wood itself. It prevents Dry Rot and decay in house timbers. It does not crack, peel, or rub off.

It is perfectly innocuous and free from smell. It will keep any length of time. Any one can apply it. One gallon will cover double that of any other priming.

All Woodwork in new houses should be fireproofed with this liquid, the cost is so trifling in comparison with the preservation of the timber and freedom from risk of fire. If work is desired to be painted afterwards, Griffiths' Pyrodene Paint is best for the purpose.

AND

## GRIFFITHS' "PYRODENE" FIREPROOF PAINT.

READY FOR USE. NON-POISONOUS. ALL COLOURS.

This Paint is manufactured for preservative and decorative purposes equally as for its FIRE-RESISTING qualities. The Fireproof Paint and Fireproofing Liquid is used at some of the principal Theatres in the United Kingdom.

#### RECENT TESTIMONIALS.

From Messrs. MAXWELL & TUKE, Architects, 29 Princess Street, Manchester: December 2*d.*, 1887.

DEAR SIR.—We used your Paints in nearly the whole of the works for the Royal Jubilee Exhibition, and with very satisfactory results.

Yours truly, MAXWELL & TUKE.

To Messrs. Griffiths Bros. & Co., Dashwood House, London, E.C.

From S. C. LOWE & SON, House Decorators, 33 Cavendish Street, Stretford Road, All Saints, Manchester: November 22, 1887.

DEAR SIR.—In reply to your inquiry, we, as one of the contractors for the painting of the Manchester Jubilee Exhibition, which closed on the 10th of this month, have pleasure in stating that both your "Aqual" Paint, and also your "Pyrodene" Fireproof Paint, have given great satisfaction. We found them work easily with a covering power of from 30 to 40 per cent. over ordinary paint. Although applied during intense frost, and having been subjected to an almost tropical summer, followed by the drenching rains of this autumn, they are as fresh in colour and have as firm a grip as when applied, and appear quite unaffected by the nine months' exposure. We consider them, therefore, well adapted for all work in any climate.—Yours truly, S. C. LOWE & SON.

CHEAPER AND MORE DURABLE THAN ORDINARY PAINT.

GRIFFITHS' "PYRODENE" FIREPROOFING COMPANY, Limited,  
4 & 5 DASHWOOD HOUSE, NEW BROAD STREET, E.C., LONDON.

above the floor than in English practice. Furnaces belonging to the Edgar Thompson Company and the North Chicago Rolling-mill Company, and others, were described. The production of pig-iron at the first-named was said to be from 1,800 to 2,000 tons per week, with a fuel consumption of about one ton of coke per ton of pig-iron. The Chicago furnaces produce from 1,400 to 1,500 tons per week, with less than a ton of coke per ton of iron. These furnaces run about two years, and make from 150,000 to 200,000 tons of iron before they are blown out for repairs. The Franklin furnace was also described, the leading feature of which was the remarkably low bosh. The furnace was described as having done very good work on a mixture of anthracite coal and coke as fuel.

#### THE SWEDISH TIMBER TRADE.

A SWEDISH journal states that, in consequence of the unusual number of vessels which have visited the Swedish ports of the Baltic this autumn in search of cargoes, and of the consequent fall in freights, most merchants who are accustomed to warehouse their unsold goods through the winter are taking advantage of the unusual opportunity to ship them at once. A natural result of this has been an increased animation in the timber trade, but it appears that this has already been overdone, and the latest reports from the timber market of the Baltic ports state that things are very quiet again.

#### ENGINEERING AT THE CARDIFF EXHIBITION.

MESSRS. HENRIE H. RAYWARD & CO., engineers, boilermakers, iron and brassfounders, of Cardiff, have a representative show at the Exhibition. Amongst their exhibits are driven-tube wells for obtaining supplies of water not only for temporary purposes, for which they are particularly adapted, such as building, railway construction, ascertaining water-levels for drainage and other works, &c., but for obtaining permanent supplies for houses, farms, villages, breweries, &c. A well driven in the grounds there is 40 feet deep, and is capable of delivering 1,000 gallons of water per hour. The special feature of these wells is the wonderful rapidity with which they may be put down, a well being often driven and pump set to work in an hour or two. The water obtained, too, is usually a great deal purer than that from open wells, as surface water is prevented

from percolating in and contaminating it. In connection with this a number of constant-supply silicated carbon filters are shown, the merits of which are too well known to need description.

#### BOLTON MASTER BUILDERS' ASSOCIATION.

THE annual meeting of the members of this Association was held on Wednesday in last week. Mr. Henry Critchley, president, occupied the chair. Mr. Briscoe, the secretary, read the annual report, as follows:—

The trade during the past year has not been a busy one, and the scarcity of work given out has resulted in diminished profits. The long-looked-for revival in trade has not yet arrived, and consequently the employers feel the continued strain severely. During the past year there has been little to report in respect to any difference between masters and workmen. In the carpenters and joiners' branch a claim to two hours' allowance for "sharpening time" has been made, but as it is not in accordance with the custom of the trade, and is not named in the rules, an interview is sought to be obtained between masters and workmen to discuss the matter. In the plumbing branch the peremptory action of the Bolton Waterworks Committee in seeking to abolish the use of boilers behind the fireplace without the intervention of a cistern, called forth efforts to bring about a check to this unreasonable resolution. To effect that object a circular was issued to each member of the Council, stating the case of the plumbers, and the result was that at the Council meeting the matter was referred back for consideration, and expressions were used by the members of the Council at the unfairness of adopting such a change without notice to enable the plumbers to complete work already in hand. The Employers' Liability Amendment Bill, the Steam Engines (Persons in Charge) Bill, and the Rating of Machinery Bill have been discussed, and a subscription was voted to the National Association towards opposing these Bills. The former Bill was postponed for a time, and the other withdrawn. At the half-yearly meeting of the National Association, held on January 23, at the Builders' Institute, London, this Association was represented by the president, treasurer, and secretary. Particulars of the meeting have already been distributed amongst the members. At the half-yearly meeting of the National Association, held at Liverpool, on July 23, the representatives of this Association were the president, vice-president, treasurer, Mr. Gregson, Mr. Dickin-

# "EMPRESS"

346 EUSTON ROAD,  
LONDON, N.W.

# CURE.

son, and the secretary. The meeting was of a general character. The various questions affecting the trade throughout the country were touched upon, and the report and accounts were submitted and passed. In the evening members were hospitably entertained, and on the following day a special excursion was made up the river and over the works of the Manchester Ship Canal from Eastham to Ellesmere Port. The question of railway wharfage, as referred to in the last report, has not yet resulted in any settlement, the claims of the railway companies being objected to by the timber trade connected with this Association, and recently nothing has been heard further of the matter.

The following members were elected as committee for the ensuing year, viz.:—President, Mr. William Townson; deputy-president, Mr. Henry Critchley; vice-president, Mr. Pryce Weaver; treasurer, Mr. J. Henry Marsden; on the committee, three representatives from each of the following branches of the building trade were also appointed, viz.:—Carpenters and joiners, bricklayers, plumbers, slaters, plasterers and painters, and masons. Messrs. James Gregson and George Norris were appointed auditors for the ensuing year. The annual dinner of the Association is to be held in December.

#### THE PLUMBERS' COMPANY.

THE Master, Wardens, and Court of the Worshipful Company of Plumbers entertained on Monday evening the Lord Mayor and the Sheriffs, together with a select company, at a Livery dinner, at the Saddlers' Hall, Cheapside. Mr. W. H. Bishop (the master) presided, and amongst the company, which numbered about 120 gentlemen, were the Earl of Denbigh, Sir M. E. Grant-Duff, Sir R. Fowler, M.P., Sir Hugh Owen, Captain Colomb, M.P., Mr. C. Murdoch, M.P., Sir Andrew Clark, Sir Reginald Hanson, Sir E. Arnold, Sir Philip Magnus, Sir Douglas Galton, Mr. Digby Seymour, Q.C. (Renter Warden), Mr. Ewan Christian, Mr. Seth Smith, Mr. Clark, and other members of the architectural and engineering professions, Mr. T. Bent, vice-president of the United Operative Plumbers' Association, the Mayors of several towns, and the Sheriffs (Mr. Alderman Gray and Mr. A. J. Newton). The Master proposed the usual loyal toasts, which were drunk with great heartiness. Lord Denbigh responded for the House of Lords, and Sir R. Fowler, M.P., for the House of Commons.

In proposing the health of the Lord Mayor, the Master, who

began by referring to the early history of sanitary science, said that Mr. Ruskin in his beautiful little volume called the "Bible of Amiens," with the wonderful artistic skill of which he was a master, associated with an edifice already beautiful the adornment of his imagination, and asked the question, "Who built this house?" The same thing might be asked of that guild, which dated back 500 years. As to the work of the company in regard of sanitary reform, the Master said in the metropolitan area in the period between 1854 and 1864 the increase of houses was 88,112; 1864 to 1874 it was 141,472, and 1874 to 1884 it was 190,841. In the period from 1854 to 1864 there were 28 new houses built every day, from 1864 to 1874 45 houses, and from 1874 to 1884 60 houses. At such a rate of increase as that, what was the need of sanitary and other arrangements connected with the water-supply and the health of this vast city? It was impossible to read the report of the Congress of London and Provincial Plumbers of 1884 without being convinced that in the belief of the plumber his work was not being carried out efficiently, and now they had a union of three interests—the general public, the master plumbers, and the operative plumbers—all working in complete accord. One of those who took part in the Plumbers' Congress struck the right chord when he said the general public, who thought they had just cause of complaint against the plumbing trade, were not aware that they did not design their own work, but were in reality carrying out other people's ideas of sanitation, which were not deserving of the name of ideas. The Congress also decided that in its opinion the registration of master plumbers and journeymen was expedient. In 1886 that company opened a list for the registration of plumbers. In the session 1886-7 they had 580 applicants; 1887-8, 730; and in the current session 2,740, of which about 1,000 were received since July. Many facts pointed to the need of such a system of registration. It might be interesting to the Lord Mayor to know that in some of the examinations as many as 75 per cent. of the applicants had failed to pass. At the present time district councils in connection with the Plumbers' Company were in operation in Northumberland, Durham, Cumberland, Westmoreland, the North Riding, Liverpool, Birkenhead, West Lancashire, Cheshire, Denbigh, Flint, Carnarvon, Anglesea, Manchester, and Sussex. In Scotland there were district councils in Glasgow, Edinburgh, Forfarshire, Fifeshire, Aberdeenshire, Inverness, Dumfriesshire, Wigtownshire, and Kircudbrightshire. District

councils were also in process of formation at Portsmouth, Southampton (for Hampshire and the Isle of Wight), Cardiff and South Wales, Bristol and the West of England, Plymouth, Devonport, Leicester, Nottingham, Hull, Leeds, Dublin, and Belfast. He had just had placed in his hand a statement of great importance to them, that it was intended in all future buildings on the Grosvenor estate only to employ registered plumbers. In proposing "The Health of the Lord Mayor," he said they looked to his lordship as the chief representative of our municipal institutions for encouragement and support. The Lord Mayor, in reply, observed that the great want of the present day was more perfect sanitation; and he ventured to believe that if the Plumbers' Company were supported, as they deserved to be, in their present efforts by the other rich companies, they would effect, in the long run, a great improvement in sanitation. Other toasts followed.

#### MORTARS AND CONCRETES.\*

Up to the middle of the eighteenth century, puzzolanas, imported from Italy and France, from Germany *via* Holland, were the standard ingredients for hydraulic mortar in England. About 1756 the Eddystone lighthouse was consumed by fire. John Smeaton, entrusted with the erection of a new structure, searched for native materials for a mortar which was to resist the action of surf and sea. The lime from Aberthaw answered his purpose best. He investigated the cause, and proved before long that but those limes resist the water which, when treated with acids, leave argillaceous residues.

In the year 1796, Parker introduced a product burned of lumps of chalky clay from the English coast, and called it Roman cement, because its colour resembled Roman puzzolana. The inference followed that hydraulic cements might be produced artificially of lime and clay. Consistent efforts revealed to M. Vicat, the French chemist, the due combining proportions and temperatures of calcining for a hydraulic cement which was, about the same time, empirically invented by Joseph Apsidin, an English mason. After trials with waste clinkers, under Parker's process, he pulverised the calcareous detritus produced by the wear of the limestone roads near Leeds, mixed clay with it, and burned it in a kiln, at red heat. He

\* From a paper by Mr. Adolph Cluss, architect, read at a convention of the American Institute of Architects.

called it Portland cement, since it resembled the Portland stone in colour.

About the year 1827, Sir Charles Pasley, a conscientious investigator, improved and cheapened Apsidin's process by selecting the English chalk, an uncrystalline, fine-grained, earthy, porous limestone, of little cohesion, as best suited for manufacturing the cement. He mixed it with clay from the deposits at the mouth of the Medway river, near Chatham, and calcined them. The special merits of calcination at white heat were then not known, so that quality could not be relied upon.

In the year 1828, Professor Fuchs, of Munich, formulated the first scientific theory of the action of hydraulic limes, and proved in a prize essay that Portland cement, which, so far, had been a secret of a few manufacturers, might be produced anywhere, from a variety of materials. For want of successful competition, the manufacture was carried on empirically for many years more; hence the cement lacked uniform quality, the elements of progress, and brought but low prices. Many wrecks are of record where Portland cement had acted mischievously, so that engineers and architects had no confidence in it, on account of supposed treacherous qualities. The new material dragged along with scanty recognition until, in 1858, John Grant, by experiments and adherence to a system of details, enabled the London drainage works and the Thames Embankment to be carried on, unerringly, as to good quality of the cement. The standard was now gradually raised and reduced; but this pioneer's experiments were of necessity incomplete. Owing to local causes, it appeared that by adding to the weight of the cement, its tensile strength was largely increased. From this, unfortunately, the basis was reduced, that great weight was more desirable than fine grinding.

Grant's merits and high standing caused his dictum to remain unquestioned long after experiments had pointed it out as a fallacy. The labour of Reid, Mann, Newman and others in England; Michaelis, Banschinger, Dyckerhoff, &c., in Germany; of Zurek and Hanenschild in Austria, and the valuable tests of the late General Gilmore, U. S. E.; W. W. Maclay, Eng. of the N.Y. depot of docks, 7,000 tests; Eliot C. Clarke, of the Boston Main Drainage Works, 25,000 tests; E. J. Desmith, of Washington, and others have reversed the fallacious doctrines. The importance of fineness is recognised, and we command brands of uniform quality, which equal the strength of good building stone.

In the interesting annals of the material, each successful new factory may be claimed as a triumph of modern science,

because a great variety of raw materials produced an approximately equal quality of cement, provided that each is individually treated and mixed. Still the chemistry of the silicates is yet undeveloped. The observations and conclusions of leading experts conflict sometimes, and neither contestant may be in a position to adduce strict proofs. I have therefore endeavoured to condense from the scattered information such largely accepted facts and theories as tend to direct the attention of the busy architect to the vital points at issue.

*Ingredients, Classifications and Properties of Mortar.*

The principal ingredients of rich mortars, the cementing substances and carriers of plasticity required for the setting of hydraulic mortars and cements, are the limes. The dense limestones, fine-grained, crystalline rocks, chemically called carbonates of lime, form the standard material for the mortar industry. By calcining different limestones, rich or fat limes, hydraulic limes and cements are obtained. In modern practice pure lime mortars are considered as secondary building materials of scanty resistibility formed under unfavourable conditions. Normal mortars are to contain combinations of lime with silica and other bases, approaching the strength of bricks and stones; these rank as primary materials of construction. Good mortar is to have plasticity when mixed with large doses of sand and after solidification compressive strength; tensile strength, as evidence of independent cohesion and force to defy frost and heat; adhesive power for cementing blocks to monolithic bodies. It is to be invariable in volume during and after solidification, to be weather proof, and for hydraulic works also water tight. All mortars are generally mixed with sand. It imparts crushing strength, lessens shrinkage and saves expense in lime mortars.

Hydraulic cements require sand only at exposed surfaces. Otherwise it serves as an adulteration for reducing a surplus of strength and density to actual requirements of a given bulk. The sand should be clean, sharp, large grained, not too uniform in size, free from loam, well screened, and, if necessary, washed. Admixed particles of clay adhere to the sand and form diaphragms between sand and mortar, which for durability require close contact. Puzzolanas are pulverised volcanic rocks, composed chiefly of soluble silica, alumina, iron, and small quantities of lime. They produce hydraulic mortars when mixed with lime instead of ordinary sand. Where better material is scarce, pulverised bricks and similar materials form weak artificial puzzolanas.

Since sand is mostly used in greater quantities than the cementing substances, it equals them in importance. It is in all cases embedded in the matrix as a mechanical mixture. Tensile and crushing strength of the same cement with equal doses of different qualities of sand vary more than those of different brands of cement, within the same group, do among themselves. In slacking limes or mixing cements, a certain quantity of water must form, with the solids, chemical combinations called hydrates. An additional quantity is necessary for imparting plasticity to the paste, and evaporates again during the hardening, hence a too lavish use of water renders the mortars porous. Clear rain or river water is best suited, since waters from wells or springs is often impregnated with carbonic acid or other deleterious substances. Natural cements require more water than Portland, fine ground more than coarse, and quick-setting more than slow-setting cements.

The lime mortars solidify by evaporation and pressure. Induration proceeds slowly from the surface inward. The cement mortars enter the chemical combinations promptly, in proportion to and with the energy depending upon the materials which are already formed by the process. They set by a physical and chemical process, while reaction begun by the agency of heat is perfected by the action of the mortar. As soon as the combinations are accomplished, creative activity is confined to secondary formations. Induration goes on at once simultaneously through the whole mass, but hardens, and strength increases for variable periods. An often mooted question related to the subject under discussion may here be alluded to, Is it safe to use cement on the second set? Cement having set before use in the pan or on the mortar board is probably not damaged chemically when plasticity is restored by new additions of water, but its density will be lessened, and, in consequence, its efficiency. However, for a day or so, as long as the water has not been evaporated or absorbed, these bad effects may be obviated by simply beating, manipulating and stirring the congealed mortar with a minimum of water, when a mortar of little hydraulic energy, but slow and sure increase of density, will finally result. Extra exertion on the part of the mortar men is indispensable for the success of this makeshift. Shrinking mortars are and have been prolific sources of disasters in walls faced with thin jointed materials and backed with material having heavy mortar joints.

The adhesive or cementing power with masonry is a most important requisite of mortar. Until lately this was and is still largely the dark horse of the mortar theories. Mann has asce

tained, by 1,200 special tests, that pure Portland cement of 425 pounds tensile and 5,600 pounds compressive strength per square inch has but 60 to 80 pounds adhesive strength to limestone, and that the proportion of tensile to adhesive strength varies from 9:1 to 5:1. In fact, these are different things which bear no comparison, while tensile and compressive strength being based upon physical attraction between homogeneous molecules, the adhesive power is formulated under a different physical law. Hanenschild has for years investigated it, and finds that it is largely based upon the adhesion of contiguous surfaces, intensified by an intermediate moistening fluid of glutinous consistency, which brings about the transition from apparent to real adhesion. With absolute tight contact, the resistance to separation would be infinitely great; it decreases with the square of the distance between the surfaces, and differs in tensile for heterogeneous plates of equal weights and sizes, or for dissimilar liquids. Both fat lime mortar, as well as Portland cement mortar, resemble glutinous substances, but under the microscope the first shows an emulsion of minute swelled, moistened globules in partial solution; while the second appears as a mixture of semi-vitreous swelled scales separated by water.

#### Natural Cements.

Limestone with intimate, fine-grained admixture of silica, alumina, magnesia, &c., in quantities of 35 to 60 per cent., is called cement stone. The high percentage of silicates causes a separation of the alumina from the silica during calcination at red heat just sufficient to expel the carbonic acid. Oxides of iron and chlorites of potash are generally present in small quantities; they assist hydraulicity and crystallisation. A cement of porous, friable, globular texture, with a specific gravity of 2.7 is obtained; it contains silica and alumina in soluble state, and hence the lime can easily act on either, according to affinity, when water is added for mixing and hydration. The burned lumps must be pulverised before they will combine with water, when they form hydrated silicate of lime, while the alumina remains practically inert. These cements do not heat up nor swell sensibly whilst they are mixed; they set quickly, but harden slowly under water without shrinking, and attain gradually great strength with well developed adhesive force. The colour of these cements gives no clue to their actual value, since it is chiefly due to oxides of iron and manganese, which bear no relation to hydraulic properties.

To insure efficient chemical action in hardening, the grinding

must be carried to the production of impalpable powder. These cements bear doses of sand of double their own volume or over. Mixing pure cements, from 30 to 40 per cent. of water must be added.

Many causes co-operate in affecting rocks of the compound character, required for the production of hydraulic cements. Deleterious material is disseminated through the various strata of a quarry in constantly and widely changing proportions; each stratum exhibits heterogeneous features, hence it taxes judgment begotten of large experience, honesty, carefulness and skill to keep up reasonable uniform quality. Different quarries show dissimilar stones; the best brands vary greatly in chemical composition. Fineness, density, thorough and homogeneous mixture, humidity, accessory ingredients, enter largely in the problems. To preserve the activity and strength of the natural cements for a longer time, air and moisture must be excluded by careful packing and dry storage of the barrels, otherwise the premature production of carbonate of lime will interfere with subsequent hydration.

#### Natural Portland Cement.

Natural Portland cements are manufactured in those rare cases where rocks are traced which contain combinations of lime and silicate of alumina in the chemical proportions and physical conditions found necessary for producing artificial Portland. The treatment then differs from that of ordinary cement only in the higher temperature for burning. There are extensive works of this class around Perlmoos in Germany, Grenoble in France, &c.

#### Artificial Portland Cement.

Most of the progressive governments and organised bodies of architects and engineers of the world have been, within the last decade, taking action on the material. The artificial Portland cement of commerce is a product in which pulverised chalk or limestone is intimately mixed with such a quantity of pulverised clay as will produce, when calcined at white heat, vitreous but not entirely melted clinkers, which, when pulverised and hydrated, harden under water. Being entirely under the control of the manufacturers, the Portland cements are less variable than the natural cement.

According to Dr. Michaelis, the foremost cement expert now living, the raw materials, when dried at 212 degrees Fahr., consist essentially of 75 to 79 per cent., by weight, of carbonate of lime, and 24 to 29 per cent. of silicate of alumina, clay.

## BEAN'S PATENT DIRECT-ACTING VALVELESS WASTE-PREVENTING CISTERNS.

These Waste-Preventers are simple in construction and rapid and powerful in action. The working parts have been improved and are well balanced. The arrangements for charging the siphon are such that a slight pull by hand is all that is necessary to cause the immediate and automatic discharge of the contents of the Cistern.

THE CHIEF ADVANTAGES are—(1) the direct-acting method of charging the siphon, by which the full flush is obtained at once; (2) simplicity of construction; (3) no valve in the bottom of the cistern to cause leakage; (4) no tight-fitting parts to corrode or get out of order; (5) no waste incurred by fastening the "pull"; (6) insures a rapid and regulated flush without holding down the pull.

SOLE MAKERS—

PRICES AND PARTICULARS ON APPLICATION.

**J. TYLOR & SONS,**  
SANITARY AND HYDRAULIC ENGINEERS AND BRASSFOUNDERS,  
2 NEWGATE STREET, LONDON, E.C.

These, when burned, represent 62½ to 67 per cent. of lime and 33½ to 29 per cent. of silicates, silica, alumina, oxide of iron, leaving 4 per cent. for accessories. After the hardening of the hydrated cement a transformation by complicated reaction has taken place into hydrates, silicate of lime as the most important ingredient in hydrated aluminate of lime, ferruginous lime, hydrate of lime, basic sulphate of lime and carbonate of lime. Microscopic examinations of other investigators do not conflict with this analysis. During the calcination, alumina and oxide of iron, which acted in the clay as bases, assume the rôle of acids towards the lime, the calcinated oxide of iron acting as flint in the fire. A preponderance of alumina favours quick setting, while an increase of iron has the opposite effect. The ingredients being pulverised are mixed into a homogeneous paste, baled, dried and burned by exposure to a quick white heat, equal to the melting-point of wrought-iron. This causes, first, the expulsion of the chemically bound water and carbonic acid, and next a softening of the whole mixture.

When partial vitrification sets in, the heat is to be promptly stopped, since a higher heat or a continued, oxidising heat of the normal temperature will ruin the cement, which now requires rapid cooling as much as it did a quick heat before. At this stage the sifting lime is allayed with the softened clay, while neither is in fusion yet. A disposition for the formation of new combinations of lime, with silica, alumina, oxide of iron, &c., is induced without allowing these nascent combinations to be fully consummated, because they, as crystalline bodies, would impede the subsequent hydration and the dense interlocking of the molecules during the setting, crystallisation, of the cement. Under these circumstances the lime, though not chemically combined, is engaged and kept out of harm's way. The high temperature in the kiln has gradually condensed the mass, and most prominently the silica. The globular texture attained in moderate heat was simultaneously transformed into a limited semi-vitreous texture. The Portland cement owes its high reputation largely to such physical changes. Globular texture makes contact by points, while laminated texture achieves more intimate contact by surfaces. In our case it secures in strata of equal height about 50 per cent. more cementing substance than a mass of globular particles. This close packing intensifies cohesion of which the high tensile strength is the brochant. After cooling, the clinkers are ground to impalpable dense, drossy, steel-hard powder, having a specific gravity of 3.0 to 3.15. A few weeks' storage seasons the product and makes it ready for use.

#### Setting and Hardening Processes.

All the combinations produced during calcination contain more lime than can be disposed of, for the formation of hydrates, when the cement is mixed. Hence, under the influence of water, decomposition sets in, combinations are formed which are poorer in lime, and lime is disengaged which, in the presence of alkalies, soda and potash, crystallises to some extent. In the hardening cement there is not any combination of lime which is insoluble in water. The durability of hydraulic cements in water, and prominently in the sea, is not caused by their chemical composition, but by physical properties mentioned above, and in addition by part of the liberated lime absorbing eagerly carbonic acid from the atmosphere, and forming insoluble carbonate of lime which makes a protecting coat over the surface of the cement, and counteracts the decomposing tendencies of the water. Under the influences the texture of the cement is sufficiently condensed for debarring access into the interior of the wells to the carbonic acid itself which, when moist, would act on all the calcareous combinations with silica, alumina and iron. As accessory ingredients occur in Portland cement, sulphate of lime and other combinations of sulphur which, combining with seven chemical equivalents of water, and even more, cause considerable increase of volume.

This explains why a large percentage of sulphuric acid endangers the durability of hydraulic cements, while a small addition of it tends to increase their strength. If the contents of clay in Portland cement rise above 50 per cent. of the calcined lime, overlaid cement, complete vitrification is to be feared during the burning, the lack of cementing substance, lime, is felt, and the cement becomes an inert mass unfit for use. On the other hand, an overlimed cement tends toward quick-setting and blowing or expansion. These efforts, due to presence of free caustic lime, may be remedied by airing such cement, for a day or more, when the caustic lime will absorb carbonic acid from the air and become an indifferent body for the cement. There is for each material one most favourable position in which the tendencies to shrinking and to blowing neutralise each other so that a good cement is the result. The chemical reaction requires, for cements burned at white heat only, half as much water as those burned at moderate heat; this, no doubt, contributes to the superior strength of the Portland. Water, 20 to 25 per cent. of the weight of the cement, generally suffices for mixing pure cement. Mixtures with sand, according to its dry or moist state, require increased quantities.

## VOLUME XXXIX. OF THE ARCHITECT.

Handsomely bound in Cloth, Gilt Lettered. Price 12s. 6d. Office: 175 Strand, London, W.C.

By far the strongest mortar, with or without sand, results from mixtures in a state of incoherent dampness with no more plasticity than absolutely necessary for the work in hand. Too long continued stirring, or excess of water, prevent setting, a paste being formed which slowly hardens by shrinkage, caused by evaporation and pressure, analogous to fat lime. Normal material and treatment result in slow and cool setting, but comparatively low adhesive power.

The strength increases for a slow-setting cement gradually for about two years, while the comprehensive strength increases for many years. All Portland cements bear very large doses of sand. These gradually retard setting and reduce the tensile strength of pure cement, one year after mixing, for 1, 2, 3 and 4 parts of sand to 1 of cement, by 25, 50, 60 and 70 per cent., Michaelis's and Grant's tests. Excessive doses of sand make a hard, raw mixture difficult of manipulation, hence become unsuitable for architectural work. Portland cement is dangerous for use in fastening projecting blocks or ornaments to walls. The fat cement mortars shrink on exposure to air. In addition the silica, the texture of which was condensed by the extreme kiln heat, expands within the mass during the hardening process, and as a consequence drops of water are observed to be pressed out of the pores of the mortar. The cement, then, frequently separates from the surface which it had cemented before, especially if they consist of very dense stones, like granite and marble. Michaelis has followed up this mischievous tendency minutely.

#### *Colour of the Portland Cement.*

Silicate and aluminate of lime are white. This ground colour is covered by coloured combination, in which the vitrification is effected. Well Portland cements have a greenish brown colour, caused by dark brown ferruginous lime, and the intensively green manganese salts. Weaker burned cements appear greenish green, because this ground colour is but partly covered. Admixed sulphates occasionally cause yellow, reddish and green colour. The properties of Portland cement are often misleading. Light weight may be caused by laudable fine grinding or by objectionable weak burning. As a consequence of such dilemmas, J. Newman writes, in 1887, "specifications of Portland cement at present still differ as much as 300 per cent. in requirements as to fineness, 18 per cent. as to weight and 100 per cent. as to strength." The tact and intelligent observation required for obtaining reliable tests, have led to the adoption of standard rules by the German architects and engineers in 1877

These were substantially endorsed by the German Government in 1878, and afterwards by Australia, France, Sweden, Russia, Belgium and Switzerland, and made the basis of recommendations by the Society of Civil Engineers of the United States in 1885, and revised anew by the German Government in 1887. The latest phase of these tests may well be alluded to. They are for general use mechanically, relating to weight, fineness, setting, invariableness of volume and strength, leaving the important microscopic examination of thin sections showing the texture, of chemical analysis and of adhesive power reversed for test cases.

#### *Cement Tests.*

The weight of Portland cement varies from seventy to ninety-two pounds per cubic foot for brands of equally good quality. Since we buy by weight, it is immaterial what size the manufacturer must give to a barrel in order to bring it to the standard gross weight of 400 pounds, but each factory should be held to uniform weight of its output, the extreme differences not to exceed two per centum loss by leakage. Finest grinding of the whole mass coming from the kiln, and not merely fine sifting with a large percentage of granular residue on the sieve, is very important. All the granular residues, even on the finest silk sieves, have practically no setting power, and act little better than good sand. They represent the well burned clinker which did not yield to the action of the millstones as readily as the softer pieces. Finely ground cements have largely increased values for mixtures with sand. The new German regulations allow a residue of 10 per centum on a sieve of 13,000 meshes per square inch. Cements which set in less than half an hour are called quick-setting, and those which do not set before two hours are called slow-setting. These distinct provisions prevent misunderstandings as to what is meant by a slow-setting cement.

Excepting special cases, slow-setting cements, as most trustworthy, and best suited, must be specified for all works in architecture. According to the prevailing American needle test of Gilmore, cement begins to set when it bears a wire of 1-12 inch in diameter loaded with  $\frac{1}{4}$  pound; and it has set when it bears a needle with flat end, of 1-24 inch diameter, loaded with one pound, without making any impression on a flat cake of cement. Whether the volume of the cement has altered during or after setting, is ascertained by immersing in water a thin cake spread upon a glass plate.

Signs of crumbling or cracking at the edges indicate expansion. Fissures in the centre of the cake arise generally

from premature exposure to draughts or sun heat, which cause shrinkage. The cementing power of Portland cement shall be ascertained by a mixture of sand and cement, as used in actual work, since reasoning from tests on the comparative value of different cements for mortar is unavailable. A most interesting instance is presented by tests made by the Association of Civil Engineers of Prussia, at Bonn. Pure cement gave, after 28 days, 426 lbs., and after six years, 556 lbs. tensile strength. One volume of same cement mixed with three parts of sand gave, after 28 days, 170 lbs., and after 6 years, 720 lbs. Average tensile strength, 160 lbs. more than the high figure for pure cement. For all mortar or cement tests, sands of equal size, quality and condition must be used for obtaining comparative figures. This is done by washing and drying quartz sand, removing the coarsest parts by a No. 20 sieve, 400 meshes to the square inch, and the finest particles by a No. 30 sieve, 900 meshes. Tensile strength has been generally used of late years as the convenient gauge for resistance to other strains. Though these relations are not uniform for different cements, it should be upheld as the expression of the cohesion of the mortar. The German regulations have restored that as the leading test for compressive strength. They require slow-setting Portland cement, mixed in the proportion of one part, by weight, to three parts of regulation sand, to have a minimum tensile strength of 230 lbs and compressive strength of 2,800 lbs. per square inch, after twenty-eight days' exposure—one day in the air and twenty-seven days under water. It is a grave error to require on works above the water level a too high tensile strength at an early day. Hydraulic quickness for exposure to the atmosphere is obtained at the expense of durability, while moderate strength and gradual increase with age are to be encouraged. Maclay continued to test cement rejected under the seven days' test. It overtook the accepted cement after a fortnight, and after eighteen months the advantage gained was kept up, 487 against 439 being the ultimate figures of strength. The strength of the cement increases from 35 to 40 per cent. in the interval between seven and twenty-eight days after mixing. The proportion between tensile and compressive strength, and between seven and twenty-eight days, having been ascertained for a brand—new cargoes received during the season—may be controlled by the tensile test, after seven days' exposure for adhesive strength. There are no new data, Mr. Grant found, for a mortar of 1½ of sand, after twenty-six days at 15 to 30 lbs. per square inch.

The properties of Portland cement, as enlarged upon,

characterise it as an excellent building material, especially useful in hydraulic architecture and important works where heavy strains must be withstood within a few days or weeks after they have been built. At high places where no difficulties from water are met and the load is but slowly and gradually imposed, reliable, slow-setting, natural cements are competent competitors to the Portland, since a breaking weight of 300 lbs., attained by the latter in a week, is by the better class of them approached within a year, so that a mortar mixed with them is of comparative value to Portland cement mortar, provided that equal care has been used in either case.

#### Mixtures of Cement.

Mr. Clarke, Boston, tested Portland cement mortar, mixed in the proportion of 1 : 3, and also Rosendale cement in proportion 1 : 1. One year after mixture he found the tensile strength of each to be 256 lbs. A richer natural cement mortar was equal to the weaker Portland cement mortar. He also mixed one-half part of Rosendale cement and one-half part of Portland cement with two parts of sand, and obtained, after one year, 273 lbs. tensile strength, while the same cements, separately mixed, gave for Rosendale, 1 : 2—180 lbs., and Portland, 1 : 2—323 lbs., the average being 251 lbs. Hence, the mixture showed a small gain, probably caused by increased density, in consequence of mixing cements of different texture. Consequently, mixtures of natural and Portland cements are unobjectionable and safe.

#### Mixtures of Cement, Lime, &c.

Superior strength, capacities for sand and hydraulic qualities, characterise Portland cement, but the adhesive power to brick and stone is but developed in lime mortar. It has long been an American practice to re-enforce ordinary lime mortar by additions of natural cements. Strength and hydraulic qualities are added to the solid adhesive qualities and durability of good lime mortar. Under competent management success has followed these mechanical mixtures resembling hydraulic limes, like the imported popular lime De Theil. Similar results have been lately obtained on the new frontier fortifications of the German Empire. Portland cement mortar containing doses of sand is mixed with lime paste. Large increases of adhesive power to bricks, and even small increases of strength resulted. The explanation appears to be because a small quantity of the strong material resists the tensile and crushing strains, hence the addition of large doses of sand.

## Wilson's Patent Dioptrical Pavement Lights.

WILSON & CO. beg to call the attention of Architects and others to the superiority of Wilson's Patent Dioptrical Lenses for pavement and floor lights. These Lenses are constructed on strictly scientific principles, and have been approved by some of the highest authorities on Light. They are made of the Best English White Flint Glass of high refractive power, and transmit more light than any other form of lens yet introduced. The reflecting surface being spherical, the rays of light are distributed in every direction.

Wilson's  
Patent Lenses  
for  
Floor Lights,  
Deck Lights,  
and  
Pavement  
lights  
of every  
description.  
Sample Lenses

Plates.  
Plans, Prices  
and Estimates  
Free.

Fig. 1 shows how the ordinary prism or semi-prism, by receiving the rays on a plane reflecting surface, throws them forward at one angle only, in parallel lines close to the ceiling.

Fig. 2 represents the Patent Dioptrical Lens, and shows by comparison how the rays of light, striking on the curved inner surface, are reflected forward through the face of the lens in every direction, filling the whole angle of 90°, thus illuminating the apartment from floor to ceiling and from wall to wall.

From the above diagram it will be seen wherein consists the advantages claimed for Wilson's Patent Lenses. The objection to the semi-prism is that it reflects the light, as shown in Fig. 1, at such an angle as to be of little use, and more especially if the line of the ceiling in below the line of the pavement; then the value of the semi-prism as a light projector is entirely lost.

It will be seen also, on reference to the above diagrams, in Fig. 1 that the first row of semi-prisms obstructs the rays of light from each succeeding row, whereas in Fig. 2 the bulk of the rays of light are projected at such angles as to pass unobstructed into the room.

The correctness of these illustrations can be practically demonstrated to any architect desirous of testing them.

PRICE LISTS AND ESTIMATES ON APPLICATION TO

WILSON & CO., Bridge House, 181 Queen Victoria Street, London, E.C.

But to be of use as a mortar, this diluted mixture lacks power for cementing bricks together, and this is economically and well increased by lime paste. Provided that the total amount of the mortar substances is large enough to fill the voids of the sand, the added lime serves to fill the still considerable interstices between the particles of cement. This gives higher density—the greatest strength possible with the large dose of sand, and is important for architectural work.

The special requirements of the best mortars for architectural work have not been brought out yet with efficient force. In the mixtures of lime paste with the natural and artificial cements the true solution will be found most likely, because they permit to approach in grade and intensity the slow and steady action of the hydraulic limes, which make excellent material for works exposed to the atmosphere, though they are of limited importance for hydraulic engineering.

Dr. Michaelis writes:—"It has been overlooked of late that water is the element in which the hydraulic mortars develop their full efficiency." All hydraulic cements require for their preservation protection against desiccation, hence moisture. Such cements as consist substantially of hydrated silicates of lime alone act well under water, but when exposed to the atmosphere they are acted upon by carbonic acid, when carbonate of lime, an insoluble body, is formed, an action accompanied by considerable shrinkage, causing minute fissures, which must end, sooner or later, with destruction with atmospheric influence.

#### Concrete.

Concrete is case masonry made of mortar without artificial bond, into which pebbles and broken stone, or similar material, are embedded, in order to reduce the consumption of mortar. The lime or cement acts as the principal material of construction; the coarse, inert accessories are called aggregates on ballast. The strength of concrete depends upon the cohesion of the mortar, adhesive to the aggregate, irregular bonding or interlocking of the coarser fragments, and upon the strength and proportion of each ingredient. Rough, coarse-grained, clean sand is best. Maclay found 11 per centum decrease of strength in Portland cement mortar mixed 1 to 1 of fine sand as compared with coarse sand. With larger doses of sand the loss is greater. To insure compact packing, the ballast consists best of mixture of crushed stone, 1 to 3 inches diameter, and pebbles, which are at least equal to the strength of the mortar. Sun-dried or rain-soaked material is to be strictly avoided. The cementing processes depend upon the use of the concrete.

The finest condition for a solid durable concrete above water is, that it is as dense and homogeneous as possible whilst setting.

Judicious handling of medium quality material may bring out a good concrete, and prevent a dead waste of cement, frequently resorted to to counteract the result of defective manipulation. Concrete has a specific gravity of 1.5 to 2.5, according to its composition of crushed bricks or heaviest stones. A cubic yard weighs from 2,500 to 3,900 pounds. All the voids between the stones need not be filled with mortar. Only enough mortar is required for forming a coherent reticulated film between the coarse ingredients which, by interlacement consequent upon tempering, approach each other in numerous points and surfaces. This secures the necessary frictional stability, without sacrificing the advantage of permeability, or slight porosity, which favours natural ventilation by the diffusion of air through heavy walls. The French architects use air concrete largely for filling in walls of unusual thickness on monuments or ornamented projections of buildings.

For the architect's practice the natural hydraulic lime concretes for use in foundations is an object of importance. It should be water-tight; hence the voids in the larger-sized ingredients must be filled solid by the mass of the mortar, and the latter is, again, to be so constituted that the voids between the grains of sand shall be closely filled by the cement paste.

The addition of water is to be limited to the actual requirements, which fluctuate for natural cements between 50 and 55 per cent., and for Portland cement between 40 and 45 per cent. of the weight of the cement used. Plasticity is only to be attained by diligently tempering an apparently dry mass until water appears on the surface. The proportions of this material are to be ascertained by measuring the respective voids. If stones passing through a 2-inch ring, mixed with pebbles, are used, the space between the stones will approximate 28 to 35 per cent., to which an efficient of safety of 15 per cent. ought to be added for obtaining the amount of sand needed. Since concrete work once done cannot be well controlled, it is for the superintendent to watch that this legitimate construction is not overloaded by heavy discounts, chargeable to indifference, carelessness and dishonesty. The voids between the grains of sand will probably amount to 33 per cent.; that is to say, 67 per cent. of the cubic contents to be occupied by the mortar is absorbed by the sand, and 33 per cent. is to be filled in with cement, so that a mortar of one part of cement to two of sand, and no more, is required. A strong, water-tight concrete will

The "PERFECTUM."

## "PERFECTUM."

In London the above are kept in stock by Messrs. GEORGE WRIGHT & Co., 155 Queen Victoria Street, E.C., who will be pleased to show and explain them to Architects and Contractors.

On view at the Cardiff Exhibition, September and October, and at the Ironmonger's and Metal Trades Exhibition, London, November 14 to 24, 1888.

proximate, by volumes, cement, sand, ballast, as 1 : 2 : 5, and fine Portland cement.

This mixture may reach, after two weeks, a compressive strength of 175 tons per square foot. The 8 volumes of material fill finally a space of about 5 and 2 volumes. A weaker compound, not strictly water-tight, would be 1 : 3 : 6, one-half. General Casey tested a Portland cement mixture of 1 : 2 : 7, three of pebbles, and four of broken stone. It was 138 days old, and showed the first crack at 125 tons, and crushed at 155 tons per square foot. This mixture was successfully used for enlarging the foundations of the Washington Monument, which implied transverse strains at the outer ends of the concrete slabs. The maximum pressure upon the ground under this structure is 5 and 4 tons; but since the maximum pressure at the outer edge of the foundation is nearly 10 tons, the concrete immediately underneath may be assigned to be equally loaded.

As for concretes made with natural cements, a mixture 1 : 2 : 4 is used in a portion of the Washington aqueduct extension, nearly four miles in length, where it is subject to a hydraulic proportion pressure of 4 : 4 tons, a water column 140 feet high. For ordinary purposes a mixture of 1 : 2 : 4 : 4, pebbles and stone, with first-class Rosendale cement, used by competent hands, ought to stand, ten days after deposition, a load of 16 to 20 tons per square foot. For practice, the following conclusions are arrived at. A correctly proportioned concrete has fully as much strength as the cement mortar used in mixing it. By diminishing the ballast below the calculated quantity, the cost of the concrete is increased without benefit to the strength. Strength increases for seven months and over by 30 to 40 per cent. Concretes, with weakest mortar, start low, but catch up considerably in time.

#### PATENTS.

*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]*

#### APPLICATIONS FOR PATENTS.

16632. David Jones, for "Closing the proscenium openings of theatres, music-halls, or other buildings so requiring by

means of a wrought-iron framed rigid curtain." November 16, 1888.

16753. Alexander Gray, for "Grinding Portland and Roman cements, and other cements of a similar nature." November 17, 1888.

16774. Burton R. Phillipson, for "The distribution of sewage," which he has named "The terrace system of sewage distribution." November 19, 1888.

16822. John B. Walker, for "Improvements in ovens or gas cooking-ranges." November 20, 1888.

16825. John Ruscoe, for "Improvements in the application of enamel coating on the rims and in the grooves of pulleys." November 20, 1888.

16846. Charles Allen, William Allen, Walter Allen, Jesse Allen, and Frederick Allen, for "Improvements in and apparatus for glazing horticultural and other glazed structures." November 20, 1888.

16860. Wilhelm Doehring, for "Improvements in and relating to plastering, and in the preparation of baths and the like therefor." (Complete specification.) November 20, 1888.

16867. Alfred Julius Boulton, for "Improvements in baking ovens." (Charles Frederick Hubbard, Canada.) November 20, 1888.

16881. William Sparrow, for "An improved method for utilising gas and electricity for illuminating names of railway stations, shop signs, fascias, and trade signs generally." November 20, 1888.

16884. Alexander del Guerre and Demetrius Steffans, for "Improved devices for securing doors." November 20, 1888.

16901. James Smith Naylor, for "Improvements in and appertaining to automatically closing doors, applicable for preventing the spreading of fire in mills, warehouses, or like buildings." (Marshall Tillotson, United States.) November 21, 1888.

16912. Henry Brecknell, for "A straightway valve or cock, as may be termed." November 21, 1888.

16946. James Yate Johnson, for "Improvements in fittings and switches for incandescent electric lamps." (Theodore Mace, United States.) November 21, 1888.

16969. Ephraim Taylor, for "Improvements in holders and shelves to be used in combination with firegrates and ovens for heating and cooking purposes." November 22, 1888.

16975. Thomas Wolstenholme, for "A new or improved apparatus for hanging wall-papers and the like." November 22, 1888.

# THE "THOMAS" LAMP.

Lighting Power with  
ordinary London Sixteen-  
Candle Gas, from tests  
taken by Professor Wm.  
Foster, M.A., L.R.C.S.

No.	
10.	11·4 Candle-power per foot.
11.	12·5           ,,           ,,
12.	12·5           ,,           ,,

These Lamps are made in three  
sizes, Nos. 10, 11, 12.

These Lamps can be obtained through Gasfitters, Ironmongers and  
Merchants. Foreign Orders through Merchants only.

The advantages of this Patent  
over other existing Lamps  
are:—

Small consumption of Gas  
with great Illuminating power.

No possibility of the Burner  
corroding or getting out of  
order, as is the case with other  
generative gas lamps.

The Lamp can be fitted by  
any gasfitter. No fine per-  
forated metal, gauze, or other  
obstructions are used in this  
Patent, as in other lamps which  
are liable to become choked  
through imperfect combustion,  
rendering the lamps smoky and  
useless.

FOR FURTHER PARTICULARS, APPLY TO

**Ridsdale's Railway Lamp & Lighting Company, Ltd.,**  
**55 & 56 MINORIES, LONDON, E.C.**

# The Architect.

## THE WEEK.

ON Monday Mr. HOOPER, the holder of the Godwin Bursary, read a paper at the meeting of the Institute of Architects, when Mr. THOMAS WORTHINGTON occupied the chair. The paper, called "Building Control in Paris," entered minutely into the details of "administration," to use a significant term of Professor KERR in regard of architecture. It was hardly possible to avoid instituting a comparison between London improvements and "how they manage these things abroad," and Mr. WOODWARD, as it were, deprecated adverting to the Metropolitan Board in Mr. BLASHILL's presence. Observing he was sure that Mr. BLASHILL had at heart the interest of the architectural well-being of the metropolis as much as any among them, he went on to ease his mind of grievances which have exercised the minds of others as well as himself. Opportunities of making the improvements to the full effect had been lost. The utility of new streets was sacrificed for the sake of a few feet extra width. But, worst of all, within the last few months the Metropolitan Board had given leave for a building to be erected which should project 38 feet beyond the building-line in the Marylebone Road, contrary to the stipulations of the Act of George II., for the construction of the new street from Islington to Paddington, contrary to the wish of the vestry, and to the destruction of a "magnificent avenue." This should scarcely surprise members of the Institute, who must have some experience of the autocratic methods often employed by the Board. Mr. BLASHILL did not claim to speak except in his capacity of a member of the Institute of Architects, but in a genial fashion he deplored that persons should attempt criticism without knowledge of facts. Mr. WOODWARD's reply, however, shattered Mr. BLASHILL's defence, and he wound up by remarking that that gentleman had been silent on the gravest point—that of allowing the projection of the building over the line, and also that the question whether the Act of George II., which Mr. BLASHILL alleged was repealed in 1855, had been repealed, was still *sub judice*.

THE success of the British Association for the Advancement of Science could not fail to suggest the founding of a similar Society for its furtherance. For at least half a century proposals of the kind have been brought forward. Not until this week could such a Society appear as a reality before the public. Although nothing can be easier than to talk about art, it is no simple task which is before the founders of the National Art Congress. Their experience this week in Liverpool must convince them that the gathering of crowds will not be of much service to art unless something more follows. The chief attraction was taken to be the presence of Mr. ALMA-TADEMA, who was known as the author of a picture which had scandalised many strait-laced people. So many people besieged the room assigned to the section of Painting, it was found necessary to carry off the artist to a theatre where the crowds could be satisfied with gazing on him. An excitement of that sort is contagious, and it is to be hoped Mr. ALMA-TADEMA will not have to be its victim during the ensuing years. It indicates the spirit which induces people to go to congresses. In the British Association the sightseers have become familiarised with the *savants*, and it is necessary to get up supplementary entertainments in order to have the appearance of prosperity which comes from the sale of tickets. The interest which Sir FREDERIC LEIGHTON has taken in the Congress proves that there is a necessity for doing something to make people take more interest in art, and his eloquent address will, we hope, atone for the negligence of the Academy during the greater part of its existence to do anything for art except what was inspired by selfishness.

FOR some weeks it was known that Mr. BURGESS was destined to be the new Academician, and there was only one opinion about his eligibility. Twenty years ago, when

he and Mr. LONG entered on the field which was once JOHN PHILLIP'S, it was prophesied that Mr. BURGESS was to enter first within the Academy. If Mr. LONG had kept to Spanish scenes that might have happened, but happily he was attracted by subjects which gave more scope to his imagination. It is no use now to ask why Mr. BURGESS should have remained so long an Associate. His pictures always showed the hand of a skilled artist. In the Manchester Jubilee Exhibition it was found that he could hold his own against the painter from whom he drew inspiration at one time, and after his success against JOHN PHILLIP his claim to the full honours of the Academy could not be denied.

It is not unlikely that something more will be heard about the deviations from the contracts of the School Board of London. The following is the first resolution which Mr. GOVEN has inscribed on his re-election:—"That it be referred to the special committee on the work of the Works Department to bring up a report as to whether proceedings should be taken against any, and what, contractors who have charged, and been paid, for work not executed, or who have otherwise broken their contracts with the Board." The resolution is an amendment to one standing back for several weeks which Mr. HELBY proposed:—"That, as the report of the special committee upon the work of the Works Department establishes the fact that losses have been sustained by the Board in connection with the building of schools, and as the special committee have been unable to definitely ascertain who are the parties who have profited by these transactions, in the opinion of the Board, a representation of these facts should be made to the Lord President and the Vice-President of the Council, praying them to take such steps to institute a full and searching inquiry into these transactions as they may deem to be necessary." There is much to be said in favour of the original proposition. The special committee have been over lenient, and in the interests of the public an independent inquisition is demanded, and a plainly spoken report.

It was to be expected that the coroner's jury who had to consider the accident at Great Titchfield Street should seize upon anything which seemed to be a definite cause for the subsidence of the building. On Wednesday Mr. APPLETON, a builder, ascribed the accident to the weakness of the 14-inch wall. He said it should have been built in cement instead of mortar. According to this witness the columns in Ridinghouse Street had the heaviest weight to carry and fell first, causing the weight to go on the other columns, and that the wall fell with it. On the other hand, Mr. JENNINGS, the district surveyor, described the work as very good, including the mortar, and said he was not prepared to say what was the cause of the accident. Other witnesses ascribed it to the columns being of inadequate strength. But the jury selected the wall as being the offender, and added the following rider to their verdict of accidental death:—"The said jurors, after hearing the evidence of the experts, are of opinion that the 14-inch wall, built with mortar, was not sufficiently strong to carry the weight of the superstructure, which on a continuous iron bressummer was concentrated upon the column in the centre of the building in Ridinghouse Street, and the jurors consider that this was the cause of the sudden collapse of the building. The jurors consider that such iron columns should have been placed on brick piers built with cement; and further, that the practice of loading the floors of new buildings with materials used for their construction and otherwise should be avoided, as they are likely to cause strains upon the building generally. The jurors are further of opinion that the architect, Mr. MILLER, should, in the exercise of his discretion, have taken greater care in designing such building, so as to insure the stability without risk of any kind; further, that they consider that enlarged and discretionary powers should be conferred on district surveyors, so as to permit of more efficient supervision than they at present possess." This opinion is comprehensive enough. The question now remains about who is to pay for all the damages, and the accident will, we trust, be investigated in a more scientific way.

## THE JOURNAL OF THE GONCOURTS.

ONE of the most curious of modern French works is the "Journal des Goncourt." Although it is not adapted for general circulation, even in France, yet it is likely to be among the books of our time which will be read hereafter. The brothers JULES and EDMOND DE GONCOURT realised SHAKESPEARE'S idea of "an union in partition, two seeming bodies but one heart." Their journal is, they say, the confession of two lives that were inseparable, of two spirits that received identical impressions from things. There is something unique in revelations which have an origin of that kind, for the union of the brothers was different from ordinary literary partnerships. The nearest approach to it in England is represented by the works (mostly unpublished) of SOBIESKI and CHARLES EDWARD STUART. The brothers GONCOURT were not only of one mind in the ordinary sense of the phrase, but both on principle adopted the same theory of literature and art, and devoted themselves to its propaganda with equal energy.

That theory was realism. At present M. ZOLA is generally taken as its representative in literature. But he has testified that the two GONCOURTS and FLAUBERT were its inventors. People sometimes believe that realism is easily produced by men who are ignorant and too slothful to go through the preparations which are necessary with work of a different class. An accusation of that kind will not apply to the GONCOURTS. The historian MICHELET, when writing of their books on the eighteenth century, has described them as learned as well as ingenious. The labours which the two men undertook for the elaboration of a novel seem incredible. Nothing was left to the imagination, and every statement was tested. Believing that in France, if not elsewhere, all action turns on nerves, they have studied that branch of physiology as if they were to write a treatise for experts. A man is always disposed to be vain of knowledge which he has acquired without the aid of teachers, and it must be owned that when the GONCOURTS have to write about any form of hysteria, they become indifferent to the danger of having overmuch of one seasoning. Hysterical men and women may find a strange delight in following descriptions which are like demonstrations in a classroom of anatomy, but out of France the books containing them may be ignored without much loss.

For two men who are skilful in observation and analysis there could not be found a better field than Paris. The GONCOURTS have cultivated it, and it has yielded the journal, as well as other things. The volumes record an experience of about twenty years, that is to say, during almost the whole period of the Second Empire. Their first book appeared on the day which the *coup d'état* made memorable, and the death of JULES GONCOURT, which put an end to the common diary, occurred about a month before the war with Germany began. As a record of many things which will not be found in ordinary histories the journal may one day be prized. But among the uses of the work at the present time is the light it throws upon the principles of many French writers and artists.

The GONCOURTS had their own set of associates, and appear to have been oblivious of many of their contemporaries in literature and art. They could not be reckoned among Bohemians, and seem to have avoided the men who were fighting the battle of realism as painters. There is no mention in the diaries of a meeting with MANET or COURBET, or RIBOT or BONVIN. The diarists might be coarse in language, but they take care to make it felt that they never ceased to be fine gentlemen.

Among the artists the man who appears to have gained most of their esteem was GAVARNI. When they knew him he was subject to what might be called a craze for mathematics, but however he might ramble in his visions the diarists always write about him as if he were one of the greatest men in France. THÉOPHILE GAUTIER held a corresponding position in letters for them.

It is remarkable to find that in a discussion about antique art, GAUTIER, who was a worshipper of the beautiful, if there ever was one, declared that PHIDIAS was *un décadent*. In what sense must be left to the imagination. But still more remarkable is an anecdote of RUDE, the sculptor, which illustrates the same theory. He placed a cast of the great head of the horse from the Parthenon, in the British

Museum, beside the head of a Paris cab horse, and pointed out how the latter was more beautiful than the Greek work. From the contrast he came to the conclusion that the Greeks represented simply what they saw, and were not seekers after the ideal. We can understand the gratification of the GONCOURTS in having the authority of the sculptor of the finest of the groups on the Arc de l'Etoile for their theory. Another sculptor with a belief in realism was CARPEAUX, who afterwards produced the group of the *Dancers*, which stands in front of the Paris Opera House. The journalists record how, in a railway carriage, he explained his theory of aesthetics to them, which consisted in following nature as it appeared. He maintained, also, that as fine models were to be found among the Cent Gardes as those employed by the old Greeks. As for modern Greeks, a Prix de Rome stated that when they modelled it was solely by the aid of engravings, and in Athens neither models nor modelling clay can be found. The GONCOURTS maintain that in Greek art there was neither dream, nor fantasy, nor mystery, nor any of the ideality with which it is endowed by WINCKELMANN and the professors of the French Institut. They point to the torso of the Vatican, which they place at an elevation infinitely above the *Venus de Milo*, as being suggestive of a man who was not fed on ambrosia but on human nature's daily food, and could digest it satisfactorily. The application of the sculptor BARRE for permission to take casts of the two hands of the Princess MATHILDE, in order to impart more life to a statuette he was making, was also an illustration of the value of realism.

The GONCOURTS are hard upon painters like PAUL BAUDRY, who have faith in the traditions of art. For that reason they seem to have avoided exhibitions of pictures unless in one instance. Even with men of their class, the Salon of 1857, coming after the International Exhibition, could hardly fail to excite more than the usual amount of criticism. The question asked by every one was how far the standard of 1855 could be kept up, and after seeing the galleries the majority of the critics were satisfied. France was supposed to have reached a greater height than was possible in the reign of HENRY IV., and there was a disposition to applaud the artists who had upheld the reputation of the country in the international contest. The new sect of Realists fared badly at the time, for the Salon of 1857 was under the control of their enemies, the grandees of the Institut. A writer, who was one of the hangers-on of the court, and who did everything with a view to promotion—EDMOND ABOUT—expressed the official sentiment towards realism, which for some reason was treated as treason in disguise. Judging by ABOUT'S criticisms on the Salon of 1857, realism is a moral infirmity, an epidemic, an epizootic disease, a coalition between fellows who cannot design or write against drawing and orthography, and so on. Now it so happens that the only Salon Exhibition which is noticed in the GONCOURTS' volumes is that of 1857, and their words give us another view of the Exhibition. They describe the artists as an army of seekers after ingenious ideas, and the pictures as literature of the pencil. The ideals were either anacreontic or mythologic, but to be anecdotic was the chief ambition, and a man reached the sublime if he hit on such a subject as *Molière Reading the "Misanthrope" to Ninon de Lenclos*. The road to success was by the drama, the apologue, and whatever was not painting. The GONCOURTS say they would not be surprised to find a printed poster reproduced on canvas, as if it were something *spirituel*. The President of the Academy has denounced a similar spirit as inspiring English pictures. We have often said our painters are only illustrators of subjects taken from books, and yet they are surprised that critics will not take them to be artists with whom execution is everything.

There was one artist with whose work the GONCOURTS might be supposed to have sympathy. Archdeacon FARRAR on Sunday described MILLET, the French painter, as teaching France "the lessons of the true intrinsic grandeur of manhood and of the infinite sanctity of toil." Divines have their own rules of interpretation, which are often incomprehensible to laymen. We must not therefore wonder if the Archdeacon gives a meaning to the pictures which the painter never intended they should

bear, and which is no less amazing to any one who has watched the life of French peasants. The GONCOURTS' explanation of MILLET's work is very different. They express astonishment at the courage of the man who dared to represent what he saw of women from whom feminine beauty had disappeared, who were flattened by labour and misery, and might be called workers without sex. The brothers do not appear to have met MILLET, but his friends told them many things about him. His first drawings were copies of the engravings in his grandmother's prayer-book. His father showed them to a drawing-master in Cherbourg, who said it would be a murder if so promising a boy became a field labourer. The Municipality of Cherbourg granted young MILLET a pension, which enabled him to enter DELAROCHE's atelier. But residence in Paris did not cause him to forget his country ways, and at Barbazon he could work in the fields. His wife was a peasant, and was unable to read or write. When MILLET was absent he corresponded with her by means of marks or signs on paper, which served instead of words.

The French are not great travellers; indeed, we find it stated that GUYS, the draughtsman, said no man ever saw in London a Frenchman who had crossed to see the place, and who spent his money tranquilly like the English in Paris. Frenchmen of that species are no less rare in other cities. It was, therefore, we suppose an important event when MM. GONCOURT packed up their trunks and departed for Germany in company with M. SAINT VICTOR. It must have been a sacrifice on the part of their friend, for he hated all people who did not belong to the Latin race. Their object was to see pictures by French painters of the eighteenth century in order to describe them. Heidelberg reminded them of VICTOR HUGO, whose poems they believed would defy time. In the Dresden Gallery they noted two pictures of their countryman WATTEAU, and nothing else. The frescoes of KAULBACH in Munich appeared to their eyes to be as stupid as a metaphor of the Revolution, but compensation was found in the *Barberini Faun* in the Glyptothek, which is described as being the most admirable translation by the sculptor's art of a humanity that was contemporary with the gods. At Vienna, in the Lichtenstein Gallery, they single out the four works of CHARDIN. They enjoyed the Austrian capital, and confess that Paris appeared grey and dull after it.

Afterwards the three travellers ventured on an expedition to Holland. On seeing the *Night Watch* of REMBRANDT, they say the works of SHAKESPEARE were recalled, for the girl in front, who is so brilliantly clad in what seem to be emeralds and amethysts, and whose cap is of gold, seems to be a type of some of the poet's characters, such as PERDITA. But the work which appeared to be the most marvellous example of the painter's art, the most beautiful picture in the world, is the *Four Syndics* of REMBRANDT.

PAUL DE SAINT VICTOR, whose name is so often mentioned in the volumes, was one of those able writers who are attached to the French press. As a dramatic critic he was influential. But he was always planning books which would give scope for the display of his scholarship and his thoughts. One of them was to be upon the metopes of the Parthenon; but he was afraid that the French language was not rich enough in *vocables religieux* to enable him to do justice to figures in which divinity circulated like blood in mortals. It was characteristic of him to have the walls of his room hung with facsimiles of drawings by the great Italians, and he treated everyday affairs like a man who had descended from a height. But the GONCOURTS considered there was overmuch of the scholar and too little of the observer in his views of life.

In March 1867 the GONCOURTS departed for Rome, mainly for the purpose of imparting local colour to their novel "Madame Gervaisais." There was supposed to be a lack of civilisation in the Rome of that time, but as the travellers were keenly observant they could not help to remark that there was compensation for the absence of discussions over a budget, parliamentary debates, conscriptions, heavy taxation, and other signs of progress and liberty. They were inimical to everything Papal, but they found that the Roman people had the gaiety of their skies, food was cheap, wine was at a nominal price; there was no humiliation in the poverty or bitterness in the misery, and everybody was charitable.

Their visits to the Vatican Museum confirmed their belief in the overwhelming superiority of the Greek sculpture. The value of Greek painting they do not discuss, for, apart from absence of means of information, they seem to have a misgiving about its qualities. Painting, they say, is not drawing; colour should be its chief characteristic; and apparently colour is only to be found in countries where there are fogs—where certain prismatic effects ascend from the water to the air, as in Venice and Holland. Greece, with its clear ether, may not have been more inspiring for colour than Umbria.

The famous fragment of the group of APOLLONIUS, the torso of the Belvedere, is described as being the only example of art in the world which imparts a complete and absolute sensation of a *chef-d'œuvre*. The GONCOURTS say it confirmed them in the idea which was instinctive with them, viz., that the supreme beauty is the exact representation of nature by a genius, and that the ideal, which so many have sought to introduce in art, is always of inferior value to truth. On the other hand, the *Moses* of MICHEL ANGELO, with its gross muscles, its exaggeration of force, its rivers of veins, is declared, when compared with the torso, to be the work of a *décadent* who was no less corrupted than BOUCHER, although one sought to express force and the other grace.

Only one painting in the Vatican finds a notice in the journals. It is RAPHAEL'S *Transfiguration*, and it is described as leaving the disagreeable impression of paper badly painted. The colouring, composition, and sentiment are said to be defective. In fact, the picture is found to be grossly material as a representation of a Scriptural event, prosy and vulgar as a work of art. But RAPHAEL is not one of the divinities of the GONCOURTS. In reporting a meeting where TAINÉ was cross-examined for his statement about the four caryatids of humanity being SHAKESPEARE, DANTE, MICHEL ANGELO, and BEETHOVEN, it is said that somebody asked where was RAPHAEL? The journalists remark that the querist was incompetent to distinguish a work by RAPHAEL from one by REMBRANDT! A man who thought about the Roman painter must thereby be taken as a dunce. In another part we find a shrewd remark about the position of the eyes in an Italian picture being an indication of the age when it was produced. From CIMABUE to the Renaissance, the eyes are placed further apart than in Byzantine works, and, finally, ANDREA DEL SARTO and CORREGGIO follow the precedents of the Greeks, and nature also in fixing the positions of eyes.

VIOLLET-LE-DUC is described in the journal as "le fin et discret observateur," but his observations will not allow of reproduction. His uncle, DELÉCLUZE, who was one of the writers on the *Débats*, related that he went to see the newly-decorated Sainte-Chapelle with his nephew, who exclaimed that a parrot was necessary for the cage, a specimen of ribaldry which was not creditable to an ecclesiastical architect. DELÉCLUZE on that occasion abused the use of polychromy in connection with architecture and sculpture. He maintained that PAUSANIAS does not mention the employment of paint in that way, and the examples in Pompeii belong to a period of decline. Any one who has seen VIOLLET-LE-DUC's freaks in the chapels of Notre Dame and in other buildings will say it is a pity his uncle was not able to exercise a little influence over him.

The GONCOURTS claim to be the founders or the revivers of the taste for Japanese and Chinese nick-nacks. They relate how a description of theirs of a chimney-piece adorned with *bibelots japonais* was supposed to have qualified them for admission to the Charenton madhouse. Art is not, they say, of one time or place, and Japanese art has its beauties as well as the Greek. The Princess MATHILDE was one of the early converts to the new taste, and it is recorded that when the representatives of academicism were dining with her, the Princess startled them by declaring aloud in a violent manner that she preferred a Japanese to an Etruscan vase. The brothers do not, however, bore their readers about their hobby, but any remarks they make upon it are well founded, as when they speak of the peculiar faculty of the Japanese to create monsters, hydras, and chimeras, whilst none of the European artists has succeeded in designing anything more terrible than the one in INGRES' picture.

SAINT-BEUVE, the critic, paid the GONCOURTS the

honour of seeking their acquaintance. On his side he tried to be friendly, but there was no return. Among the features of the journals which will be considered most displeasing are the persistent efforts to belittle the man who in his line was without an equal in France. Even his dolours as an invalid do not move the writers to treat him gently. No one would make out SAINTE-BEUVE to be a hero, but where would Frenchmen be if a good deal of tolerance about their past was not granted? In the course of his intellectual evolutions he had changed sides like a great many of his contemporaries, but why should a man who had to write for a living, and who was only an amateur politician, be punished because he varied in his beliefs, whilst with other men all transformations were excused? JULES JANIN, for example boasted, that the secret of his endurance as a writer was to be found in changing opinions fortnightly. No one could say that at any time SAINTE-BEUVE's writings did not express his thoughts; but if his criticisms happened to be unsatisfactory to some people they were supposed to be venal and inspired by malice. Even the Princess MATHILDE could at that time forget herself, and endeavour to make out the invalid's ingratitude as unpardonable, by describing all the presents which came from Her Highness to him. And the crime consisted in sending articles on literary subjects to a newspaper that was not subsidised by the Government. The GONCOURTS despised SAINTE-BEUVE because his scholarship did not comprise a knowledge of the details of art. He once told them that all he knew about pictures was derived from what VICTOR HUGO said to him in the galleries of the Louvre, and he had forgotten that little. He wished to write an article on his friend GAVARNI, and he asked the brothers to visit him in order to obtain their help. They were horrified when they discovered that he was not acquainted with the technicalities of art, and had not the details of the biographies of obscurities like ABRAHAM BOSSE and FREUDENBERG in his memory. The scholar took notes of what the brothers said, and they considered he was acting the rôle of a robber, and suggest that it was customary with SAINTE-BEUVE to steal his visitor's ideas, notions, and science in order to give value to his articles. In the records of literary quarrels there are strange scenes, but nothing so childish as the vanity of the GONCOURTS in speaking of SAINTE-BEUVE. The passages will make readers believe the brothers were easily led astray by prejudice, and are not to be trusted when they blame or flatter their contemporaries. Their recitals also seem to explain why the GONCOURTS had only one companion among the writers of their own age; the remainder were probably afraid of them.

### THE POSITION OF ART IN ENGLAND.\*

By SIR FREDERICK LEIGHTON, P.R.A.

LADIES AND GENTLEMEN,—I cannot but feel that to some of my hearers, and to not a few of those who do not hear me, but whom the words spoken in this place may chance to reach through the press, some brief explanation is due, at the outset, as to my occupancy of this chair. To them it is known that weighty reasons have for many years compelled me to decline all requests—and those requests have been frequent, urgent, and most gratifying to me in form and spirit—that I should publicly address audiences beyond the walls of Burlington House on the subject which is to occupy this congress—the subject of art. It is not without some compunction that I have followed this course, but the exigencies on the one hand of the duties of my office, and, on the other, a firm purpose, which you will not, I hope, rebuke, to remain always and before all things a working artist, have left to my too limited strength and powers no alternative but that which I have adopted. Nevertheless, I have felt justified in obeying the summons of the founders of this congress, and for this reason, that while the far-reaching character of the effort here initiated and my earnest desire to contribute, in however small a measure, to whatever of good may flow from it, have seemed to make it incumbent on me to accept the duty of saying a few words on this occasion, its comprehensive and national character lift it into a category wholly apart from and outside the sphere of purely local interests, such as those which I had hitherto been invited to support. I trust I shall be pardoned this short obtrusion of private considerations, and that you will see in it not a movement of egotism, but the discharge of a simple debt of courtesy; which said, let me address myself to the task im-

posed upon me—the task of showing cause and need for the existence of the Association which inaugurates to-day its public work, and of arousing, if it is in my power, your efficient sympathy in that work, that it may not remain barren and without fruit.

But here I am at once conscious of a perplexity lurking in your minds. "Why," I hear you ask, "should an organisation have been called into life for the sole purpose of considering in public, matters relating to the development and spread of art in this country? What hitherto unfulfilled ends do you seek to achieve? Do you aim at the wider extension of artistic education in this country? But vast sums from the public purse are annually devoted to its promotion; schools of art multiply, one might almost say swarm, over the face of the land. Or do you tax the great municipal bodies of England with remissness on this score? But day by day efforts in this direction among the great provincial centres of trade and industry become more marked and effectual. No announcement more frequently meets our eyes than that of the opening, with due ceremony and circumstance, and seemingly with full recognition that the event is an important one, of spacious public galleries for the annual exhibition or for the permanent housing of works of contemporary art. Or does art find private individuals lacking in that noble spirit which so often prompts Englishmen to devote to the enjoyment and profit of their fellow citizens a large share of the wealth gained by them in the pursuit of their avocations? But a great gallery of art which rises, hard by, across the road would shame and silence any such assertion. Or, again, can it be denied that what encouragement to artists is afforded by the purchase of innumerable pictures, at all events, was never more liberally meted out to them than within our generation, and does not the crowding of exhibitions, of which the name is legion, evince abundantly the responsive attitude of the country, as far at least as one of the arts is concerned? Are not statues multiplying in our streets? Is not architecture, as an art, finding at this time increasing, if tardy, acceptance at the hands of private individuals? Is not a wholesome sense dawning among us that even a private dwelling should not offend, nay, should conciliate the eye of the passer-by in our public thoroughfares; and, lastly, has not a more than marked improvement taken place within our day in the character of all those intimate domestic surroundings which are the daily diet of our eyes, and should be daily their delight? Are these not facts patent to all, and do they not seem to cut from under your feet the ground on which you seek to stand?"

Yes, all this and more may be said, and I should be blind as an observer, I should be ungrateful as one speaking in the name of artists, did I not recognise the force of these words which I have put into the mouth of an imaginary querist. I acknowledge with joy that there is in all these facts, and still more in their significance, much on which we may justly congratulate ourselves, much that points to a quickening consciousness, a stirring of slumbering æsthetic impulse, a receptive readiness, a growing malleability in the general temper, which promise well; and it is precisely such a condition of things which justifies our hope of good results from this congress, and in it we find our best encouragement.

Well, what then is our charge in respect to the present relation of the country to art? What are the shortcomings for which we are here to seek a remedy? Our charge is that with the great majority of Englishmen the appreciation of art, as art, is blunt, is superficial, is desultory, is spasmodic; that our countrymen have no adequate perception of the place of art as an element of national greatness; that they do not count its achievements among the sources of their national pride; that they do not appreciate its vital importance in the present day to certain branches of national prosperity; that while what is excellent receives from them honour and recognition, what is ignoble and hideous is not detested by them, is indeed accepted and borne with a dull, indifferent acquiescence; that the æsthetic consciousness is not with them a living force, impelling them towards the beautiful, and rebelling against the unsightly. We charge that while a desire to possess works of art, but especially pictures, is very widespread, it is in a large number, perhaps in a majority, of cases not the essential quality of art that has attracted the purchaser to his acquisition, not the emanation of beauty in any one of its innumerable forms, but something outside and wholly independent of art. In a word, there is, we charge, among the many in our country, little consciousness that every product of men's hands claiming to rank as a work of art, be it lofty in its uses and monumental, or lowly and dedicated to humble ends, be it a temple or a palace, the sacred home of prayer or a sovereign's boasted seat, be it a statue or a picture, or any implement or utensil bearing the traces of an artist's thought and the imprint of an artist's finger—there is, I say, little adequate consciousness that each of these works is a work of art only on condition—that is, a work of art exactly in proportion as it contains within itself the precious spark from the Promethean rod, the divine fire-germ of living beauty; and that the presence of this divine germ ennobles and lifts into one and the same family

\* The opening address at the National Art Congress, Liverpool.

every creation which reveals it; for even as the life-sustaining fire which streams out in splendour from the sun's molten heart is one with the fire which lurks for our uses in the grey and homely flint, so the vital flame of beauty is one and the same, though kindled now to higher and now to humbler purpose, whether it be manifest in the creations of a Phidias, or of a Michel Angelo, of an Ictinus, or of some nameless builder of a sublime cathedral; in a jewel designed by Holbein or a lamp from Pompeii, a sword-hilt from Toledo, a caprice in ivory from Japan, or the enamelled frontlet of an Egyptian queen. We say, further, that the absence of this perception is fraught with infinite mischief, direct and indirect, to the development of art among us, tending, as it does, to divorce from it whole classes of industrial production, and incalculably narrowing the field of the influence of beauty in our lives. And with the absence of this true æsthetic instinct, we find not unnaturally the absence of any national consciousness that the sense of what is beautiful, and the manifestation of that sense through the language of art, adorn and exalt a people in the face of the world and before the tribunal of history; a national consciousness which should become a national conscience—a sense, that is, of public duty and of a collective responsibility in regard to this loveliest flower of civilisation. Well, it is in the belief that the consciousness of which I have spoken is rather dormant with us than absent, waiting to be aroused rather than wholly wanting, that the founders of this Association have initiated the movement which has brought you together and laid upon me the ungracious task to which I am now addressing myself—a task I have accepted in the hope that at least some good to others may come out of the wreck and ruin of any character for courtesy which may hitherto have been conceded to me.

But let us now look closer into my indictment; and let us first, for a moment and by way of getting at a standard, turn our thoughts to one or two of those races among which art has reached its highest level, and round whose memory art has shed an inextinguishable splendour. Let us first consider the Greek race in the day of its greatest achievements and the most perfect balance of its transcendent gifts. What is it that impresses us most in the contemplation of the artistic activity of this race? It is, first, that the stirring æsthetic instinct, the impulse towards and absolute need of beauty, were universal with it, and lay, a living force, at the root of its emotional being; and, secondly, that the Greeks were conscious of this impulse as of a just source of pride and a sign of their supremacy among the nations. So saturated were they with it that whatever left their hands bore its stamp. Whatever of Greek work has been preserved to us, temple or statue, vessel or implement, is marked with the same attributes of stately and rhythmic beauty; in all their creations from the highest to the lowest one spirit lives, and whatever be the rank of each of these creations in the hierarchy of works of art, in one thing they are evenborn and kin—in the spirit of loveliness. And of the dignity of this artistic instinct, which they regarded as their birthright, they were, as I have said, proudly conscious. Would you have an instance of this high consciousness? Here is one. At the end of the first year of the Peloponnesian war the Athenians having, according to ancestral custom, decreed a public funeral to those who had fallen in battle, Pericles, the son of Xanthippus, was chosen by them to speak the praises of the dead. It is a famous speech that in which he obeyed their injunction, and it opens with a lofty eulogy of the Republic for which the heroes whom they mourned had fallen. In this magnificent song of praise he enumerates the virtues of the Athenians; he shows them heroic, wise, just, tolerant, lovers of beauty, philosophers, in all things foremost among men. Mark this! At a celebration of the most moving solemnity—in a breathing space between two acts of a gigantic international struggle for hegemony—you have here a great statesman enumerating the titles of his fellow-citizens to headship among the nations, and placing not at the end of his panegyric and as an oratorical embellishment, but in its very heart and centre these words, "We love the beautiful."

But we may gain perhaps a yet more vivid sense of the extent to which the artistic impulse possessed and filled this people in the fascinating epitome of Grecian handicraft which is presented to us at Pompeii, or rather in the Museo Nazionale at Naples. Here you have the work not of Athenian Greeks of the Periclean or of the Alexandrian age, but the work of provincial Greeks inhabiting a watering-place of no very great importance, in the first century of our era; a period as far removed from the days of the Parthenon sculptures as we are from those of the "Canterbury Tales." And what a display it is! How full of interest! Here we are admitted into the most intimate privacy of a multitude of Pompeian homes—the kitchens, the pantries, the cellars of the contemporaries of the Plinies have here no secret for us, indeed, for aught we know, more than one of those dinners of which that delicate *bon-vivant*, the nephew of the naturalist, was so appreciative a judge, may have been cooked in one of these very ranges—one of those ladles may have skimmed his soup—his quails may

have been roasted on yonder spit. Nothing is wanting that goes to make the complete armament of a kitchen—stoves, caldrons, vessels of every kind, lamps of every shape, forks, spoons, ladles of every dimension. And in all this mass of manifold material perhaps the most marked characteristic is not the high level of executive merit it reveals, high as that level is, but the amazing wealth of idea, the marvellous intellectual activity brought to bear on what we now call objects of industrial art—whatever that may mean—in this outpost of Greek civilisation. These accumulated appliances of the kitchen and the pantry form a museum of art—a museum of art of inexhaustible fascination; and not only does this vast collection of necessary things contain nothing ugly, but it displays, as I have just said, an amazing wealth of ideas; each bowl, each lamp, each spoon almost, is an individual work of art, a separate and distinct conception, a special birth of the joy of creation in a genuine artist. But, above all, let us bear this main fact in mind—the absence there of any ugly thing; for the instinct of what is beautiful not only delights and seeks to express itself in lovely work, but forbids and banishes whatever is graceless and unsightly.

As next to the Greeks, and as almost their equals in this craving for the beautiful, the Italians will occur to you. And here it may be well to note, in a parenthesis, that a vivid sense of abstract beauty in line and form does not necessarily carry with it a keen perception of shapeliness in the human frame. This curious fact we see strikingly illustrated in a race which possesses the artistic instinct in certain of its developments in a greater degree than any other in our time—I mean the Japanese. With them the sense of decorative distribution and of subtle loveliness of form and colour is absolutely universal, and expresses itself in every most ordinary appliance of daily life, overflowing, indeed, into every toy or trifle that may amuse an idle moment; and yet majesty and beauty in the human form are as absent from their works as from their persons. Be this said without prejudice to the fact that in the movement imparted by them to the figures in their designs there is often much of daintiness and dignity, the outcome of that keen perception of beauty of line in the abstract which we have seen to be dominant in them.

I need not follow further this, I think, interesting train of thought, but the digression seemed to me useful, not as illustrating the fact that beauty is not to be regarded only in connection with the human form, which is a mere truism, but as showing that the abstract sense of it, in certain aspects, may possess and penetrate a race in which the perception of comeliness in the human body is almost entirely absent; and I meet by it also, in anticipation, certain objections that may suggest themselves to you in connection with the Italians, as far, at least, as the Tuscans are concerned; for in them, too, we find occasionally side by side with an unsurpassed sense of the expressiveness of line and form, a defective perception of beauty in the human frame—witness the ungainly angularities, for instance, of a Verocchio, a Gozzoli, a Signorelli. The thirst for the artistically delightful was the mark in Italy of no particular class; it was common to all, high and low, to the Pontiff on his throne, to the trader behind his counter, to the people in the market place. And here, again, observe that this desire was not alone for the adornment of walls and public places with painting and statuary—though every wall in every church or public building was, in fact, enriched by the hand of painters and of sculptors—but it embraced every humbler form of artistic expression, and was, indeed, specially directed to one which has in our time touched, here and there, a melancholy depth—the craft of the goldsmith. I said "humbler form" of art for lack of a better word, for a craft cannot fitly be called humble which has occupied and delighted men of the very highest gifts. Did not the mind that conceived the "Perseus" of the Loggia dei Lanzi pour out some of its richest fancies in a jewelled salt-cellar for the table of a Pope? Did not the sublimest genius that ever shone upon the world of art receive its first guidance in the workshop of a jeweller—a jeweller who was himself a painter also of high renown? For was it not that painter-goldsmith whose hands adorned with noble frescoes the famous choir of Sta Maria Novella?

Now, to a cultured audience such as that which I am here addressing, these facts are familiar and trite, so trite and so familiar that it may, perhaps, be doubted whether their true significance has ever stood quite clearly before your minds, and whether you have fully grasped the solidarity of the arts—if I may use an outlandish expression—which at one time prevailed. Let us in imagination transfer the last quoted fact into contemporary life. Let us suppose that the municipality of a great English city, proud of its annals and of its culture, determined to decorate with paintings in some comprehensive manner the walls of a great public building; and suppose, further, that an artist, admittedly of the first rank, were to answer to its call from the workshop—and I say advisedly from the workshop, for it is there, and not on an arm-chair in the office, that the head of the house would have been found in the old days—suppose, I say, that such an artist came forth from some great firm of

jewellers in Bond Street, for instance, we should have, on the artistic side, the exact parallel of the case of the Dominicans of Sta Maria Nuova and Domenico, the son of Thomas the garland-maker of Florence. Meanwhile, striking as is this instance of the unity of art in long past days, it is but just to add—and I rejoice to be able here to do so—that signs are not wanting on the side of our own artists of a strong tendency towards a return to closer bonds between its various branches, in which direction, indeed, a movement has been for some years increasingly marked and practical; and it is with a glad outlook into the future, and with a sense of breathing a wider air, that I place by the side of the cases which I have just mentioned—cases which were in their time of natural and frequent occurrence—one which is of yesterday:—The chief magistrate of an important provincial centre of English industry, the Mayor of Preston, wears at this time a chain of office which is a beautiful work of art, and this chain was not only designed but wrought throughout by the sculptor who modelled the stately commemorative statue of the Queen that adorns the County Square of Winchester, the artist who presides over the section of sculpture in this congress, my young friend and colleague, Mr. Alfred Gilbert.

I have pointed to the Italians and the Greeks as culminating instances of peoples filled with a love of beauty and achieving the highest excellence in its embodiment, and I have named the Japanese as manifesting the æsthetic temper in high degree of sensitiveness, but within certain limitations. It is not necessary to remind you that I might extend this list, if with some qualification, and that the same lesson—the lesson that the nations which love beauty seek it in the humblest as well as in the highest things—is taught us by others than those I have mentioned. Whosoever, for instance, has wondered at the work of Persian looms, or felt the fascination of the manuscripts illuminated by the artists of Iran, or noted the unflinching grace of subtle line revealed in their metalwork, will feel that for this race also the merit of a work of art did not reside in its category, but in the degree to which it manifested the spirit which alone could ennoble it—the spirit of beauty. And if, further, this dominant instinct of the beautiful is not in our own time found in any Western race in its fullest force, and among one Eastern people with, as we saw, important limitations, there is yet one modern nation in our own hemisphere in which the thirst for artistic excellence is widespread to a degree unknown elsewhere in Europe; a people with whom the sense of the dignity of artistic achievement, as an element of national greatness, an element which it is the duty of its Government to foster and to further and to proclaim before the world, is keen and constant—I mean, of course, your brilliant neighbours, the people of France. Here, then, are standards to which we may appeal to see how far, all allowance being made for many signs of improvement in things concerning art, we yet fall short, as a nation, of the ideal which we should have before us.

Let me now revert to my indictment. I said that the sense of abstract beauty with the mass of our countrymen—and once again I must be understood not to ignore, but only to leave out of view for the moment, the considerable and growing number of those in whom this sense is astir and active—with the mass, I repeat, of our countrymen, the perception of beauty is blunt, and the desire for it sluggish and superficial; with them the beautiful is, indeed, sometimes a source of vague, half-conscious satisfaction, especially when it appeals to them conjointly with other incitements to emotion, but their perception of it is passive, and does not pass into active desire; it accepts, it does not demand; it is uncertain of itself, for it lacks definiteness of intuition, and, having no definite intuition, it is necessarily uncritical. This weakness, among the many, of the critical faculty in æsthetic matters, and the curious bluntness of their perceptions, is seen not in connection with the plastic arts only, but over the whole artistic field—in the domains of music and the drama, as in that of painting and sculpture. Who, for instance, where a body of English men and women has been gathered together in a concert-room, has not, at one moment, heard a storm of applause go up to greet some matchless executant of noble music, and then, five minutes later, watched in wonder and dismay the same crepitation of eager hands proclaiming an equal satisfaction with the efforts of some feeblest servant of Apollo? Or have you not often, in your theatres, blushed to see the lowest buffoonery received with exuberant delight by an audience—and a cultivated audience—which had just before not seemed insensible to some fine piece of histrionic art? And what could proclaim the lack of true, spontaneous instinct in more startling fashion than the notorious fact that the most thrilling touch of pathos in the performance of an actor reputed to be comic will be infallibly received with a titter by a British audience, which has paid to laugh and come to the play focussed for the funny? Now this little glimpse into the attitude of the public in regard to other arts than ours has its bearing upon our present subject. This same feebleness of the critical sense which arises out of the indefiniteness—to say the best of it—of the inner standard of artistic excellence, is not unnaturally accom-

panied by and fosters an apathy in regard to that excellence, and an attitude of callous acquiescence in the unsightly, which are inexpressibly mischievous; for you cannot too strongly print this on your minds, that what you demand that you will get, and according to what you accept will be that which is provided for you. Let an atmosphere be generated among you in which the appetite for what is beautiful and noble is whetted and becomes imperative, in which whatever is ugly and vulgar shall be repugnant and hateful to the beholder, and assuredly what is beautiful and noble will in due time be furnished to you, and in steadily increasing excellence, satisfying your taste, and at the same time further purifying it and heightening its sensitiveness. The enemy, then, is this indifference in the presence of the ugly; it is only by the victory over this apathy that you can rise to better things; it is only by the rooting out and extermination of what is ugly that you can bring about conditions in which beauty shall be a power among you. Now, this callous tolerance of the unsightly, although it is, I am grateful to think, yielding by degrees to a healthier feeling, is still strangely prevalent and wide-spread among us, and its deadening influence is seen in the too frequent absence of any articulate protest of public opinion against the disfigurement of our towns.

Let me give you an instance of this indifference. Our country is happy in possessing a collection of paintings by the Old Masters of exceptional interest and splendour, a collection which, thanks to the taste and highly-trained discernment of its present accomplished head—Sir Frederick Burton—is, with what speed the short-sighted policy of successive Governments permits, rising steadily to a foremost place among the famous galleries of the world. Some years ago the building destined to receive it being found no longer adequate, it became necessary to provide by some means ampler space for the display of the national treasure. It was resolved that another edifice should take the place of that designed by Wilkins, an edifice which, be it said in passing, had been made the butt of curiously unmerited ridicule in the world of connoisseurship, and which, apart from certain very obvious blemishes, it has always seemed to me to be much easier to deride than to better. A competition was opened, and designs were demanded for a spacious building, equal to present and future needs, and worthy of the magnificence of the collection it was to house. It is hardly necessary to say that we have here no concern whatever with the controversy which arose over these designs. My concern is with its final outcome, which is this: the original building has remained unaltered as to its exterior; but, on the rear of one of its flanks loom now into view, first an appendage in an entirely different style of architecture, and further on, an excrescence of no style of architecture at all, the one an Ital tower, the other a flat cone of glass, surmounted by a ventilator—a structure of the warehouse type—the whole resulting in a jarring jumble and an aspect of chaotic incongruity which would be ludicrous if it were not distressing; and we enjoy, further, this instructive phenomenon—that a public opinion which sensitively shrank from the blemishes of the original edifice has accepted its retention, with all those blemishes unmodified, *plus* an appendage which adds to the whole the worst, almost, of all sins architectural—a lack of unity of conception. Now, I have never to my knowledge heard one single word of articulate public reprobation levelled at this now irremediable blot on what we so complacently call the finest site in the world; and yet I cannot find it in me to believe that many have not, like myself, groaned in spirit before a spectacle so deplorable—a spectacle which, indeed, is only conceivable within these islands. I think that a good deal is summed up in this episode, and I need not, for my present purpose, seek another in the domain of architecture.

In regard to sculpture, the public apathy and blindness are yet more depressing and complete, and illustrate the deadness of the many to the perception of the essential qualities of art. To the overwhelming majority of Englishmen sculpture means, simply, the perpetuation of the form of Mr. So-and-So in marble, bronze, or terra-cotta—this, and no more. That marble, bronze, or terra-cotta may, under cunning hands, become vehicles for those who have eyes to see, of emotions, æsthetic and poetic, not less lofty than those which are stirred in us by the verse of a Dante or a Milton, or by the strains of noblest music—of this, the consciousness is for practical purposes non-existent. For sculpture, for an art through which, alone, the name of Greece would have been famous for all time, there is, outside portraiture, even now, under conditions admittedly improved, little or no field in our country. Portrait-statues, galore, bristle, indeed, within our streets; but the notion of setting up in public places pieces of monumental sculpture solely for adornment and dignity, or of monuments that shall remind us of deeds in which our country or our town has earned fame and deserved gratitude, and incite the young to emulation of those deeds, or that shall be the allegorised expression of any great idea—and yet our race has had great ideas, and clothed them in deeds as great—hardly ever, it would seem, enters the heads of a people whose aspirations are surely not less noble or less high than those of other nations. Nay, even a monument

commemorative of the great public services of some individual man which shall be a monument to him rather than exclusively an image of him, a monument of which his effigy shall form a part, but of which the main feature shall be the embodiment or illustration, in forms of art, of the virtues that have earned for him the homage of his countrymen—even this is suggested in vain. And if we are tolerant of treason against fitness in architecture, what shall we say of our tolerance in regard to its sculptural adornments? What shall we say of the complaisant acceptance, above and about windows and doorways in clubs, offices, barracks, and the like buildings, of carven wonders such as no civilised community would accept in silence? Though I fear I must here, with all deference, add that my brethren, the architects, who suffer their work to be so defaced, are themselves not wholly blameless; and, indeed, it is a truth, in the assertion of which the most enlightened workmen in every branch of art will stand by me, that among ourselves also the sense of the kinship of the arts is too often a mere theory, received, no doubt, with respect as an abstract proposition, but not perceptibly colouring our practical activity. In sculpture the inertness of the demand and tolerance of inferior supply is due mainly to the want, to which I have alluded, of a sense of and a joy in the purely æsthetic quality in artistic production, an insensibility to the power inherent in form by its own virtue, of producing emotion and exciting the imagination—a power on which the dignity of this pure and severe art does or should mainly rest.

In the appreciation of painting, which, on various grounds appeals as an art to a far wider public than either architecture or sculpture, the same shortcomings are evident, though in a less degree and with less mischievous results; for the witchery of colour, at least, is felt and appreciated, more or less consciously, by a very large number of people. The inadequacy of the general standard of artistic insight is here seen in the fact that, to a great multitude of persons, the attractiveness of a painted canvas is in proportion to the amount of literary element which it carries, not in proportion to the degree of æsthetic emotion stirred by it, or of appeal to the imagination contained in it—persons, those, who regard a picture as a compound of anecdote and mechanism, and with whom looking at it would seem to mean only another form of reading. Time after time, in listening to the description, the enthusiastic description, of a picture, we become aware that the points emphasised by the speaker are such as did not specially call for treatment in art at all, were often not fitted for expression through form or colour, their natural vehicle being not paint but ink, which is the proper and appointed conveyer of abstract thoughts and concrete narrative. I have heard pictures extolled as works of genius simply because they expressed, not because they nobly clothed in forms of art, ideas not beyond the reach of the average penny-a-liner. Now I know that in what I am here saying I skirt the burning ground of controversy long and hotly waged—skirt it only, for that controversy touches but the borders of my subject, and I shall of course not pursue it here. I will, nevertheless, to avoid misrepresentation in either sense, state, as briefly as I can, one or two definite principles on which it appears to me safe to stand.

It is given to form and to colour to elicit in men powerful and exquisite emotions, emotions covering a very wide range of sensibility, and to which they alone have the key. The chords within us which vibrate to these emotions are the instrument on which art plays; and a work of art deserves that name, as I have said, in proportion as, and in the extent to which, it sets those chords in motion. The power and solemnity of a simple appeal of form as such is seen in a noble building of imposing mass and stately outlines. When, however, form in art is connected with the human frame, and when combinations of human forms are among the materials with which a beautiful design is built up, then another element is added to the sum of our sensations—an element due to the absorbing interest of man in all that belongs to his kind; and the emotion primarily produced by the force of a purely æsthetic appeal is enhanced and heightened by elements of a more intimate and universal order, one more nearly touching our affections, but not, therefore, necessarily of a higher order. Thus the episode, for instance, of Paolo and Francesca, clothed in the rare, grave melody of Dante's verse, entrances us with its pathos; but our emotion, intensely human as it is, is not therefore of a higher kind than that which holds us as we listen to sounds sublimely woven by some great musician; nor are the impressions received in watching from the floor of a great Christian church the gathering of the gloom within a great dome's receding curves of less noble order than those aroused by a supreme work of sculpture or of painting—by, say, the *Notte* of Michel Angelo or the *Mona Lisa* of Leonardo; and yet in both of these last the chord of human sympathy is strongly swept, though in different ways—in the *Notte* by the poetic and pathetic suggestiveness of certain forms and movements of the human body; in the *Mona Lisa* by a more definitely personal charm and feminine sorcery

which haunts about her shadowy eyes, and the subtle curling of her mysterious lips. I say, then, that in a work of art the elements of emotion based on human sympathies are not of a loftier order than those arising out of abstract sublimity or loveliness of form, but that the presence of these elements in such a work, while not raising it as an artistic creation, does impart to it an added power of appeal, and that, therefore, a work in which these elements are combined will be with the great majority of mankind a more potent engine of delight than one which should rest exclusively on abstract qualities. And it follows, therefore, that while a work of art earns its title to that name on condition only, once again I say, of the purely æsthetic element being present in it, and will rank as such in exact proportion to the degree in which this element prevails in it; and while, further, this element, carrying with it, as it does, imaginative suggestiveness of the highest order and of the widest scope, is all sufficient in those branches of art in which the human form plays no part, the element which is inseparable in a work of art from the introduction of human beings is one which it is not possible for us to ignore in our appreciation of that work as a source and vehicle of emotion.

Every attempt at succinct exposition of a complex question risks being unsatisfactory and obscure, and I am painfully alive to the inadequacy of what I have just said. I trust, however, that I have conveyed my meaning, if roughly, yet sufficiently to shield me from misconception in regard to the special emphasis I am laying on the importance of a proper estimation of the essentially æsthetic quality in a work of art, an importance which I urge upon you not so much here on account of the effect its absence may have exercised on the development of painting, as on account of the significant fact that its want—the lack of a perception that certain qualities are the very essence of art, and link into one great family every work of the hands of men in which they are found—has led with us to a disastrous divorce between what is considered as art proper and the arts which are called industrial. I say advisedly “disastrous,” for the lowering among us in the present day of the status of forms of art in the service of which such men as Albert Dürer, for example, and Holbein (men, by-the-by, of kindred blood with ourselves), Cellini, and Leonardo, were glad to labour and create—and that not as a concession but in the joyful exercise of their fullest powers—is one of its results, and, carrying with it, as is natural, a lowering of standard in these arts, has generated the marvellous notion, not expressed in words, but too largely acted on, that art in any serious sense is not to be looked for at all in certain places—where, in truth, alas! neither is it often found—and led to the holding aloof to a great extent, until comparatively recent years, of much of the best talent from very delightful forms of artistic creation; and this notion has led further to the virtual banishment from certain provinces of designing of the human figure, or, where it is not banished, to its defacement, too often, in the hands of the untrained or the inept. We are to a wonderful degree creatures of habit, our thoughts are prone to run—or shall I not rather say, to stagnate?—within grooves; and, if we are a people of many and of great endowments, a swift and free play of thought is, as we have been forcibly told by a voice that we shall hear no more—and can ill miss—not a distinguishing feature among us. Is it not an amazing thing, for example, that human shapes, which in clay or plaster would be ignominiously excluded from a second-rate exhibition, are not only accepted, but displayed with a chuckle of elated pride when cast in the precious metals, flanked, say, by a palm tree, borne aloft on a rock, and presented in the guise of a piece of ornamental plate? But is this even rare? Is it not of constant occurrence? Do you demur? Well, let me ask you a plain question—Of all the nymphs and goddesses, the satyrs and the tritons, that disport themselves on the ceremonial goldsmithery of the United Kingdom, how many if cast in vulgar plaster and not in glittering gold would pass muster before the jury of an average exhibition? And if few, I ask why is this so? In the name of Cellini—nay, in the name of common sense—why? And is it on account of the low ebb of figure modelling for decorative purposes that on our carved furniture—what we mysteriously describe as “art furniture”—the human form is hardly ever seen? Then why is the best talent not enlisted in this work? Certain it is that the absence of living forms imparts to much of the furniture now made in England, unsurpassed as it is in regard to delicacy and finish of handiwork, and frequently elegant in design, a certain look of slowness and flimsy, faddy dilettantism which prevents it from taking that rank in the province of applied art to which it might and should aspire.

But I have, I fear, already unduly drawn upon your patience, and I must bring to a close these too disjointed prefatory words, leaving it to the accomplished gentlemen who head the various sections of this congress to amplify and enrich as they will, out of the wide fund of their knowledge and experience, the bald outline I have sketched before you. They, in their turn, taking up, no doubt, our common parable, will emphasise and press on you the fact that by cultivating its

æsthetic sense in a more comprehensive and harmoniously consistent spirit than hitherto, and with a clearer vision of the nature of all art, and a more catholic receptiveness as to its charms, and by stimulating in a right direction the abundant productive energy which lies to its hand, this nation will not only be adding infinitely to the adornment and dignity of its public and private life, not only providing for itself an increasing and manifold source of delight and renovating repose, mental and spiritual, in a day in which such resting and regenerating elements are more and more called for by our jaded nervous systems, and more and more needed for our intellectual equilibrium, but will be dealing with a subject which is every day becoming more important in relation to certain sides of the waning material prosperity of the country. For, as they will no doubt remind you, the industrial competition between this and other countries—a competition keen and eager, which means to certain industries almost a race for life—runs, in many cases, no longer exclusively or mainly on the lines of excellence of material and solidity of workmanship, but greatly nowadays on the lines of artistic charm and beauty of design. This, to you, vital fact is one which they will, I am convinced, not suffer to fall into the background.

One last word in anticipation of certain objections not unlikely to be raised against an assumption which may seem to be implied in the existence of our Association—the assumption that the evils and shortcomings of which I have spoken with such unsparing frankness can be removed or remedied by the gathering together of a number of persons to listen to a series of addresses. The causes of these evils, we may be told, and their antidote, are not on the surface of things, but rest on conditions of a complex character, and are fundamental. "Who," I hear some one say, "is this dreamer of dreams, who hopes to cure by talking such deep-seated evils? Who is this shallow and unphilosophical thinker who does not see that the same primary conditions are operative in making the purchaser indifferent to what he gets and the supplier indifferent to what he produces, and who attributes the circumstance that good work is not generally produced in certain forms of industry to the lack of demand, rather than to the deeper-lying fact that suppliers and demanders are of the same stock, having the same congenital failings, and satisfied with the same standards?" My answer to this imaginary, or I ought, perhaps, to say this foreseen, objector would be, firstly, this—that I am not the visionary for whom he takes me, and that I do not believe in the efficacy of words either directly to remedy the state of things I have been deploring, or to create a love of art and a delicate sensitiveness to its charms in those to whom the responsive chords have been refused; neither is the eloquence, trumpet-toned and triumphant, conceivable by me before which the walls of the Jericho of the Philistine shall crumble in abrupt ruin to the ground; least of all do I believe in sudden developments of the human intellect. But it has nevertheless seemed to me, as it has seemed to the framers of this Association, that words, if they be judicious and sincere, may rally and strengthen and prompt to action instincts and impulses which only await a signal to assert themselves—instincts sometimes perhaps not fully conscious of themselves—and that a favouring temperature may be thus created within which, by the operation of natural laws, in due time, but by no stroke of the wand, a new and better order may arise. Neither, indeed, do I ignore the force of my critic's contention that the causes of mischief lie deep, and are not to be touched by surface-tinkering, if they are to be removed at all; though I demur to his pessimistic estimate of them as a final bar to our hopes.

It is true that certain specific artistic attributes are, or seem to be, feeble in our race; it is true, too true—I have it on the repeated assurance of apologetic vendors—that with us the ugliest objects—often, oh, how ugly!—have the largest market; nevertheless, the amount of good artistic production in connection with industry—I purposely speak of this first—has grown within the last score or so of years, and through the initiative, mind, of a mere handful of enthusiastic and highly gifted men, in an extraordinary degree; and in a proportionate degree has the number increased also of those who accept and desire it; and this growth has been steady and organic, and is of the best augury. Now, the increase in the number of those who desire good work, and the concurrent development of their critical sensitiveness in matters of taste, stimulate, in their turn, the energies and sustain the upward efforts of the producers, and thus, through action and reaction, a condition of things should be slowly but surely evolved which shall more nearly approach that general level of artistic culture and artistic production so anxiously looked for by us all. It is in the hastening of this desired result that we invoke, not your sympathy alone, but your patient, strenuous aid. And if I am further asked how, in my view, this Association can best contribute to the furtherance of our common end, I would say, not merely by seeking to fan and kindle a more general interest in the things of art, but mainly by seeking to awaken a clearer perception of the true essence of a work of art, by insisting on the funda-

mental identity of all manifestations of the artistic creative impulse, through whatever channels it may express itself, and by setting forth and establishing this pregnant truth—that whatever degrees of dignity and rank may exist in the scale of artistic productions, according to the order of emotion to which they minister in us, they are one in kind; for the various and many channels through which beauty is made manifest to us in art are but the numerous several stops of one and the same divine instrument. And if in what I have said I have laid especial stress on that branch of art which is called industrial, it is not solely to develop this cardinal doctrine, neither only because of the pressing, practical, paramount, national importance of this part of our subject, but also because I, in truth, believe that it is in a great measure through these very forms of art that the improvement, to which I look with a steadfast faith, will be mainly operated. The almost unlimited area which they cover in itself constitutes them an engine of immense power, and I believe that through them, if at all, the sense of beauty and the love for it will be stimulated in, and communicated to, constantly increasing numbers. I believe that the day may come when public opinion, thus slowly but definitely moulded, will make itself loudly heard; when men will insist that what they do for the gracing and adornment of their homes shall be done also for the public buildings and thoroughfares of their cities; when they will remind their municipal representatives and the controllers of their guilds of what similar bodies of men did for the cities of Italy in the days of their proud prosperity in trade, and will ask why the walls of our public edifices are blank and silent, instead of being adorned and made delightful with things beautiful to see, or eloquent of whatever great deeds or good work enrich and honour the annals of the places of our birth. And, lastly, I believe that an art desired by the whole people and fostered by the whole people's desire would reflect—for such art must be sincere—some of the best qualities of our race; its love of nature, its imaginative force, its healthfulness, its strong simplicity.

And now, ladies and gentlemen, my task is ended. My duties to-night were purely prefatory; my words are but the prologue to the proceedings which begin to-morrow—a prologue which I undertook to speak less from any faith in its possible efficacy than in the belief that the first word spoken at such a time should be heard from the lips of one to whom, from the nature of the office he is privileged to fill as well as from the whole bent of his mind, everything that concerns art, from end to end of its enchanting field, must be, and is, a source of deep, of constant, and engrossing interest. The curtain is now raised, the stage is spread before you, and I step aside to make way for others, leaving with you the expression of my fervent wish that the hopes which have brought us together in this place may not have been entertained in vain.

[HAMO THORNYCROFT, R.A.]

ON THE GRETA, YORKSHIRE.

BORASTON CHAPEL.

THIS is one of the two ancient chapels of the parish of Boraston, part of the manor of Burford, on the southern extremity of Shropshire. A chancel and vestry have been added, a substantial bell-tower and porch built, and the interior refitted to seat 143 persons.

The old walls are Norman, and batter considerably inside and slightly on the exterior. There remain traces of two doorways of that period, but the mouldings and face of the ancient masonry have long ago been hacked off and the surface stuccoed. The walls were raised, or rebuilt at top, with ashlar walling in the fourteenth century, and there are two windows of this date. These, the only ancient features remaining, have been restored, some of the stones being undisturbed. The external stucco was very readily removed, exposing the pleasant warm colour of the ancient red sandstone ashlar. The belfry, spire, and porch are entirely of local oak, given by the late Lord NORTHWICK. The spire is covered with cleft oak shingles. The pulpit, screen, and chancel fittings are also of oak, and handsome in character. Some of them were made by Mr. JAMES FORSYTH, of Hampstead, from the architect's designs. We give an illustration of the pulpit. The architect was Mr. CURZON, of Lincoln's Inn Fields, and the builder Mr. W. HOWELLS a parishioner.

## NOTES AND COMMENTS.

THE report of the meeting of ROBERT BOYLE & SON, Limited, which we published last week, is gratifying for several reasons. When a company that is so closely associated with building can declare a dividend of 12 per cent., it is evident that the building trade in general is reviving, for it may be assumed that a large share of the profit was derived from the ventilation of public and private buildings recently constructed. We may also conclude that the demand for ventilators is increasing. That is partly owing to a more general recognition of the fact that air should be removed constantly if a room is to be kept in a habitable condition, but we must also say that the very low price at which the air-pump ventilator is available has no small influence upon the ideas of the public about sanitation. It is no longer necessary to have an apparatus which, however doubtful may be its efficiency, is cumbersome, costly, and promises to be a cause of expense. The air-pump ventilators made their way because they were simple in principle and were without any cause of weakness which would interrupt the uniformity of their action. Improvements were effected from time to time both in the form of the ventilators and in the processes for their production. By means of those which are protected under the patent of 1882, Mr. ROBERT BOYLE was able to announce at the meeting that the cost of the air-pump ventilators is now 50 per cent. under former prices, with the advantage of increased efficiency. As steel has superseded wrought-iron in other fields, it now is used for the ventilators, and the lightness and toughness of the material may be expected to produce more grace in the form of the ventilator. The business of the company is increasing not only in England but abroad. Every one who is aware of the severe tests which are imposed on appliances before they are used in the public buildings of the Continent will recognise the foreign successes of the ventilator as one of the best guarantees of its effectiveness as an air-changer.

THE skill of Mr. RICHARD BEAVIS in painting animals was recognised long ago, but few would credit him with being also a landscapist and a colourist. The pictures and studies of Spanish subjects in Messrs. TOOTH's gallery will be a surprise to many amateurs. They form a delightful exhibition, for in looking at them one feels the competence of the artist to put on canvas any scene or figure which gives him pleasure. There is no straining after novel effects. Mr. BEAVIS frankly renders what he saw on bright days, and the smallest sketch will seem to convey some sunshine to a room on a dark day. The marine paintings are as successful as those of mountains, except one where a three-master sails perilously near the shore. As was to be expected, there are pictures of Spanish horses, bullocks, mules, sheep, and goats, and, of course, scenes from a bull-fight. Mr. BEAVIS was lucky in having a day when horses were used for the *corridas* which were worth drawing, and when the *alguacil* did not seem to be an undertaker's assistant. His *Collecting the Fighting Bulls* is one of his best pictures. Among the landscapes we may mention *Tilting o'er the Wave, Where Guadalquivir's waters glide, Barcelonetta, Mont Sevos, Bridge over Ebro, and the Torre des Infantas*. In the last the delicate pink of the Alhambra brickwork is caught. But every one of the fifty-five pictures will sustain a scrutiny.

M. PAUL FOUCART, the Director of the French School at Athens, has reported to the Académie des Inscriptions that excavations on the site of the Temple of the Muses at Thespeia, have been commenced. He has placed M. JAMOT in charge of the work. In the course of eleven days the substructure of the temple has been exposed, and among the discoveries are Ionic capitals, fragments of bronze, several inscriptions, some of them relating to the dedication of the statues erected by the Thespeians in honour of SYLLA, AGRIPPA, &c. The works are to be continued whenever the weather is favourable. Thespeia was said to possess a theatre and agora which were worthy of inspection, and statues of *Venus, Cupid, and Phryne*, by PRAXITELES. PAUSANIAS also mentions two temples, a naos, and twenty-two statues. In the beginning of the present century the ground was visited by DODWELL, and he remarked that valuable antiquities and inscriptions might

be found there with a little trouble and expense. The French archæologists have apparently done well when they decided on an exploration of Thespeia.

At the meeting of the Manchester Architectural Association on Tuesday there was a discussion upon "The Improvement of the City," after the manner of one which took place lately in a Manchester Club. The following resolution was afterwards adopted:—"That this Association respectfully recommend to the corporation the formation of a committee composed mainly of gentlemen outside the corporation whose duty shall be to advise on all artistic questions connected with street improvements." The proposal is a good one, but after the Metropolitan Board's experience of what the Royal Institute of British Architects contrived to do with Northumberland Avenue, the Manchester Corporation may be pardoned if they hesitate about the adoption of the resolution.

AN international competition is opened for designs for a Musée in Gothenburg, Sweden. The treasures which are to be housed consist of works of art, coins and medals, natural history, books, ethnographic and archæological objects. It is left to the competitors to decide whether there is to be a single building for all the collections, or separate buildings. In the latter case it is prescribed that the works of art, specimens to illustrate natural history, and the library should occupy the principal parts of the buildings, and that provision should be made for ulterior enlargements. Fireproof materials are to be used, with stone for the façades. The sum to be laid out, including ventilation, lighting, heating, water supply, architects' fees, &c., is put down at 1,200,000 kronen, or about 66,700*l.* The designs are to be sent in to the directors before January 1. The first prize will be about 133*l.*

THE painters of Vienna are not forgetful of the fate of MARIE ANTOINETTE under the Revolution, which the International Exhibition next year is to celebrate. They have held a meeting at which it was decided that they will not be contributors to the galleries. This resolution is to be regretted, for by it M. MUNKACSV's pictures will be excluded, and there are several other artists whose works would be among the attractions of the Exhibition.

EVERYONE who was acquainted with CHARLES HANSOM, of Bristol, will regret the loss of one who was not only an able architect but a generous and most honourable man. He died at his house in Clifton on Friday last. Until recently Mr. HANSOM always seemed to be in the best of health, but in the beginning of the year cancer appeared, and eventually he succumbed to it. For nearly half a century he was a prominent man among the Roman Catholics, and erected many churches, convents, and schools for them throughout the country. He was one of the pioneers in the revival of Gothic and throughout his life he gave preference to the Decorated period. As far back as 1842 he erected a church in Coventry, and it was followed by others at Erdington, Edgehill, St. Ann's, Wolverhampton, York, Cardiff, Selby, Rugeley, Thurnham, Kenmare, Boulogne, Cheltenham, Bath, Clifton, &c. His Dominican Priory at Woodchester is one of his most admired works. The convents at Clifton, Stowe, Stoke, Loughborough, Taunton, Woodchester were erected from his designs, as well as Ratcliffe College, the central block of Downside College, the library at Ushaw. Among his recent works were the Clifton and Malvern Colleges, and Kelly College, Tavistock. He also was architect for the present church of St. Paul, Clifton, and the church at Barton Hill. Mr. HANSOM was full of energy, and naturally was enthusiastic about the Volunteer movement. He held a captain's commission in the local artillery corps, and a book of his on "Company Drill" was at one time recognised as an authoritative manual. With his fine physique and love of exercise, CHARLES HANSOM would be considered as likely to live to a patriarchal age, and, as long as he practised, he would be an honour to the profession. Mr. HANSOM was buried on Monday, and, at the desire of the local clergy, near one of his mortuary chapels in the Bath Cemetery.

## ARCHITECTURE AT THE ART CONGRESS.

IN the section of Architecture Professor Aitchison presided. In the opening address he observed it was said that it was not perhaps extraordinary that so little attention had been paid to the fine arts in England until lately, because the discovery of some of nature's laws and the application of those laws to machinery had created a state of things that never existed before. There were only two sections of mankind that were content to exist without architecture—the lowest savages and those who were in most respects the most highly civilised. The former were contented with the caves or lairs of wild beasts, while the latter only asked for buildings that met their more complex physical wants, but destitute of everything that appealed to their higher nature. The object of his address was to try and lift the civilised man from that state. Pure architecture, like music, might enthrall or entrance, but like music it was vague. Architecture and music were obtrusive arts. In one respect architecture had the advantage, for they might admire it in a desert, but without man or animals music almost ceased to exist. The fairer half of the population were taught the principles and practice of music from their early years; but who studied architecture, who knew the notes, who had learned counterpoint that he might be able to follow the intricacies of harmony through a building? And yet he presumed there were natures as capable of being enchanted by it as by music if the same training were bestowed. He asserted that the present parsimonious way of treating architects rendered it impossible to get the most highly finished they could design and workmen execute, and he said it was perfectly true that among the mass of the people there was no taste for architecture. Architecture supplied that grace to our habitations and that dignity to our public buildings that should be as necessary to our life as the air we breathe; the inside of our houses should be so graceful in form and so beautiful in colour as to restore to us the requisite calmness of mind that strife with the world or close application had robbed us of. And that the outside should be shapely and rhythmical was a debt due to the public. As a nation they sank in the scale of civilisation if they had nothing to show in their towns and capital but utilitarian ugliness, and they would have nothing to show of their former greatness, nor of the extent of their dominion, if they left behind them no buildings worthy of admiration and study. The Professor then spoke of the necessity and importance of building with that excess of strength and with that permanence that would resist the ravages of time. They would realise the importance of architecture if they considered the blank that would be left in sculpture and painting by expunging the architecture, and in literature by omission of all reference to it. Architecture, therefore, claimed more study and more appreciation. The rich and well-to-do might well reflect that it was not a perishable art, and that a magnificent mansion or public building might keep alive their name for centuries, when it would otherwise pass away with the generation in which they lived. There was often both a pecuniary and social advantage in magnificent architecture and decoration. But he rather insisted upon the public advantage as well as on the personal pleasure to be gained by the study and appreciation of noble architecture, even by those who could not afford to build, for their knowledge and appreciation would encourage a higher and deeper professional study, and would reward its success.

Sir James Picton said he hoped the congress would have a tendency to bring about that progress which was certainly needed in Liverpool in regard to the fine arts.

## Safety in Theatres.

Mr. E. J. Tarver read a paper on "Proposed Improvements in Theatre Planning," in order to show that fatal accidents occurred in theatres chiefly because people, when rushing out, were pent up between the enclosing walls of passages and staircases, and therefore the Legislature might enact a regulation that such passages and staircases should not be one inch longer than was necessary for traversing the distance between any seat in the house and the street doors. Mr. Tarver illustrated by means of a series of practical diagrams a means of shortening this distance to a minimum without sacrificing any of the requirements and comforts of the audience. He claimed that the number of seats, and consequently the profits of the management, were much increased by his plan, which had stood the test of criticism, and had met with the approval of those who were practically and professionally acquainted with the subject.

## Colour Theories and Experience.

Mr. G. H. Morton, jun., read a paper on "The Agreement of Colour Theories with Practical Experience." He expressed his opinion that a large number of British workmen and women might gain a livelihood from occupations in art works now done abroad were they but better educated in the matter of colour and design. This was mainly due to their neglect in

not studying the subject, and so learning to discriminate between the harmonious and the inharmonious and the pleasing and the unpleasant. A knowledge of the scientific rules of colour seemed to be much more needed in decorative than in picture-painting. Mr. Morton then gave a technical exposition of the combinations and effects of primary and secondary colours and pigments.

## Colour Decoration.

Mr. J. D. Crace read a paper on "The Proper Aims and Limits of the Coloured Decoration of Architecture." He said that although both architecture and decoration had in modern times been to some extent the playthings of fashion, the serious study of harmonious colouring had kept pace with the new development of architecture, and the art which had so nearly died out early in this century had started into fresh life. There were, however, numbers of able designers and ornamentists, although there were very few men who could so grasp the colour treatment of a large building as to add to its dignity and repose. There was, Mr. Crace remarked, an unfortunate tendency to undervalue the teaching of the historic past in art. This was partly due to the fact that so few leading artists had any knowledge of "architecture" or "applied art," and another cause was to be found in the charm of the Japanese art, although it should be remembered that that was the art of a people who had no architecture. The gravest impediment to "decorative art" was the existing separation between it and so-called "high art"—a separation quite as injurious to the latter as to the former.

## PAINTING AT THE ART CONGRESS.

MR. ALMA TADEMA, R.A., in his inaugural address to the members, said that it was with great pride that he had come to Liverpool to preside at the Painting Section of the National Art Congress, which the distinguished President of the English Royal Academy of Arts had opened with such a characteristically admirable address. Pictures were his usual means of communication with the public, and as he had somewhat neglected that study of the word which insured clearness of expression, he could not hope to convey as much to his audience as he trusted he had sometimes succeeded in doing through his pictures. The artist's highest aim and necessity were to convey to his fellow-creatures the impressions of beauty which he was constantly receiving, and which dominated his life. Those impressions varied with the individual. Some were sensitive to colour, others to forms, others to sound; and, according to the nature of his susceptibility, a man became a painter, a sculptor, an architect, or a musician. Still those different artists all belonged to one class of human beings—those whose calling it was to point to the beautiful, the elevated, the refined, and by so doing to heighten the existence of mankind. What sorrows, what sufferings were not alleviated by the charms of art? Who could listen to music in a beautiful cathedral without being uplifted? Who could stand unmoved before a masterpiece? If such a one was to be found, surely he must belong to the lowest of intellectual grades. These high sentiments were indefinable; it stood to reason, moreover, that they were felt in different degrees, since no two individuals were similarly affected, even by a common cause. It must be understood, however, that there was a standard by which art could be measured—the sanction of time and of nations. Thus they could not doubt the pre-eminence of Phidias, greatest among the great in the loftiest period of art—the time when Pericles ruled Athens, and Athens was the undisturbed head of Greece. Form had then attained its highest development. As for colour, its principal use was then to decorate architecture and sculpture, for the Greeks, they were told, painted their temples and statues, the latter probably in order to give them a more life-like appearance. We who were used to treat sculpture as an art complete in itself, and who had never seen any first-class statuary assisted by colour, found it difficult to imagine that this combination, of which the ancients were so fond, could have been satisfactory. Under the Romans art became still more realistic in form, more individually natural, and consequently more picturesque; a sense of colour was developed, which appealed more strongly to our sympathies. Mr. Tadema went on to say that play was essential to colour, and that play in form, if it did not actually destroy, at least did not add to its beauty. He continued:—Still the sacrificing of form to colour is in some ways a loss to art, and, strange as this may sound from a painter's lips, leads to inferiority. The Parthenon, the Erechtheum, could have gained nothing or very little by the addition of colour; the Byzantine architecture stands in need of purity and elevation of form. The research of the natural has dealt destruction to sculpture. Expression, as in the *Laocoon* or the marbles of Pergamos, destroys grandeur and beauty of expression; and works of that tendency cannot be mentioned in the same breath as the *Venus of Milo*, or the sculpture of the Parthenon, where all is passive. The Middle Ages, with their love for life and

man, began with the soul and produced painters above all. We have followed their lead, drawing closer to nature still; and it must be admitted that sculpture is no longer the leading art, as it undoubtedly was in antiquity, although in many instances, through tradition or for monumental purposes, we may still produce some very commendable sculpture. But it is a distinguishing feature of our age that we seek human individuality rather than symbol, and symbol being the soul of sculpture, its loss is detrimental to the art. But, to go beyond portraiture, the painter has at his command a still higher expression of art—flights to which no sculptor can aspire. I refer to those grand compositions of which the Sistine Chapel, by Michel Angelo, and the *Stanza*, by Raphael, are the highest examples. Next in order to these monumental works must be classed the picture proper, of which many examples, however, belong to the same category as the above. Pictures may be considered as the outcome of a change in the nature of art protection, Church and State having made way for the private individual, a necessary result of modern progress, especially in England, which owes its grandeur and freedom in a large measure to the development of individual action and power. But, although everybody does not possess a monument which may be decorated, everybody has wall-space sufficient to hang a picture on; thus small paintings have come into request, and are perhaps more so now than ever. That the grandeur of art has suffered by this is undeniable, but in all other senses it has been developed by this universal spreading of its influence: in any case the field of operation has become much larger. Landscape-painting above all, an essentially modern branch of pictorial art, and one in which our own painters have excelled, owes its development, if not its existence, to this state of things. We modern men and women love to breathe the open air, can find a poem in a sunset, a sunrise, a calm sea, or a storm; and we have painters who are nobly inspired by subjects which in former times would not have been classed among those belonging to the high realms of art. From the passion and loveliness of human beings, we have come to understand the passion and loveliness of nature; and in this new field daily triumphs are performed. Since the days of Holbein and Vandyke our national art has made great strides; our masters hold their own in every place. When the Continent was disturbed by Classicism and other tendencies, we suffered less from their influence. It was the teaching of our great portrait-painters that produced the Romanticism which Bonington transplanted into France; and, as I once heard Daubigny himself say, it was our landscape-painters that taught the French how to interpret nature. Let us proceed on this high road. Work, study, and put all the forces to the front, in order that we may become what we ought to be—the very first.

#### Encouragement of Local Art.

Mr. J. Towers, in his paper on this subject, said he included under local art not only the art produced by painters residing in Liverpool, but also the work of those artists who, though residing at a distance, were Liverpool men, and made this city the centre towards which they turned for support and encouragement in their work. A Liverpool school of painters—well trained, industrious, earnest, and enthusiastic in their work, supported by liberal and judicious patronage, and guided by the just and generous criticism of men of culture and refinement—would add to the reputation of Liverpool as a great art centre. At present the Liverpool painters were not deficient in natural ability, and if encouragement and fair play was given to them the city would reap the benefit in becoming the home of a Liverpool school of painters, of whom their fellow-citizens might be justly proud. But an artist may be well trained, may possess ability, and may be fortunate in having his works well placed at the exhibitions, and yet, if he lack a purchaser, unless he be a man of independent means, he would be unable to advance in his profession. For in art, as in other things, nothing could be done without money. This raised the question, How can our wealthy men best make use of the means at their command to encourage local art? He thought they could best do this by being liberal with their patronage towards those artists who showed by their pictures that they were really striving to do good and conscientious work, and that any encouragement they received would not be thrown away, but might be the means of enabling them to do greater things. Commissions might be given to local artists to paint portraits or landscape views, or to illustrate subjects suited to the brush of the painter.

Mr. Bruce said that he objected to the term used in the paper, "local art," for art was not local: it was a provincial patriotism to attempt to localise art. Art belonged to the whole world; it was not of any country, or of any one particular school; it was above and beyond all that.

Mr. Wardlaw Laing said that the title of the paper would have been more appropriate if it had been "Encouragement of Local Artists." The great point they had to consider and strive after was to remedy the want of appreciation on the part of those for whom art was supplied; they wanted to make the

whole body of the public appreciate art, just as in the days of Greek art the whole of the people appreciated the artistic beauties around them. He did not believe that art would flourish unless the artist himself was brought into constant contact with the persons for whom the art was produced.

#### Cultivation of the Love of Art.

Mr. James Patterson read a paper, in which he said there was something surely wrong in the system of education at the present time, when they found that the popular feeling had become perverted, and that the intelligent appreciation of the really beautiful was rare, while ugliness in sight and sound and speech was quietly acquiesced in. The unqualified wrong-headedness of current misunderstanding of art questions must be attributed to the arrogance and ignorance of many of those who consider themselves the only competent authorities on the subject. The degradation of political life in the United States was largely attributed to the abstention of the intellectual from its commonplace everyday struggles. Might not a parallel be found in the abuses which tarnished the art life of this country? For the attitude of the general public was the result of the filtration downwards of the ultimate decisions of cultivated men and artists. The present exhibitions of pictures were practically valueless as sources of education, and to the general unthinking public they were injurious, for they visited such exhibitions to be amused, or at the best greatly interested; and amongst the good, bad, and indifferent pictures in a gallery there was the danger of their choosing the two latter, and neglecting the former. The spirit of art was not dead, could never die, and they could all, however quietly, contribute towards keeping it alive in their own day. Let them take pride in their profession, and scorn every temptation that would sully its high aims. Art should not be a luxury or fad for men of means and leisure, but a great factor in the elevation of a people, rendering life not only fair and beautiful, but memorable to the end of time. Let them look forward to and strive for the day when ugliness will have become an impossibility, and when a thing without beauty will be regarded as a foul lie.

#### SCULPTURE AT THE ART CONGRESS.

THE section of Sculpture was under the presidency of Mr. Arthur Gilbert, A.R.A. At the first meeting on Monday, he said he considered that the direction of the deliberations in the section should be rather towards determining how they might serve the interests of the plastic art, not so much from the statuary's point of view as from that of its application to the production of those objects of everyday use to which they must look to encourage the taste for beauty, and cultivate it to such a degree that the plea of utility should no longer be tolerated as an excuse for its absence, nor accepted as its substitute. It was the object of the Association under whose auspices they were met, to help to bring about that prosperity and welfare of the arts—fine and applied—in our country, which to other countries, in every age, had been their greatest and most lasting glory. He expressed the disappointment they must all feel at the absence of Mr. Watts, R.A., whose long, faithful, and earnest career in the service of art had already borne fruit, and would in time to come call forth the gratitude of his countrymen for the position his efforts, as painter, poet, and sculptor, would entitle this country to take with those countries whose art traditions were older, and whose advantages had been greater. He then read a communication he had received from Mr. Watts.

#### Necessity of a National Effort to Popularise Art.

In his letter, Mr. Watts said he regretted that want of health prevented him from being present on so interesting an occasion, and said he should like to let his fellow-members of the Association know how largely his sympathies were with them and that true service to art which he believed this movement was likely to render. The importance of making the aims and principles of art more generally understood could not be overestimated, and if by these meetings the already considerable body of lay workers could be increased, it might be regarded as one of the most hopeful signs of the age. All over the world joy in beauty as an instinct was coming to an end, as in our country—crushed by the wheels of machinery and forgotten in the competition for wealth. There was a time when temple, dwelling-house, or workshop gave to any surroundings, however beautiful, the additional beauty of human interest; now, our factories, our villas, and our cottages were sores upon the face of nature. "Trees is ornaments, and we don't want no ornaments," was the answer made to the Laureate's remonstrance against cutting down some fine old trees which, by a little care, might easily have been spared to be the delight of the dwellers in the ugly villa then being constructed. To prove that this answer, though ignorant, is typical of the spirit of the age, he might refer to Royal Windsor, from whose terraces one looked with astonishment at the desecration of one

of the loveliest spots of England, and in one of the loveliest reaches of the Thames, by a bridge as ugly as it was possible to make it. While the eye of the modern man was denied so much real and ennobling pleasure, the vitality of art also languished to extinction. They should make a stand against the notion that art, as an expression of ideas, emotions, or pleasures, should be left to professors alone. It was formerly a natural expression of impulses, as much naturally used as limbs were still used; now it was as though these natural means were never to be employed excepting by paid agents. It should be as much the object of those who had influence to retain and develop the natural sources of interest and outlets of often little comprehended impulses, as to encourage physical exercises. The stumbling-block to the English was the practical; everything that did not present the idea of immediate advantage seemed to be impractical. "Man shall not live by bread alone." Never was a saying more profoundly wise, even when applied to material conditions; never a truth so little comprehended by the practical mind. For this reason he gladly hailed the accounts of the ever-increasing band of volunteer labourers, endeavouring by all possible means to open the eyes and minds of the people to a knowledge of this forgotten pleasure; teaching the boys and girls of our villages and towns to take a delight in some simple artistic occupation, showing them the beauty of a sweep of landscape, or the grace to be found in the lines of a coil of rope. Till the love of beauty was once more alive amongst us there could be little hope for art; it was a universal language; everything we used or wore was an expression of it or absence of it. The art that existed only in pictures and statues was like the religion kept only for Sundays. To all work which had for its object the rooting of art amongst us he felt sure this Association would give the greatest possible stimulus. The task of the professors of art was a difficult one. They were in the position of a poet told to write on some noble theme in the language of the slums. Painters and sculptors are asked to perpetuate noble and gracious lives, while their portraits were at once deprived of both these qualities by a costume ignoble and ungraceful in every line. The criticism they had to encounter, too, was often that of ignorance, the work itself suffering from the numerous drawbacks arising out of the system of modern exhibition. Altogether, to those who considered the matter, the difficulties of art and the ambiguous position it now occupied awakened many depressing reflections. In the midst of these hindrances the artist much needed the encouragement of fellowship, and of being reminded that he was giving his life to a noble and beautiful work, worthy of all his heart's love, worthy of his first thought in the morning and of his last at night. Whether it was that his special talent enabled him to stand as an interpreter of what was loveliest in nature or highest in man; or whether it was that the world was made merry by the wit and humour of his pencil, or thoughtful by its suggestive irony; or whether it was that he spoke to the imagination as a poet in language as noble, as forcible, as suggestive; or whether it was that his genius led him to do what had been done in civilisations that had passed away, and wrote in bronze or marble the most abiding record of what was best and noblest in his age. He felt very strongly that our days of political prosperity and power were passing away, and that the future would know us better from the impress, they left by moral character, intellectual efforts, by poetry and by art, than by wealth and political position.

#### The Importance of Sculpture in Civilisation.

Mr. George Simonds read a paper in which he said that in dealing with this subject he would have to speak of the conditions which constituted a state of civilisation, of how those conditions arose, of what influences accelerated or retarded their development, and lastly of what share art, and more particularly sculpture, had in their development. It was the object of his paper to show that art was not a toy or plaything, and that sculpture was not a mere luxury for the rich, nor even a superfluity that humanity could well do without. He maintained, on the contrary, that sculpture in some form was a necessity to civilised man, and that art was, if not civilisation itself, at least the strongest civilising power; yes, stronger even than religion, for art was not stained with the crimes of an Inquisition, nor had her influence ever been exerted to check the development and freedom of thought. Yet, so thankless and so blind had mankind become that art was slighted and neglected, and people prided themselves chiefly in what they were pleased to call their modern progress in civilisation. These possessions, these luxuries of modern civilisation, did not in themselves tend to elevate mankind, to make man's life purer or better, but merely to enable him to travel faster and to live with greater bodily ease. Our civilisation was but a varnish; our masses, aye, and most of our classes—were but savages at heart. It was said, "Scratch the Russian and you will find the Tartar;" he believed they might with equal truth say, "Scratch the Englishman and you will find the savage." They tried the

wrong thing when they thought to cure the evil by book-teaching and school boards. A little knowledge was a dangerous thing, and they were distributing this amongst a populace discontented with their condition and envious of their neighbours. They did not try to make their lives better by giving them art, and by teaching them how much that was good and lovely this world contained. Museums, galleries, and art collections of all sorts were very good in their way, but they did not reach the masses of the people. They needed for their refinement and education out-of-door art. They wanted sculpture in all their public places, parks, and gardens; not only monumental work but ideal work—fountains and statues. It was nonsense to say that the climate forbade it, or that the people would not appreciate it. They would appreciate sculpture if they had the chance, and then there would be less brutality and crime about. The lower classes loved beautiful buildings and statues, but they rarely got a chance of seeing them. The museums, galleries, and the like did not reach the labouring classes. It was in vain to open them freely, unless they opened them on Sundays. How could a man who had worked hard all day go to see works of art in the evening? They must place beautiful objects in the people's way. He believed that money spent in flowers and plants for our public parks was laid out at as good if not at better interest than that spent on school boards. Although he had no objection to the latter, he did not see why, if they went in for compulsory education, they should not make freehand drawing part of it. By doing this they would diminish the number of professional artists, since then every boy who could draw would no longer be considered a heaven-born genius, and thrust by his admiring friends into a profession for which he was never by nature intended. If they taught children to read books, why, with equal justice, should they not teach them to read works of art, and to express themselves in lines as well as in letters?

Mr. James M. Hay took exception to Mr. Simonds' remark—not with regard to the opening of art galleries and museums on Sundays, because that was a fair subject for debate—but a remark which was a disfigurement of a very excellent paper, namely, "that art was a greater civiliser even than religion itself." Were it the time or place he should have no hesitation in discussing that point with Mr. Simonds; but there were hundreds in this city far abler than he (Mr. Hay) was to take up that question. He considered it a most serious remark to make.

The Rev. Canon Warr deplored the appearance even of conflict between science, art, and religion. He looked upon all these gifts as coming from one source, and it was most dangerous to put one among the other. He should have been better pleased with the reader of the paper had he omitted the expression referred to, for he doubted very much whether there were many in that room who would accept it.

Mr. Simonds, in reply, said he should be grieved if any words of his should be construed into an attack upon religion. It was not his intention to imply that there was not future salvation, or that the immortality of the soul could be better insured by art than by religion. These were questions which every man must settle for himself. All he said was that the influence of art on civilisation had been greater than that of religion. Art was founded before religion was ever heard of, because savage man and the most degraded nations had no religion, but they had begun by art. He did not wish to hurt the susceptibilities of anybody, and he apologised sincerely, but he should be hypocritical if he retreated from the position which he had claimed for art and its civilising power.

#### Modern Renaissance in Sculpture.

Mr. Onslow Ford, A.R.A., read a paper on this subject. He referred to the fact that sculpture in this country was regaining its proper position amongst us, and was, happily, no longer a dead art in England. This being so, the question was, how this Renaissance was to be turned to the best advantage by the nation, by municipal bodies, and by artists themselves. An infinite amount of work remained to be accomplished, and untiring efforts should be made to impress the importance of sculpture upon the people and those who represented them. He spoke in ironical terms of the proceedings of municipal bodies when about to erect a statue or a monument to departed worth, and he thought that when money was bequeathed for the purpose of erecting a public statue, it would be the best course to pursue to empower his executors to look after the matter, to select a good artist, leave him unfettered, and thus escape the tender mercies of a committee. Very often when a body of men formed themselves into a committee for the erection of a monument, they appeared, oddly enough, to fancy that the very fact of their position converted them at once into judges of art, and, imbued with this astounding idea, they harassed the poor artists in all sorts of ways. If the artist hinted that he could get on much better if left to his own unfettered discretion, he was met with the answer that the committee were responsible to the subscribers. This might be so, but a committee was responsible not only to the subscribers,

but to the country; and when the artist was selected the responsibility shifted from them, and rested solely on the shoulders of the artist. Many a good work had been spoiled by the meddling and muddling interference of committees. He would suggest that one member of a committee instead of twelve or more should be left to deal with an artist when he had been selected. He recommended limited competition, rather in preference to open competition, and in conclusion spoke of what was required to make a good sculptor.

Mr. John Brett, A.R.A., said he regarded sculpture properly as a branch of architecture, and that architecture ought to have sculpture in mind. That was characteristic of the first Greek period. Until they could persuade architects to take the sculpture indoors in this climate they would have a very poor time of it, for they must live out in the cold. When the architect employed the sculptor as his chief workman they would get on in the cultivation of sculpture. They were meeting in Liverpool, which was the Venice of modern Europe. Let them consider what this "Venice" would leave to its descendants in the way of sculpture. In the small concert-hall of St. George's Hall they noticed certain virgins placed to sustain the balcony. The principal indoor feature of that room was sculpture. There were two virgins, and they were so choice and beautiful that it was thought worth while to repeat them at least twenty times. That showed the fertility of sculpture in these days. The architect, whoever he was, had the good sense to think that sculpture should form an important element in his conception, and he found his only resource with these two unfortunate virgins.

Mr. Simonds said that competition was a sore subject with all sculptors. They would not exaggerate if they said that they could defy committees to point to the existence in modern times of a successful competition, simply because the object of the discussion had been to get a lot of work done without payment for it. No man of reputation in these days would compete, because competitions had been so disgracefully managed that it was not worth his while to do so.

The Rev. Canon Warr said that until they could educate the masses art would have very little influence upon them. A great deal was being done to elevate the labouring classes to that point when they would be able really to understand and consequently to appreciate the great works of art that adorned that gallery and other public buildings.

### THE MUSEUM SECTION OF THE ART CONGRESS.

MR. E. RIMBAULT DIBDIN read a paper entitled "A Contribution towards the Art History of Liverpool," in which he said that the art history of Liverpool did not reach back into the far-distant past, and included no record of anything supremely memorable or epoch-making; yet it was much more interesting and important than was generally imagined, and when it came to be adequately chronicled would be found to vie with that of any other provincial town in this country.

Mr. Charles Dyall, curator of the Walker Art Gallery, read a paper on "Do Picture Exhibitions Promote or Impede the Progress of Art?" He said it might seem strange that in this age of picture exhibitions it should be thought necessary to discuss the question, but Mr. Frederic Harrison, in the *Nineteenth Century*, had asserted that all that had been done by exhibitions was a huge mistake, and that instead of promoting true art they were hampering and impeding its progress. Whatever might be said by adverse critics of its constitution and management, it was certain that the Royal Academy had recognised, fostered, and brought into prominence the English school of painters at a time when our nation was aroused as it had never been before to the far-reaching, elevating, and refining influence of pictorial art. Its annual exhibitions had aroused emulation and rivalry among artists, and made a knowledge of art a social necessity; to be ignorant of its operations was to be out of touch with the world of intellect. It had so enormously increased the desire for possessing pictures that its methods had been followed and imitated in every direction, both in the metropolis and the principal provincial towns. Never was there a time when art was so prominent in the everyday life of the people. Replying to the criticism of Mr. Harrison, who would reduce the painter's themes to a limited number, Mr. Dyall said that if we were to discontinue our large exhibitions, and hang only a small number of works selected as being noble, traditional, and beautiful, who was to select them, and who would select the selectors? Were the pictures to be painted in accordance with academic rules, or were they to be broad or pre-Raphaelite, realistic or impressionist? Public exhibitions, if they were to succeed, must be organised in a catholic spirit; the management must be capable of seeing and recognising whatever was good in every kind of art.

Mr. W. M. Conway read a paper on "Reproductions of

Ancient Works of Art for Municipal Museums." Having enumerated the materials which were at hand by which institutions desirous to make a representative collection of reproductions of the art of the past could do so, such as plaster casts, photographs, heliogravure, electrotype, &c., Mr. Conway said he should like to see, side by side with a collection of casts, photographs of the pictures and drawings of all the great masters, accurately grouped and arranged. He would also like to see photographs of all the great buildings in the world arranged according to style and period, reproductions of the goldsmith's art and of gems, from those of Babylon to the latest results of the gem engraver's art, and reproductions of the marvellous medals made in all periods of the world's history.

### APPLIED ART AT THE ART CONGRESS.

MR. G. H. GARRAWAY read a paper on "The Liverpool Art-Workers' Guild." He said his object was to champion those vital truths which he knew to be necessary. Rents were gradually lowering, and new houses were now built as cheaply as possible, without any expense of original artistic decoration; for, although there were architects of taste and capacity, they rarely turned their attention to building houses for any but large financiers. The usual mode of building houses was the merest application of ascertained cheap-builder methods, requiring much knowledge of the tricks of the trade, and also how much discomfort and inconvenience the public will put up with and yet pay rent for. He considered it monstrous that so many gentlemen and ladies should be content to live in such ugly houses. The miseries that an artist had to put up with were a huge, careless, indifferent public; a violent and most unscrupulous competition for the favour of a few wealthy persons; cliques of critics, theorists, and literary-minded persons with a mania for archæology. This would be seen in full force at picture exhibitions—a collection of pictures as at a fair, and the public went there as to a circus or a pantomime. Those exhibitions were gradually ruining the arts; they were tending to produce a type of artist half-tradesman, half-charlatan, a thousand times more dangerous to the arts than the uneducated crowd itself. These were the facts, and if a favourable turn were not taken the arts of the country would be ruined. There was a constant flux and reflux of works by Englishmen and foreigners from London through the provinces, this being upheld by the prejudice that everything from London must be good, and that there was no talent in the provinces; that artists were like horses running for cups and plates, and those should be patronised who were most popular. To remedy that state of affairs young people should be taught to recognise that on entering on a life of art they were open to many rebuts. Let them live as economically as possible, and so fit themselves for the struggle. The Guild desired that patrons of arts should take a little counsel with them as to what was best to be done. The Guild had also desired him to say they did not think there was sufficient municipal encouragement of the fine arts in their city. He would console himself in the immense sadness which these thoughts brought with them if he had inspired some Englishmen with the desire to help the Liverpool Art-Workers' Guild to apply remedies proportioned to so great evils.

### A School for Artistic Handicrafts.

Mr. H. B. Bare then read a paper upon "A School for the Artistic Handicrafts." He referred to the lamentable want of any systematic cultivation of the decorative arts, and said that the chief object in view to remedy this state of things should be to obtain for our craftsmen the highest cultivation in the decorative manual arts, as distinguished from those manufactures in which machinery performed the principal part, to train the designer and the worker to the fullest extent, and, through the improvement in their productions, eventually to elevate the public taste. The problem was how to bring the decorative arts out of their present disorganised and feeble condition into conformity with the parent art of architecture. It seemed to be essential that their efforts should be in the direction of re-establishing unity between the arts, and this could best be done by the adoption of some form of instruction which should combine the studio, the lecture hall, and the workshop with a study of literature and of contemporary science. Notwithstanding the provision at the Liverpool College of the Victoria University of a considerable portion of the educational machinery needed for this system of training, and notwithstanding the remarkable progress made at that institution, yet it must be incomplete until it had provided for the higher and specialised education in the arts as liberally as for the branches of literature and science. Its Roscoe chair of art met the general requirements of a liberal education, but it was not intended to provide exhaustive training in special branches. What was needed was the endowment of a chair of architecture and the allied arts. With such an endowment there would be little doubt of the practicability of including a school for the crafts which were in

natural alliance with architecture. Mr. Bare then proceeded to describe the course through which he had suggested the student of architecture and the craftsman should be led. He afterwards said that it was much to be regretted that the original intention of holding an exhibition of decorative art work in that building—the Walker Art Gallery—during the congress had not been adhered to, and he hoped that the Corporation would afford every opportunity for periodic displays of local art upon the lines laid down for the recent Arts and Crafts Exhibition in London, where the main fact to be observed was the introduction of the names of the artist and worker, which were—and very properly so—attached to the exhibit. He contended it was as legitimate a demand on the part of the producer of a good piece of furniture, wood-carving, metalwork, pottery, mosaic, &c., that his name should be upon it as that the artist should sign the work hung on the walls of our picture galleries. In conclusion Mr. Bare said that the necessity could not be too frequently urged for the establishment in the larger provincial cities of the kingdom of museums of industrial art, which were in every way as important as the collection of pictures in public galleries for elevating the public taste. If the principle of a really national scheme of education in the arts and crafts was admitted, it must be allowed that it was insufficient to centralise our collections of specimens at South Kensington, magnificent and complete though that exhibition might be. It was a decentralising system that appeared to be most required. He sincerely hoped that some strong united effort would be made to improve effectively the position of the arts and crafts in Liverpool. That would be a worthy outcome of the congress, if nothing more were done.

The following resolution was adopted:—"That in the opinion of this congress, it is desirable that largely increased facilities should be afforded for the distribution of photographs, or copies by other processes of art motives and examples for the use of local museums, and all schools and art classes throughout the kingdom at low prices; these examples to include the best works of industrial art in our local museums; also and especially, from continental and Oriental sources; and that the President of the congress be requested to convey this resolution to the Vice-President of the Council of Education, with a view to this suggestion being carried into effect by the Department of Science and Art."

#### EDINBURGH ARCHITECTURAL ASSOCIATION.

AT last week's meeting of the Edinburgh Association, Mr. David Macgibbon, architect, read a paper entitled "The Castles of the Western Highlands and Islands of Scotland." After a short account of the periods into which Scottish civil architecture might be divided, attention was drawn to the large number of castles of the first period (or 13th century) still preserved in this region, and the value of these in connection with the early history of Scottish architecture, comparatively few specimens of that age being left in the more populous parts of the country. The origin of these castles was then considered, and the light thrown upon them by the general history of the Highlands and Islands, and the conclusion drawn was that they were erected by the Royal authority, and held by a custodian appointed by the Crown. The internal evidence of the buildings pointed to their belonging to the 13th century, when the islands became part of Scotland, and when the use of stone and mortar was introduced in castle building. Plans and views of Mingary, Duart, Castle Tirim, Castle Swin, Skipness, Urquhart, and a number of other castles of the 13th century, were exhibited and explained. Numerous other examples corresponding with the various styles on the mainland were illustrated and explained, showing that the Scottish style was universal over the whole country, including the isles, for a period of 500 years. It was also limited to Scotland, and was eminently a national style, and as such well worthy of preservation and imitation. At the close a vote of thanks was accorded to the lecturer.

#### GENERAL.

**The Empress Frederick** has purchased several panels which were produced in the Windsor Works, one being the marriage scene from "Much Ado about Nothing," designed by Mr. H. A. Bone.

**Mr. G. A. Storey's** picture, *The Violinist*, has been presented to the Corporation Art Gallery by the Goldsmiths' Company.

**Mr. Charles Bird** has completed two etchings of the Lauders and Blackader's crypts in Glasgow Cathedral.

**A New Institute**, comprising reading-room, lecture-room, recreation-room, &c., has been opened at Winhill, having been built at a cost of about 1,500*l.*, by Messrs. Lowe & Sons, from plans prepared by Messrs. Osborn & Reading, of Birmingham.

**A Memorial** to the late Archdeacon of Stafford, to take the form of an alabaster recumbent effigy, is to be placed in Lichfield Cathedral. The vicar of St. Mary's, Lichfield, brother to the late Sir G. G. Scott, R.A., has been appointed his successor.

**Sir E. Watkin** has given 100 guineas towards the cost of painted glass for the large east window of Hythe parish church, in Kent, which will be designed by Mr. Pearson, R.A.

**A Stained-glass Window** is being placed at the east end of St. Mary's Church, Crumpsall, in memory of the late Bishop Fraser.

**The Committee** appointed to arrange for a suitable memorial to the late Hon. F. J. Tollemache, at Grantham, have decided to invite designs and tenders for a bronze statue from 7 feet to 9 feet high. The statue is to be fixed upon a pedestal or fountain 17 feet in height.

**Sir Edward Green** has given 500*l.* to the Wakefield Industrial and Fine Art Institution, a cheque for which Lady Green presented to the president, Mr. Bruce, after distributing the prizes to the successful students of the Art School on Tuesday evening.

**The Parish Church**, Stony Stanton, has been reopened after renovation and the building of a new north aisle, under the direction of Mr. W. B. Smith, architect, London.

**A Scheme of Decoration**, after the designs of Mr. A. E. Lloyd Oswell, architect, has been carried out in Middleton-in-Chirbury parish church, by Messrs. Williams & Son, of Shrewsbury.

**A Mission Church** is proposed to be built at Rochester as a memorial of the late Canon Conway, who, when vicar of St. Nicholas, Rochester, built and endowed the church of Holy Trinity at a cost of 13,000*l.*

**A Reredos** has been placed in Christ Church, Willaston. The panels are filled with evangelistic and other symbols. It was designed by Mr. David Walker, architect.

**Ratby Parish Church** has been refloored and resealed, dry rot having made its appearance in the flooring and benches after the restoration of the church a few years ago, and which was said to be caused by the want of underground ventilation.

**The Oxford University Authorities** have renewed, for a further term of three years, the grant of 100*l.* a year which was made towards the maintenance of the British School of Archaeology at Athens. Besides this a sum of 160*l.* is to be spent on providing extra fittings for the Ashmolean Museum, and 200*l.* more on repairing the conservatories in the Botanical Gardens.

**The Tower of Bridgerule Church**, Devon, was struck by lightning last week, and fissured from the top nearly to the ground. An iron rod, running from the flag-pole to the corner pinnacle, is supposed to have attracted the lightning.

**The late Mr. George Nelson**, sculptor, London—who was an assistant of Musgrave Watson—has bequeathed to the Carlisle School of Art a collection of his own works, for the furtherance of art in his native city. The valuation for probate purposes is 41*l.* 13*s.*

**A Constitutional Club** erected in Scarborough, from the plans of Mr. H. A. Cheers, of Twickenham,—selected in competition—has been completed. The building is in Queen Anne style, of red brick and Whitby stone.

**The Restoration** of Shobrooke Church, Devon, which was initiated nine years ago, has been completed under the direction of Mr. Ashworth, of Exeter.

**The Foundation-stone** of a new church at Starbeck, of which Mr. Sheard, of Harrogate, is the honorary architect, was laid on Friday last.

**A Permanent Building** for the Free Church at Springburn, N.B., is to be proceeded with at once, in place of the iron church at present used.

**New Racing Stables** have been erected at Newmarket for Mr. Blundell Maple, and special attention has been paid to the ventilation. Messrs. Robert Boyle & Sons' latest-improved patent self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

**Mr. W. G. Penty**, architect, last week gave a lecture in the York Institute on the archaeology and art of ancient Egypt. The student, he said, experienced the greatest difficulty in comprehending a civilisation whose antiquity was so far removed from Greece and Rome that in comparison the latter appeared grouped with modern nations. Egypt was the birthplace of art, and its works formed the foundation for subsequent artistic development.

**The Duke of Devonshire** has notified his intention of handing over to the Buxton Local Board the Serpentine Walks, a favourite public resort in the town, conditionally upon their being kept in repair by the town's authority. The Duke has also given sufficient land to form a handsome approach to the new town-hall, free library, and public offices. The value of the gift amounts to about 4,000*l.*

A Business Supplement

# The Contract Reporter.

to The Architect.

LONDON, DECEMBER 7, 1888.

# IMPROVED FLAT BRICK FIRE-PROOF FLOORS.

No. 1.—Longitudinal Section.

No. 2.—Longitudinal Section.

## NO THRUST ON WALLS.

The BEST as well as the CHEAPEST Fire-proof Floors yet introduced.

THEY are constructed with purpose-made hard-burnt bricks, with specially moulded dovetail projections, forming a mechanical key to hold the plaster protecting the iron, and provided with wedge joints throughout, forming the most compact and solid floor known.

Experiments show a resistance to load and impact greater than furnished by the ordinary concrete floors. No thrust is transmitted to the walls, as in all arched construction, the walls being tied in and strengthened.

The floors are practically noiseless, the different densities of the concrete, brick and plaster, with the air space above, intercepting the sound vibrations.

The depth of the finished floor is 6 to 9 inches only, and when the saving on this head is taken into account, the cost does not exceed that of the ordinary combustible timber floor of corresponding strength.

# HOMAN & RODGERS,

Engineers and Patentees,

17 GRACECHURCH ST., LONDON, E.C., & 13 DAWSON ST., MANCHESTER.

**TRADE NOTES.**THE tender of Messrs. Parker & Sharpe, to complete the new lock on the Foss for 3,482*l.*, has been accepted by the York City Council.

An award of 37,621*l.* has been given by the arbitrator, Mr. W. Beadel, M.P., in regard of the claim of Captain Park-Yates against the Manchester Ship Canal Company for his residential estate in Cheshire, near the mouth of the Mersey. The claim was for 73,490*l.*, and the evidence of professional gentlemen supported that amount. The witnesses for the Manchester Ship Canal Company considered 25,515*l.* was sufficient.

THE arbitration case, Kirk & Randall v. East and West India Dock Company, which was supposed to be interminable, has reached the stage of deposit of award by Sir Frederick Bramwell. The contractors claimed for extra works, and damages for suspending them in the execution of the works, and when the proceedings had reached a certain stage an effort was made by the defendants to restrict the arbitrator's right, to receive evidence. This involved action in several courts, and, finally, the proceedings were ordered to be continued as before. The arbitrator now decides in favour of the contractors. A sum of 195,000*l.* is awarded on account of works, besides an amount for damages which has yet to be

assessed, the contractors' claim being 300,000*l.* for the wrongful suspension of works. The Dock Company will also have to pay costs. Messrs. Kirk & Randall were unjustly treated, and deserve all the compensation they are likely to receive. It will be a pity if enough money is not to be found to pay them.

INDIARUBBER is the latest device introduced for street-paving in Germany, and it is to be put down in one of the Berlin streets as an experiment. It is not, however, a novelty, having been used in this country for years on a small scale for deadening sound under archways, as at the St. Pancras Midland Hotel.

A PROPOSAL on the part of some leading gentlemen in Dumbarton to erect a cottage hospital for the burgh has taken practical form, a site having been purchased in the Townend district for the new institution. Plans have been prepared by Mr. Thomson, architect, George Street, Edinburgh, and offers are now being accepted for the work.

IN a competition for the best scheme for sewerage and sewage disposal for Otley, in Yorkshire, the premium has been equally divided between Mr. W. H. Radford, C.E., of Nottingham, and Messrs. Brierly & Holt, of Manchester. Mr. Radford was the successful competitor also at Newhaven, Beacontorpe, and Macclesfield.

AT the last meeting of the Douglas Town Commissioners, it was resolved to erect new abattoirs on a site known as the "Lake Yard," situated near the railway station. Plans submitted in open competition by Mr. Thomas W. Cubbon, architect, of Birkenhead and Douglas, were unanimously recommended by the committee and adopted by the Board. The scheme comprises eight private slaughter-houses, one public slaughter-house, with the necessary lairage accommodation attached, and large cooling-house or dead meat market; also accommodation for pig slaughtering and dressing. The estimated cost of the scheme, including site, amounts to about 7,000*l.*

THE furnacemen at Barrow decided on Tuesday to resume work, their wages to be based on a sliding scale, and operations have been resumed at the iron and steel works. Thirteen blast furnaces have been damped down owing to the strike, and 3,000 men have been idle.

THE Water and Sewerage Committee have presented a report to the Worcester Town Council, in which they state that if the present source of water supply is to be retained it appears necessary to carry out works at an estimated cost of 26,000*l.*

They prefer obtaining a substituted supply for Burcot, but, failing that, it would be desirable to sink a trial bore-hole at a site near Aston Fields.

MISS GRACE HAWTHORNE has arranged with Mr. Wilson Barrett to produce a new play at the Princess's on the termination of the run of "Hands across the Sea." The engagement with Mr. Barrett is limited to twelve weeks. Miss Grace Hawthorne will herself appear in weekly matinées during Mr. Barrett's engagement. There is no truth in the rumour that Miss Hawthorne proposes to part with the lease of the Princess's Theatre, which she has recently renewed for a further term of five years. The patrons of this theatre will be pleased to hear that Mr. W. W. Kelly will still retain the reins of management.

MESSRS. JONES & ATTWOOD, of Stourbridge, have just finished heating by their patent system—Wesleyan Chapel, Bradley, near Wolverhampton; Kingswinford Church, near Dudley; Annington Church, Tamworth; Coseley Church, Salop; Congregational Chapel, Lye, Stourbridge; Wesleyan Chapel, Brades, near Birmingham; Town Hall, Darlaston; Municipal Buildings, Bridgenorth; Basford Prison, Nottingham.

A DESIRE has been expressed for the fixing of a carillon-machine in the belfry of the parish church, Walsall, the cost of which will be about 250*l.* Towards this one well-known townsman has offered to contribute a substantial sum.

THE usual monthly meeting of the Leeds Association of Foremen Engineers and Draughtsmen was held on Thursday last week, when the President (Mr. J. C. Moorhouse) read an interesting paper on "A Comparison of English and American Workshop Practice." The paper was followed by a discussion.

ANOTHER large stone has been removed from the Pilkington Stone Quarry, Horwich, worked by Messrs. Dent & Sons. The quarry is noted for its huge ashlar. The stone is 13 feet 9 inches long, 5 feet 4 inches broad, and 6½ feet thick, and weighs 30 tons.

A LOCAL Government Board inquiry has been held at the Village Hall, Weybridge, by Colonel Walter Mardon Ducat, R.E., with whom was General Scott, metropolitan water inspector, in regard to the application of the Rural Sanitary Authority for the Chertsey Union for sanction to borrow 15,000*l.* for works of sewerage and sewage disposal for the parish of Weybridge and the special drainage district of Oatlands. Considerable interest was manifested in the inquiry.

## NOTES ON NOVELTIES.

IN building a house, perhaps no article is, or should be, of greater importance both to the comfort of the tenant, and to the peace of mind of the landlord, than the cooking range. Yet how often do we find that this most necessary and useful article is both stinted in price, and put in without the slightest regard to the convenience of the future tenant. The cry of cheapness is more frequently carried to excess in the stoves and ranges than in any other portion of the building; true, there are many contractors and builders who ignore the cheap range, and are willing to pay a few pounds more to have the cooking department of the house as perfect as possible. A cheap range means continual repairs and renewals, so that in the end the balance is on the wrong side of the ledger as regards cheapness. Perhaps one reason of the indifference so often shown in selecting a cooking range is the uniform character of this article. There has always been the strong and light, the common and well-finished range; but still the principle in all has been the same, and it is only during late years that inventors have turned their attention to improving our cooking appliances. Although large sums have been subscribed to be given as prizes for fuel-economising stoves, very little progress has been made by manufacturers in meeting this want. We have, however, lately seen in operation a newly-patented cooking range, called the "Herald," made by Messrs. Russell & Sons, of Derby, who have not only had a life-long experience in this special class of trade, but who are now among the largest cooking-range manufacturers in the country; their numerous patents and specialties are well known to every member of the trade. The "Herald," their last patent, is a lifting fire range; that is, instead of using the old-fashioned false bottom grate, they lift the fire up to its work by means of a movable bottom grate. The special feature about Messrs. Russell & Sons' patent bottom grate is that there are no working parts in the fire, so that it is impossible for it to get out of order. It consists of a loose bottom grate resting upon two brackets at the back, and is kept in position whilst working up and down by bearing against two curved guides on the front of the fire-bar frame. It is perfectly loose and unattached to any part of the stove. This plan allows the fire front to be flat not curved, as in some lifting fire ranges, and roasting or roasting before the fire is consequently not interfered with. The movement of the grate is so perfectly simple and easy to work that it at once commends itself to any practical person. We

are assured that half the fuel generally used in a range can be saved by this patent. Another advantage in this range is that in summer time the kitchen is kept much cooler and is quite free from the intense heat of the ordinary close range. It is also a combined open and close fire. When the oven is not in use, the range can at once be thrown into an open fire, a great saving of fuel being the result, besides having a cheerful appearance. The great cause of complaint in the old close fire range, of not getting the bottom of the oven properly heated, is a thing of the past as regards the "Herald" range, for by a simple arrangement part of the heat is conducted direct to the bottom of the oven without first passing over the top, consequently a uniform heat is obtained all round the oven. From the simplicity of its arrangement and the great advantages it undoubtedly possesses for saving fuel, we have no doubt there will be an extensive sale for the "Herald" when it becomes better known.

## THE ARCHITECTURAL ASSOCIATION.

THE fourth ordinary meeting of the Association took place on Tuesday evening, Mr. H. D. Appleton, F.R.I.B.A., president, in the chair.

The following gentlemen were elected members:—Messrs. G. D. Curtis, J. P. Cooper, A. C. Breder, T. P. Simpson, S. W. Cranfield, H. T. Cooper, G. H. C. Cole, H. J. Potter, R. Savage, E. J. Wellman, C. F. Devitt, J. L. Williams, W. L. Lucas, W. H. Barton, T. Jenner, S. Gluckstein, J. E. Capell, M. J. Culligan, H. A. Dives, R. A. J. Paxton, H. C. M. White, V. Vaughan, W. H. Finch, E. B. Wetenhall, J. S. Millbourne, W. Stainer, H. J. Gamble, and C. S. Stone.

Mr. J. L. Robinson, R.H.A., then gave a lecture, which was illustrated with photographs shown by the aid of lime-light. He prefaced this with some introductory remarks, as follows:—

## Irish Architecture.

Mr. ROBINSON said:—Although the remains of ancient architecture now existing in Ireland are few in number and singularly devoid of detail, yet a great amount of interest attaches to them as records of the condition of the country at different periods of its history. The sepulchral tumuli which abound are the only evidence which now exists of the Tuatha de Danaans, a race which inhabited Ireland until the invasion of the Milesians about 1,000 B.C. Some of these tumuli, which

are scattered along the banks of the River Boyne from Drogheda to Slane, are of large size. The most notable is New Grange, an artificial mound covering a long passage of upright stones, with lintels over, leading to a cruciform chamber, about 30 feet high. Some of the stones composing the passage, and those at the entrance, are covered with ornament of the simplest character, such as lozenges, zigzags, and concentric circles. The mound at New Grange is surrounded by a circle of monoliths, placed at equal distances apart. The entire internal arrangement of this tumuli bears a great resemblance to the pyramids of Egypt. Cromlechs are also very plentiful, as well as stones with ogham inscriptions, which consist in notches cut on the edges of the stones. It is probable that, with very few exceptions, timber formed the principal material used in the construction of dwellings until a comparatively recent period. The earliest examples of masonry are of a cyclopean character, the stones used being of large size, closely fitted together, and the doors and windows have sloping jambs and lintels over.

Some of the churches at Glendalough and Clonmacnoise partake of this character. In the west, rude huts of dry masonry, like beehives, are to be seen, which were used as dwellings by hermits in early Christian times. In Keeling Church, a small building attributed by Petrie to the sixth century, is an Etruscan door with a Greek cross cut in relief on the soffit of the lintel. There are several examples of stone-roofed churches or houses, the best known being St. Columba's house at Kells, St. Kelvin's house at Glendalough, and Cormack's chapel at Cashel.

The development from the lintel is easily traced; first, the lintel is scooped out to form an arch over the open, then the arch is formed of three stones, and later on many stones are used. In the same way the earlier doors and windows have square jambs without ornament; then a fillet was worked on the edge, or bead, and by degrees the ornament developed until it culminated in the beautiful and distinctive ornament to be seen at Ardger, Glendalough, Clonmacnoise, Cashel, &c. The great peculiarity of Irish—that is, pre-Norman—architecture, is the large use of interlaced ornament, which was carried at the same time to such perfection in metalwork and in illuminated manuscripts. The same ornament occurs in the doors, &c., of the later round towers, and forms the principal decoration of the crosses.

Some attention has lately been bestowed on the fact that large numbers of crosses, or rather fragments of crosses,

covered with interlaced ornament, are to be found in Scotland and the Midland counties. This is easily accounted for by the fact that, from the sixth to the tenth centuries, when the entire of Europe was overrun by barbarians, Ireland kept alight the lamp of learning and Christianity, and sent her missionaries to all parts of the world, whilst the noblest families of Europe sent their sons to be educated at the renowned colleges of Ireland. Hence the missionaries brought artificers and their art along with them, and their Celtic ornament is to be traced at Iona, Lindisfarne, through England, Normandy, Switzerland, and many other parts of Europe.

The round towers are, I may say, peculiar to Ireland, and have given rise to several theories about their origin. Some say they were built by the Phœnicians, others by the Danes, or by the Fire-worshippers, or that they were Buddhist temples. Dr. Petrie was the first to show that they were decidedly of Christian origin, by analysing each theory and exposing its weak points and contradictions. He also proved that they are never found unconnected with ancient ecclesiastical foundations; that their architectural styles exhibit no features or peculiarities not found in the original churches with which they are locally connected, when such remain; that on several of them Christian emblems are observable, and others display in the details a style of architecture universally acknowledged to be of Christian origin; and finally that they possess, invariably, architectural features not found in any building in Ireland ascertained to be of Pagan times. He then proves that they were used as belfries and watch-towers, and also as places of refuge in times of danger, the doors being placed at such a height from the ground as to favour such a theory, which is supported by the many entries in the Irish annals of forays by the Danes on the churches, and that the clergy took refuge in the Cloicktheagh, a round tower. The crosses are also almost peculiar to Ireland. Several of them are covered with figures representing Scripture subjects, the *Last Judgment* often appearing at the junction of the arms around the crucifixion. The old churches are all of very small size, the cathedral at Glendalough measuring 37 feet by 55 feet in length. The development of the ornament is easily traced in the different examples which still exist. King Urmac's chapel at Cashel, which was finished in the year 1134, is the latest and most ornate example of the style. All the arches are semicircular, the piers or pilasters square and covered with ornament, and the roof or panel vault with ribs dividing each bay. There is no doubt that but for the Anglo-Norman invasion there was

every probability of the development of a style of architecture differing in material respects from the rest of Europe.

The architectural result of the Anglo-Norman invasion was that the invaders imported their notions of architectural taste with them, and all subsequent buildings in Ireland show similar detail to English architecture; but owing to the hardness of the building stones and the poverty and unrest of the country, the detail is generally poor and the mouldings few and shallow. All the abbeys and churches were built so as to stand a siege, and some of them differ little in appearance from feudal castles.

Notwithstanding the change in architectural style, it is surprising that the interlaced ornament still survives, and is to be seen in the capitals at Pierpoint Abbey, and in the masons' marks at Cashel, Holy Cross, and many other buildings down to the sixteenth century. The fifteenth century must have been a very flourishing time for the building trade, as most of the abbeys which now stand—whether in ruins or not—show details of that period. Any Elizabethan work is generally poor, and the only details are large mullioned windows. During the eighteenth century, and particularly during the last eighteen years, a large number of public buildings were erected in Dublin in the Classic style. The Parliament House, Four Courts, and Custom House are buildings of which any city may be proud.

The above remarks are merely introductory, as I now intend to exhibit a number of photographs done by myself of buildings from the earliest periods, and trust that you will excuse any shortcomings in the views, as, being only an amateur, my work will not bear comparison with that of men who devote themselves wholly to it as a pursuit.

A most interesting series of views were then shown, including many of the old crosses and round towers. The number of views amounted to 106 in all, and amply testified to Mr. Robinson's skill in using the photographic camera.

The proceedings terminated by a vote of thanks passed to Mr. Robinson on the proposition of Mr. S. F. Clarkson, seconded by Mr. M. B. Adams.

#### GLASGOW INSTITUTE OF ARCHITECTS.

A QUARTERLY general meeting of the Glasgow Institute of Architects was held on Thursday in last week, when there was a large attendance of members. The president, Mr.

John Gordon, occupied the chair. Mr. David Thomson called the attention of members to the facilities which the Technical College and School of Art offered for the training of their pupils and assistants. There were now excellent courses of instruction in the form of evening classes for building construction, hygiene, and drawing available for young men at a very low scale of fees, and he thought members of the Institute would do well to encourage their assistants to make use of them. Mr. Honeyman said he was glad Mr. Thomson had referred to this matter. A word or two from them to their young men, especially before the college session commenced, might have an excellent effect, and induce some to avail themselves of opportunities which might never recur. Young men should remember that the certificates of the Technical College were taken into account by the Institute in awarding their certificate, and he might also remind them that they will not now be able to join the Royal Institute of British Architects without passing an examination, and this would be greatly facilitated by attendance at the classes of the college and the School of Art, which was practically affiliated with it. The attendance at the class of building construction this session was very satisfactory, but he was sorry to say that the attendance at the class of hygiene was small. He had no doubt, however, that they might easily excite more interest in these classes among their apprentices and young men. Mr. James Thomson submitted a report from the committee on the subject of rules for the measurement of wrightwork, recommending the Institute to homologate the action of its delegates, to approve the rules for measuring wrightwork, and to authorise the secretary to issue them to members. The adoption of the report and its recommendations was proposed by Mr. Bryden, seconded by Mr. Skirving, and unanimously agreed to. Certain suggestions relative to the measurement of plumberwork by the Plumbers' Association were received and remitted to the committee on rules of measurement. A letter was read from Mr. William Clark, for many years an active member of the Institute, cordially thanking the members for the honour that had been conferred on him on his election as an honorary member. Mr. T. L. Watson handed in the report of a paper read before the Philosophical Society of Wellington, New Zealand, by Mr. Thomas Turnbull, F.R.I.B.A., and member of the Glasgow Institute of Architects, on the subject of "Building Construction with reference to Earthquakes." Mr. Turnbull was cordially thanked for the communication. Mr. W. F. Salmon called attention to the want of an architectural museum in Glasgow, and proposed that some step should be taken with

a view to the formation of a collection of architectural drawings, photographs, and other objects. The matter was remitted to a committee. Mr. D. Thomson made some suggestions regarding the membership of the Institute, and a committee was appointed to consider them.

### THE GORDON STATUE.

THE following interesting communication [from Mr. Hamo Thornycroft, R.A., appears in the *Magazine of Art* for this month :—

At first it was proposed that the statue should be placed as a pendant to that of Havelock—the statue of Napier to be removed farther back in the Square to make room. To this removal there proved to be some serious opposition. This I did not regret, as the task of making a pendant to the Havelock monument did not fill me with delight; for I am strongly of opinion that the scale of this statue is entirely wrong, and detrimental to the effect of the Square. I preferred rather having a site farther back in the Square for the Gordon, where I could have a freer hand, and could aim at making a statue whose scale, at any rate, should be in proper proportion to those buildings around most worthy of consideration, namely, the National Gallery (which is really a beautiful building), the church of St. Martin's, and the College of Physicians. That portrait-statues in public places should have a relation to the buildings in their immediate neighbourhood, and not to abnormal structures, such as the Nelson column, is, I think, not to be questioned. We have removed one monster to the wastes of Aldershot, and there are still others which might, at any rate, be reduced in scale, if we are ever to beautify London. It is a vain hope, perhaps, but I should like to live to see a smaller copy of Foley's Prince Consort placed under the golden canopy in Kensington Gardens in lieu of the gilded Colossus now there.

The Gordon monument consists of a bronze statue of the hero, 10 feet 6 inches high, and a lofty decorated pedestal, containing on two sides of the shaft bronze panels in low relief. The subjects are allegories—the one "Fortitude and Faith," and the other "Charity and Justice." Gordon appears as an English staff officer, wearing a patrol jacket, but without belts, sword, or weapon of any kind, except his famous short rattan cane, or "Wand of Victory," as it came to be called during his

celebrated China campaign. Weapons he never wore, even in his most daring undertakings. His arms are almost in the folded position, but the right hand is raised up to the chin, while the left firmly grasps a Bible beneath his right elbow. Slung at his back is a binocular field-glass. He stands firmly on the right foot, the other is raised on a broken cannon. This latter I introduced to give a military environment to the figure, and at the same time to express his dislike to bloodshed and war—as if, so to speak, he would wish to put his heel upon it. The whole aspect of the statue I wished to be resolute, solitary, but not sad. I have had the advice and assistance of Mr. Waterhouse in the design of the pedestal. This is composed of hard Derbyshire limestone, known as Hopton Wood stone, which, unlike the depressing, interminable, never-changing grey granite all around, lends itself to the sculptor's chisel, so that the cap, or cornice of the pedestal is here carved with appropriate ornament and scroll, giving the names of Gordon's famous campaigns and victories. The upper pedestal, or sub-plinth, to the statue, is enriched with bronze wreaths and festoons of honour to the man above. The proximity of the high terrace at the back required that the pedestal should be high, so that the whole monument measures 29 feet in height.

### PURIFICATION OF THE CLYDE.

At the last meeting of the Health Committee of the Glasgow Town Council, Bailie Crawford submitted a report respecting a scheme for the purification of the River Clyde. In carrying out a remit from the committee to visit various towns in connection with "cleansing" matters, he said he had, as directed, taken the opportunity of observing the methods of sewage purification in operation at the several places visited. He had been at Birmingham, Nottingham, Croydon, Berlin, Paris and other places, and at none of them had he seen anything to alter his opinion expressed to the committee some time ago—that it was quite practicable to purify, and at the same time utilise, the sewage of Glasgow, by irrigating the plains of the Cart and Gryffe, called in earlier times Strathgryffe. By irrigation he did not mean that the sewage was simply to flow over the land, but was to be filtered through it—practically, the process which had been termed "Intermittent downward filtration." After alluding to former schemes in Glasgow for dealing with the sewage, and referring to the measures adopted in the towns he had visited, Bailie Crawford went on to say

## CONTRACTORS TO H.M. GOVERNMENT.

INTERNATIONAL HEALTH AND OTHER EXHIBITIONS—MEDALS AWARDED FOR

# LEGGOTT'S PATENT ADJUSTMENT

CONTINUOUS OPENER.

SILENS.

THE SILENS, for Fanlights, Skylights, &c. Is admitted to be the best ever put before the Public. Can be adapted to any kind of window. Size and height of window no object.

From 4/3 each.

The WILMOS is worked with a rod or endless cord. It is extremely neat, and can be fixed to open either top or bottom, inwards or outwards; no cutting away of frame required. When worked with a rod is most efficient for Public Buildings, as the key can be loose. For Price Lists, Illustrations, and Testimonials, write as below.

For Continuous and other Lights, Estimates given.

WILMOS.

NO CUTTING AWAY OF FRAME REQUIRED.

### TESTIMONIAL.

SIRS,—I have pleasure in testifying that I have used Leggott's Silens Adjustments for various buildings to high skylights, fanlights, and top parts of windows, and in every case they gave satisfaction. They are secure in whatever position, whether the window is open or closed, and are quite simple and workable in their action. I prefer them to any other that I have seen or used for the above-mentioned purposes.

Messrs. W. & R. LEGGOTT, Bradford.

BANGOR: N. Wales: Sept. 14, 1885.

I remain, yours obediently,

R. DAVIES Architect.

Considerably Reduced Price List, November 1, 1887.

TELEGRAPHIC ADDRESS—"SILENS BRADFORD."

that the natural collecting point for the sewage of Glasgow seemed to be immediately below Govan. From this the sewage would be forced through cast-iron pipes direct to the most suitable points on the irrigation farm which would be established. Or an alternate, or, perhaps, the better plan would be to have the rising mains delivering the sewage into a large covered conduit formed about 50 feet above ordnance datum, and to a length of about 1½ miles on the ridge from North Hillington to Arkleston. Thence it would gravitate through pipes syphoning under the White Cart, &c., into the open main carriers on the farm. The whole cost of the works he estimated would be covered by 880,000*l.*, with an additional sum of 620,000*l.* for the proposed irrigation farm (about 4,500 acres) and stock. On the working of the farm he was prepared to expect an annual loss of about 6,000*l.*; while the scheme would entail other annual charges amounting to 38,300*l.*—making an annual amount of about 44,300*l.* to be provided by the rates. This large sum, spread over the estimated rental of "Greater Glasgow" (4,386,833*l.*), would, he said, be covered by a rate rather less than 2½*d.* per *l.*; and he proposes that the total capital expenditure on the interception works, &c., be reduced in sixty-six years.

#### NEW CITY OF LONDON COURT.

THE new City of London Court was opened on Thursday by the Lord Mayor in state, attended by Mr. Alderman and Sheriff Gray and Mr. Sheriff Newton. It is situated on the south side of Guildhall Buildings and on the west side of Basinghall Street, and occupies the site of the old Court buildings, the old Land Tax Offices, and the "Tap" of the Guildhall Tavern. When the lease of 84 Basinghall Street expires, which will happen in the course of a few years, the building will be extended (says the *City Press*) over those premises, and it may be mentioned that the plans have been designed with that view. The ground floor consists of the offices for the staff of clerks and bailiffs, the former of whom are increasing from time to time in order to cope with the large growth of the business; while on the upper floor, to the west, is placed the Judges' Court, some 45 feet by 26 feet, to the east the Registrar's Court, 36 feet by 26 feet, each with a private room attached, and approached by a separate stair and entrance. The principal and public entrance is in the middle of the façade to Guildhall Buildings, and opens into a spacious hall

which gives access, right and left, to the offices on the ground floor, and to a staircase leading to the courts on the floor above. The lavatories, furnace, record-rooms, &c., are in the basement. The building has been designed in the late Gothic style of architecture, which was also adopted for the Guildhall Library and the new Council Chamber, in order to harmonise with the ancient Guildhall, which was built, as is well known, in the early part of the fifteenth century. The external moulded work is in Portland stone, with grey granite plinths, while the walling is of Kentish ragstone.

Turning more particularly to the internal arrangements—the hall and staircase, the latter of which is very wide, and presents an excellent appearance, are of Bath stone, the hand-rail of polished Hopton Wood marble; the open roof of oak, with ribs springing from four griffins, also of oak. The two upper windows are of tinted glass, sprinkled with a pattern of roses and crowns. The south window contains the armorial bearings of the Lord Mayor, Mr. B. S. Foster MacGeagh, J.P., the chairman of the Law and City Courts Committee, and of Mr. H. H. Bridgman, architect, the late chairman of the committee. In the north window are the arms of the City, and of Mr. Alderman and Sheriff Grey and Mr. Sheriff Newton. Mention should be made of the fact that the judges and registrar's courts are particularly well lighted. The flooring of the upper and lower halls is of Deispecker's marble mosaic. The appearance presented by the two courts is quite in keeping with the purpose for which they are intended. In the judges' court the members of the legal profession will enter by doors on either side, while ample accommodation is made for the public at the back of the court. The courts have panelled wainscot ceilings, from which are suspended brass gaseliers; while over the judge's chair at the west end of his court is a canopy of wainscot, French polished. The seats, doors, fittings, &c., are also of wainscot. The building has been erected in just over twelve months, the foundation-stone having been laid by the Lord Chancellor on November 23, 1887. Mr. Andrew Murray, F.R.I.B.A., the architect, deserves much praise for such an admirably suitable building. The general contractor for the building and fittings was Mr. J. Morter, of Stratford; for the heating apparatus, Messrs. J. Wontner Smith, Gray & Co.; for the brass gaseliers and brackets, Messrs. G. Forrest & Sons; and for the judges' and other chairs, Messrs. Cooper & Holt. Mr. Merifield has acted as clerk of the works during the construction of the building.

FIFTEENTH YEAR OF PUBLICATION. NOW READY.

## "THE ARCHITECT'S DIARY" FOR 1889.

Specially prepared for the use of ARCHITECTS, SURVEYORS, and ENGINEERS.

These Publications contain not only the usual Diary, ruled and printed to a particular form, specially adapted for professional use, but, in addition, an Index, a Note-Book, a Rent and Insurance Register, a Cash Book, and a Ledger, with all the usual diary information, and much special matter referring to the various Architects' and Engineers' Associations; a digest of all the Acts passed last Session; contain also cases decided in the Superior Courts of Justice during the legal year, from November 1887 to August 1888 of interest to the Profession; complete list of Metropolitan Surveyors and Districts, with Official and Private Address; Alphabetical Index to the Practical Statutes, Stamp Duties &c., the whole forming in ONE VOLUME A COMPLETE SET OF BOOKS for the YEAR. The Editions are—

No. 12.—One page to a day, size 8½ in. by 5 in., cloth, gilt, 4/6. No. 13.—Two pages a day, size 8½ in. by 5 in., cloth, gilt, 5/6.

## "THE BUILDER'S DIARY" FOR 1889.

Specially prepared for the use of BUILDERS and CONTRACTORS.

No. 11.—Two days on a page, ruled and printed to a special pattern; also contains Bill Register, Note Book, Rent, Insurance, and Mortgage Register, Cash Book, Ledger, and 130 pages of Tables of great value to all engaged in the Building Trades, in all 400 pages, size 8½ by 5, bound, whole cloth, gilt. Indexed, and pagged to end of Diary. Price 4*s.* 6*d.*

"For use in the office of Architects and Builders they are better fitted than any diaries with which we are acquainted."—*The Architect*.

"Messrs. Hudson & Kearns's Diaries need no recommendation save a trial."—*The British Architect*.

"The novel and valuable feature of these Diaries is that each volume forms in itself a complete set of books for the year."—*The Builder*.

"We have used them ourselves throughout the year with much satisfaction, and are glad now to draw attention to the new batch sent us."—*The Building News*.

"The Diaries published by Messrs. Hudson & Kearns are quite unrivalled for convenience and comprehensiveness."—*Building World*.

"These Diaries may be said to have become the Diaries for the professions for which they are issued."—*Illustrated Carpenter and Builder*.

Sole Publishers, HUDSON & KEARNS, 83 Southwark Street, London.

## SHEFFIELD SHIP CANAL.

THE plans and works in connection with the proposed new canal from Sheffield to the sea have been deposited at such places as are required by the Standing Orders of Parliament. Commencing at the Sheffield end of the scheme, it is proposed to take seventy acres of vacant land, mostly belonging to the Duke of Norfolk, near Brightside Lane, and there to construct a dock seventy acres in extent, with quays and all other buildings and appurtenances necessary to the loading and unloading of vessels. In course of time warehouses, docks, and so forth will be erected. The docks will be close to the principal works, where heavy goods are produced. From thence a new and shorter cut will be made through Carbrook, where a considerable quantity of cottage property will be swept away, and on to Tinsley, where it will join the existing canal. Thence it will pass through Rotherham, Mexborough, Swinton, Doncaster, and other populous towns, following the course of the canal belonging to the River Don Navigation Company, and on to Stainforth. At a point near to the Keadby railway junction the canal will join the Stainforth and Keadby canal, and go on to the river Trent and Keadby, where the river is navigable. The canal will be 80 feet wide and 15 feet deep, and will, it is believed, prove a great boon to the heavy industries of the district.

## WEST OF SCOTLAND SANITARY ASSOCIATION.

The annual general meeting of the West of Scotland Sanitary Association was held on Monday afternoon in Glasgow, Sir James King, the Lord Provost, presiding. The seventh annual report by the Council showed that during the year 173 members had resigned and that 170 new members had joined, leaving the membership at September 30 last at 354, being a falling off of three. While the benefits to be derived from the work of the Association were more and more appreciated at a distance, the Council regretted that those benefits were so little appreciated in the city. Many members joined the Association for one year, and obtained more than their money's worth in the form of a minute inspection and detailed report. Satisfied with this, they left the Association to take care of itself for the future. The object of the Association, however, was by yearly examinations to insure that the houses of its members con-

tinued in a sanitary condition. It was also stated that the guarantee fund had been dispensed with this year. The financial statement showed that the receipts had been 728*l.* 5*s.* 11*d.*, and the expenditure 515*l.* 2*s.* 10*d.* Mr. John Ure and Professor M'Call Anderson were among the speakers. Professor Gairdner submitted the list of office-bearers and council, and moved its adoption, which was seconded by Colonel Reid, and approved.

## AMERICAN versus ENGLISH AND ITALIAN LABOUR.

AN interesting discussion is published in a recent number of the American trade journal *Stone*, upon the relative value placed upon American and English labour, under the heading of "Marble and the Tariff." This journal had severely attacked the Mills Bill, which proposed to reduce the tariff on marble by 20 per cent. It pointed out that work which cost 66*¢* 47 dols. in the States could be obtained for 13*¢* 33 dols. in Italy, and that, as a consequence of the tariff, every penny of the difference went into the pockets of the American workmen. This view of the case is opposed by an English firm of marble merchants, Messrs. Arthur Lee & Bros., of Bristol, who affirm that the calculation made as to Italian labour is erroneous, and that the difference should be as between 66*¢* 47 dols. and 34*¢* 26 dols. They further contend that the apparent difference in favour of the American worker is illusory, owing to the high cost of living in the States, and that as a result of free trade in England, the English workman is enabled to live cheaply, while at the same time he has succeeded in beating the Italian on his merits without a tariff. They say, "Our workmen have to compete with the labour of the world; they do so by cutting and contriving, and by a continual improvement of mechanical appliances. What follows? Take our own case; some years ago we manufactured a good deal of monumental work in Italy, now we do most of it in this country, quite as cheaply and of very far better quality. Our men get good wages and live cheaply, but to enable them to do so we are continually improving our mechanical appliances. We are importing rough marble into England, working it here, and re-exporting it to better advantage than by working it in Italy; we therefore find labour for Englishmen which was done by Italians. On the other side we hear of American firms who set up factories in Italy, and employ Italian labourers for work

The "PERFECTUM."

## "PERFECTUM."

In London the above are kept in stock by Messrs. GEORGE WRIGHT & Co., 155 Queen Victoria Street, E.C., who will be pleased to show and explain them to Architects and Contractors.

On view at the Cardiff Exhibition, September and October, and at the Ironmongers and Metal Trades Exhibition, London, November 12 to 24, 1888.

TELEGRAMS—"PERFECTUM," BOLTON.

The "Perfectum" will be exhibited in the Parkes Museum, London, and at the Glasgow Exhibition. Architects can have a Model Free of Cost on application.

See Illustrated Advertisement first week in each month.

## THE BARD. Facsimile of Cartoon by Professor Maillart.

Size, Thirty-six Inches by Twenty-two Inches.

Price One Shilling; free by post, carefully packed inside patent roller, One Shilling and Threepence. May be obtained from all Newsagents or Booksellers, or from the

Publishers, GILBERT WOOD & CO., 175 Strand, London, W.C.

which was once done by Americans. This is the only way in which they can retain a vestige of export trade. We leave it to you to say which course brings most labour to a country." The editor of *Stone* admits that the argument adduced by his correspondents is "plausible," but asks, "What does it matter if the American working-man might under a free trade policy pay less for the necessities of living? Under protection he has undeniably more money to spend, and we assert it as a good principle that it is better to spend a dollar here for what may be obtained for fifty cents in England than to have only the lesser sum to economise on." He goes on to observe that if the Americans had not a home market in which to dispose of their products "we might be put into somewhat similar condition to the English people, who must perforce look outside their own domain for the material to furnish labour with something to do, and other markets than their own in which to dump their products. The American market belongs to the American working man, and in this particular instance of the marble industry, the tariff of fifty per cent. ad valorem on the manufactured article should be increased to as nearly a prohibitive standard as possible, rather than reduced twenty per cent., as the pro-Italian Mills Bill proposes." The effect produced by opinions of this kind upon the fortunes of a party suspected of free-trade leanings can be easily understood.

#### REGISTRATION OF PLUMBERS.

At a meeting held at the Lambeth Polytechnic Institute, the Lord Mayor said that in going through their workshops he was delighted beyond measure to see they had a class for practical plumbing. There was no greater need at the present time than a perfect knowledge of sanitary science. One of the livery companies of the City (the Plumbers' Company) had established a system of registration for plumbers, and at the last examination twenty out of thirty were rejected. It might be asked, Why should plumbers be registered? He would answer, Why should chemists be registered? The object was that they might not poison their neighbours; but where a chemist poisoned one, bad plumbing poisoned fifty. Therefore he said, "Go on with your plumbing classes and your technical schools, and the probability is you will greatly improve the condition in which you live."

#### STEAM-ENGINE EFFICIENCY.

At a meeting of the Society of Engineers, held at Westminster Town Hall on Monday evening, December 3, 1888, Mr. A. T. Walmisley, president, in the chair, a paper was read on "High-pressure Steam and Steam-engine Efficiency" by Mr. W. Worby Beaumont, M.Inst.C.E.

In the first part of the paper attention was again called to the misleading results of the common application of the theory of the perfect engine as a basis for an index to the comparative efficiency of actual engines, working under different conditions and with different pressures. Examples of the reasoning based upon this interpretation of the "Carnot" theorem, or this application of the "Carnot" ratio, were given as showing that it had been common to suppose that the useful limit to steam pressure would be reached at about 200 lbs. or below it. Reasons for expecting very large increase in available work as due to the increase of pressures up to at least 300 lbs. were given, with figures showing the extra work available per extra unit of heat used.

In dealing with the steam-engine as a heat-engine, it was argued that considerations relative to the boiler as the producer of the steam and as the receiver of the hot water rejected by the engine are irrelevant, and, further, that no part of the history of the steam used should be included other than that which begins with the admission of the steam into the cylinder and ends with its emission therefrom.

In estimating the quantity of steam required to perform a given quantity of work, the steam necessary to fill the cylinder at the pressures shown by indicator diagrams was not credited with providing any of the heat necessary for the performance of the work, excepting only the units of heat represented by the difference between the total heat of steam at the initial and at the terminal pressures. In a non-expansive engine the whole of the heat equivalent of the work done would have, according to the paper, to be supplied in addition to that represented by the volume of steam required to fill the cylinder.

This heat was assumed to be supplied by initial condensation, and an object of the paper was to show that the performance of work alone demands sufficient heat to account (with the exception of some very small losses) for the whole of the observed initial cylinder condensation. Proceeding on this thesis it was argued that cylinder condensation apart from this is a very small quantity in the best actual engines, and that it consists mainly in loss of heat by evaporation during exhaust,

ESTABLISHED 1790.

# THE "WASH-OUT" CLOSET

(PATENT).

THREE AWARDS AT THE INTERNATIONAL MEDICAL SANITARY EXHIBITION,  
SOUTH KENSINGTON, 1881.

No. 201.

"How to Drain a House," from a paper by T. MELLARD READE, Esq., C.E. F.R.I.B.A., read before the Liverpool Architectural Society: "I consider the pan-closet objectionable, especially since the introduction of the two-gallon regulating cistern has increased the difficulty of getting the after-flush to fill the pan. The 'container' is usually a reservoir coated with filth, hidden by the pan holding the water in the basin. A basin with a trap at the side or back, called a 'WASH-OUT' basin, is a far better apparatus."

"Improvement on Sanitary Condition of Houses," from a paper by J. CORBETT, Esq., read before the Social Science Congress, Manchester, 1879: "We replace defective Closet Appliances by the simple 'WASH-OUT CLOSET,' which is of white earthenware, without any valve, and so perfectly self-cleansing as to require very little attention."

Extract from a letter by "M. O. H.," a Medical Officer of Health, *Daily Telegraph*, September 22, 1880: "The Local Government Board forbids the use of these pan-closets. . . . They may be easily replaced by one of the 'WASH-OUT' CLOSET Basins."

Extract from a lecture by W. EASSIE, Esq., C.E., at the International Health Exhibition, May 28, 1884: "A cleanly 'WASH-OUT' Flushing Rim Basin in connection with a small Flushing Tank overhead which merely required a touch of the depending chain and ring to liberate the whole contents."

No. 250.

Special Cheap Pattern.

REFUSE IMITATIONS. See that the Registered Trade Mark "Wash-Out" is printed inside the Basin.  
NONE ARE GENUINE WITHOUT THIS.

and of slight losses due to radiation and conduction, and to clearance space not filled at initial pressure by compression. From this it was concluded—

1. That as small a portion of the cylinder capacity as possible should be subject to exhaust influences.
2. That it follows from 1 that multiple stage expansion is necessary with the high pressures that are advisable, and that high speeds of rotation ought to be attended with economy.

### THE CITY MARKETS.

At last week's meeting of the Court of Common Council, the Markets Committee submitted plans for the appropriation of a portion of the land north of Charterhouse Street as a site for a fruit and vegetable market, at an estimated cost, for works, of 15,500*l*. The committee had had an interview with the tenants of Farringdon Market, who explained the practical requirements of their trade in view of a new market, viz., a level area, a large space for each tenant, no building involving masonry, but simply a roof on the columns, with shelves, and moderate rents. They accordingly instructed the City architect to prepare a plan of a cheap and light structure, which he had done. The site proposed to be occupied abutted on Charterhouse Street and Farringdon Road. The building would cost 15,500*l*. The scheme seemed so thoroughly in harmony with the views of the trade, as regarded its general character and moderate cost, that the committee had no hesitation in looking favourably upon it, more especially as it brought into rental land which had remained for some years unproductive. As soon as a new fruit and vegetable market was provided, Farringdon Market would be discontinued, and the site disposed of. It was estimated the annual expenses of the market would be 3,645*l*., and that the rentals and tolls would bring in 4,657*l*., leaving a surplus income of 1,012*l*.

Mr. Perkins moved the adoption of the report, and stated that the area proposed to be utilised had been vacant for twenty-five years. The land would give them an extra area for market space of nearly 60,000 cubic feet. Everyone was agreed that the present Farringdon Market, being built on the slope of a hill, was excessively inconvenient, and all the tenants would remove, he believed, to the new market when completed.

Mr. Hicks urged that the proposed buildings would be a disgrace to the Corporation, which had already expended large sums in market experiments. For instance, the Fish Market

in Farringdon Street had involved an annual loss of 10,000*l*. to the Corporation. They had recently opened another fish market in the same locality, but they could not seriously believe that it would be a success. He moved, as an amendment, "That the report do lie upon the table."

Mr. Deputy Bedford said in a few months they would have the new County Council, and it might be that they would take in hand the establishment of markets in various parts of London. If so, the Corporation would then discover that they had spent a vast sum uselessly.

After a long discussion the amendment was negatived by 108 votes to 28, and the report was agreed to.

The Markets Committee brought up another report on the vacant land opposite Billingsgate Market about to be acquired from the Commissioners of Sewers. They proposed that a building should be erected with 38 stalls on the ground level, with 15 vaults in the basement, and with 43 offices in the upper floors. The cost would be 19,215*l*., and the annual expenses 4,514*l*., while the rentals would amount to 5,245*l*., leaving a margin of profit of 731*l*. This would much increase the accommodation for the fish trade at Billingsgate.

The report was adopted, and the Court adjourned.

### PRIVATE BILL LEGISLATION.

ON the evening of Friday in last week, in accordance with the provisions of the Standing Orders, plans in relation to schemes of Private Bill legislation which it is intended to promote in the next session of Parliament, were deposited at the Private Bill Office of the House of Commons, having reference to 161 measures, of which 47 related to railways, 14 to tramways, 54 to miscellaneous schemes, and 46 were Provisional Orders. The following is a list of the Bills:—Great Northern Railway, South Eastern Railway, London, Chatham and Dover Railway, Midland and South Western Junction Railway, North West Central Railway, Corporation of London (Tower Bridge), Midland Railway, London and North Western Railway, Metropolitan Railway, Great Western Railway, North Eastern Railway, Volunteer National Rifle Ranges and Camp (Cannock Chase), London Imperial Docks Bill, Metropolitan Improvements, Monumental Chapel (Westminster Abbey), Rickmansworth and Uxbridge Valley Water; Southend-on-Sea Harbour; Harpenden Water, Provisional Order; Kensington and Knightsbridge Electric Lighting Company, Provisional Order; Lea

### THE PARIS EXHIBITION.

A MEETING of the Executive Council of the British Section of the Paris Exhibition, 1889, was held last week at the Mansion House. Alderman Sir Polydore de Keyser presided. Mr. H. Trueman Wood, one of the secretaries, reported that the whole of the space placed at the disposal of the British Section had been allotted among exhibitors. Various colonies had desired to participate, but the most urgent appeals to the French authorities had failed in obtaining any extension of the original amount of space granted. The committee, however, had been able to devote a considerable space in the south-east part of the section to Victoria and New Zealand, as well as one of the three galleries on the Quai d'Orsay, which had been allotted to Great Britain and the colonies. Space in another of these galleries has been handed over to the Cape of Good Hope. It was believed that the Kimberley diamond mines would have an exhibit in the precincts of the Exhibition. With regard to the printing of the catalogue and guide, the tender of Messrs. W. Clowes & Sons, Limited, had been accepted. There was every likelihood of an adequate representation of British art, and promises of support had been received from many leading artists. Considerable progress had been made in the decoration of the British Section under the honorary superintendence of Mr. J. H. Donaldson, a member of the committee. Many of

the provincial municipalities were contributing banners and flags for the purposes of decoration. The Lord Mayor (Mr. Alderman Whitehead) had become president of the General Committee, Sir P. de Keyser, his predecessor, continuing to act as chairman and treasurer of the Executive Council. The committees for the Social Economy and Anthropological Sections had been at work, and expected as many exhibits as the French authorities would be able to find room for, an independent committee had been formed for a Retrospective Exhibition of the means of transport, and there seemed every reason to believe that the result of the operations of the committee would also be thoroughly satisfactory. Sir Frederick Leighton, P.R.A., adverting to the Fine Art Section, said in view of the fact that in Paris in 1878 England had been represented very worthily in matters of art, and obtained very considerable renown and reputation, which had been maintained by the Art Sections at Munich and Berlin, it would be damaging if British art was not well and excellently represented next year. The expenses of freight, insurance, and other matters would be about 3,000*l.* if any number of works of art of the highest class were lent for exhibition, and he hoped the Council could see their way to increasing their grant for the Art Section. Sir J. D. Linton, P.R.I., concurred in the views of Sir F. Leighton, and the Council unanimously voted, including previous grants and donations, 2,000*l.* towards the expenses of the Art Section. Sir F. Leighton said with that sum they could make a commencement, and could found an appeal not only to the public for donations, but to collectors and artists for the loan of suitable works of art. On the motion of Mr. Ernest Hart, seconded by Mr. Woodall, M.P., it was resolved unanimously, "That Sir Polydore de Keyser be nominated executive president, and Mr. H. Trueman Wood commissaire délégué of the Council in Paris."

### GOVERNMENT BUILDING CONTRACTS.

A DEPUTATION from the London United Trades' Committee of Carpenters and Joiners waited upon Mr. Plunket, the First Commissioner of Works, at the House of Commons on Tuesday, to urge upon him the desirability of certain alterations in the rules at present in force with respect to Government building contracts. Mr. Broadhurst, M.P., who introduced the deputation, said they wanted specially to call the attention of the

First Commissioner to the practice of subletting portions of contracts, a practice which led to the evils of the sweating system. The Trades' Committee proposed that in future Government contracts the contractors should engage not to sublet portions of the work to middlemen; that they should not allow their men to work overtime save in cases of urgency, and that they should pay the standard rate of wages and otherwise conform to the rules and customs of the building trade. Mr. Plunket, in reply, said he could not undertake to regulate the rate of wages to be paid by the contractors, but that he would endeavour to prevent as far as possible the system of subletting.

#### BUILDERS' BENEVOLENT INSTITUTION.

THE forty-first anniversary dinner in aid of the funds of this institution was held on Thursday, the 29th ult., at Carpenters' Hall, London Wall. Mr. J. Howard Colls, president of the Institution, occupying the chair. The President was supported by Mr. Alfred Rosher (Master of the Carpenters' Company), Mr. John Aird, M.P., Mr. H. H. Bartlett, Mr. Arthur Lucas, Sir George Chubb, Professor Roger Smith, Mr. Thomas Blashill, Mr. Chatfield Clarke, Mr. Rickman, Mr. Banister Fletcher, Mr. G. Burt, Colonel Stanley Bird, and other friends of the Institution, the company numbering about 230.

The Chairman gave the toast of "Her Majesty the Queen, the Prince and Princess of Wales, and the rest of the Royal Family."

Mr. J. W. Hobbs (Mayor of Croydon) gave "The Army and Navy," Major Brutton replying for the army and navy, and Colonel Stanley Bird for the Reserve forces.

Sir George Chubb gave "The Houses of Parliament," for which Mr. John Aird, M.P., responded.

The Chairman, in proposing the toast of the evening, "Success to the Builders' Benevolent Institution," remarked that charitable institutions were the pride of this country and the envy of other nations. The builders had not been backward in the good work, and he was proud to say that the most distinguished members of the trade had been his predecessors in the chair. The members of all professions and trades were liable to misfortune and reverse. The business of a builder was deeply interesting, and there was nothing monotonous about it except Saturday night. It was a manufactory of a vast number of articles, subject to difficulties above and below

ground. Sometimes intense heat brought its calamities, and at other times intense frost or too much wind. The responsibility of the builder never ceased, but lasted as long as he lived, for if anything went wrong he was sure to hear of it. He did not wish to say anything against the professions with which they were associated. As a rule, nothing could be fairer than the treatment the builders received at their hands; but, at the same time, many of the claims on this institution came from men who had suffered from the exceptions to that rule—from the architect who had supplied defective drawings, and from the specifications of inefficient quantity surveyors. Any of those troubles were likely to lead to disaster, and they ought to remember that however stable they might feel at the moment, any one of them might encounter such a calamity as would make them glad to apply for help to such a society as the Builders' Benevolent Institution. The institution had been suffering from the depression of trade, and the subscriptions had fallen off. If there was a time when an institution like this ought to be supported it was in times of depression, and he asked them to support him, and show the world that the builders were a benevolent race. The chairman added that, as Mr. George Plucknett, J.P., the hon. treasurer, was not with them that evening, they would simply drink the toast without reply.

The toast was duly honoured.

The Chairman next proposed "The Health of the Carpenters' Company," referring to the kindness of the Company to the building trade, or any branch of it.

Mr. Alfred Rosher, Master of the Carpenters' Company, replied, and remarked that it was the duty of the Company to do what they could for the advancement of the craft.

Mr. Arthur Lucas gave "The Health of the Chairman and President," adding that every one who knew Mr. Howard Colls knew that whatever he undertook he entered into *con amore*, and it would be difficult to find a worthier occupant of the presidential chair.

The toast was cordially received, and the Chairman replied in suitable terms.

Mr. H. H. Bartlett proposed "The Architects and Surveyors." He said the presence of so many members of the professions showed their sympathy with the builders. The work done by the architects of the present day would, he believed, stand comparison with that of any of the great architects of the past. In fact, there was no great thoroughfare in the metropolis in which they could not see works rising

## GRUNDY'S PATENT WARM-AIR VENTILATING FIRE-GRATE.

The novelty, superiority, and advantage of this patent consist in the heating surface being greater than any other Fire-grate introduced to the public. It is very simple in construction, and is made in the form of a Stove, the back of which is semicircular in shape, with gills behind and smoke-nozzle on top, all cast in one piece. The same can be attached to any design of a Register or Stove front. It is very suitable for schools, class-rooms, waiting-rooms, hospitals, offices, dormitories, and dwelling-houses, from the cottage to the mansion. Design and specification post free on application.

#### TESTIMONIALS.

9 Victoria Chambers, Westminster, S.W.

SIR.—I have much pleasure in testifying to the efficiency of your patent warm-air fire-grate. It has been very successful, and given every satisfaction where I have used it.

Yours, &c., JAMES WEIR, F.R.I.B.A.,

To Mr. Grundy, 6 John Street, Bedford Row, W.C.

From Hon. and Rev. G. G. C. TALBOT, M.A., Withington, Cheltenham.

DEAR SIR.—You will be gratified to hear that the school is completely warmed by your new grate. It is the most economical and efficient that I have ever seen.

Mr. John Grundy.

#### ACROSTIC.

Just listen, friends, to what folk say  
Of Grundy's patent warm-air grate,  
How with the fresh air channels they  
Not only warm, but ventilate.

Give wondrous heat, burn little coke,  
Require but slight attention paid,  
Unequal'd for consuming smoke,  
No better grates were ever made.  
Do try just one of Grundy's glo,  
You then will all its merits know.

CORSHAM, WILTS.

Note.—No Connection with the other BATH STONE FIRMS.

around them which must tend to elevate the taste and character of the people. In olden times the architect and surveyor were coupled together; but the less that was the case the better, as the surveyor should hold the balance between the architect and the builder. He coupled with the toast the names of Mr. Chatfeild Clarke and Mr. Rickman.

Mr. Chatfeild Clarke said he believed at times the architects must be looked upon as ogres, but that feeling was passing away, and builders felt they could not trust themselves more comfortably than in the hands of a respectable architect. At the same time the architects never could carry out their works successfully without putting their trust in a responsible and respectable builder. They were, therefore, there in a sort of partnership, and it was a sincere pleasure for him to be present.

Mr. Rickman responded for the surveyors.

Mr. Maton proposed the concluding toast, "The Vice-Presidents, Committee, and Stewards," which was responded to by Messrs. T. F. Ryder and J. T. Bolding.

In the course of the evening subscriptions and donations amounting to 1,053*l.* (of which sum 804*l.* appeared on the President's list) were announced.

### PATENTS.

*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.*

#### APPLICATIONS FOR PATENTS.

17307. Joseph Trickle, for "A self-closing draw-off tap." November 28, 1888.

17311. Amelia Jane Kent, for "Improvements in making india-rubber mats, covering treads of stairs, landings, floorings, and similar wearing surfaces." November 28, 1888.

17351. Robert Bocock, for "Starting a syphon in cistern, the same to be called 'Lindum Syphon Cistern.'" (Complete specification.) November 29, 1888.

17363. James Hargreaves, Thomas Robinson, and John Hargreaves, for "Improvements in the manufacture of cement and in apparatus employed therein." November 29, 1888.

17415. Adolf Katy, for "New or improved blocks for building purposes, and means for constructing the same." November 29, 1888.

17418. John Suttie Stark and Arthur Hodgkin Scarfe, for an "Improved portable telescopic ladder for use as a fire-escape, and for other purposes." November 29, 1888.

17424. James Murrie, for "Improvements in and relating to feed-water mechanism for steam boilers, partly applicable for

## MARION'S PHOTO SUPPLY WAREHOUSE.

**THIS DETECTIVE CAMERA** is in the form of a neat leather despatch box—size 10 by 5 by 6 inches. It takes Plates  $4\frac{1}{2}$  by  $3\frac{1}{4}$ . The one great feature which places it before most other Detective Cameras is that, by means of a mirror, the exact and full-size picture is seen on a screen at the very moment of firing the Shutter, so that the user can always know what he is going to get on his Plate. The Lens is a Rapid Rectilinear, covering well. The Focussing is by Rack and Pinion, the Lens being mounted on a front inside the Camera. There are three Double Slides with the Camera. Price **£8 8s.**

Sole Agents, MARION & CO.

**THIS CAMERA**, as the name implies, is in the form of a book—it therefore can be used secretly, and carries 24 Plates, which are fitted in Metal Sheaths and exposed in rotation. The Lens is of excellent quality, and made from the new Jena Glass, and gives very fine definition and great depth of focus. Price **65s.** each, inclusive of the 24 Sheaths for Plates.

Sole Agents, MARION & CO.

**AMATEUR PHOTO-SETS OR OUTFITS**, complete with Lens, Stand, Plates, Chemicals, Dishes, Lamp, &c. We have a large variety of these all complete, ready for use, with practical instructions. Nonpareil,  $\frac{1}{4}$ -Plate, **30s.**; Students, for 5 by 4 Plate, **50s.**; The Oxford, for  $6\frac{1}{2}$  by  $4\frac{1}{2}$  Plates, **100s.**; The University, for Plates  $8\frac{1}{2}$  by  $6\frac{1}{2}$ , **200s.**; The Engineer's and Builder's Set, for Plates 12 by 10, **£22.** (Fig. 2.)

**THE SUPERIOR SETS**, High-class, good Lenses. These Sets always give satisfaction. For Plate,  $6\frac{1}{2}$  by  $4\frac{1}{2}$ , **£17**;  $8\frac{1}{2}$  by  $6\frac{1}{2}$ , **£20**; 10 by 8, **£28**; 12 by 10, **£34.**

**THE EMPIRE SETS.** Specially prepared to stand any climate. Every article of the best description. Lenses by Voigtlander, Leather Case for Camera. All Complete in Polished Mahogany Box,  $8\frac{1}{2}$  by  $6\frac{1}{2}$ , **£37**; 10 by 8, **£45**; 12 by 10, **£55.**

# THE "THOMAS" LAMP.

Lighting Power with  
ordinary London Sixteen-  
Candle Gas, from tests  
taken by Professor Wm.  
Foster, M.A., L.R.C.S.

No.	
10.	11·4 Candle-power per foot.
11.	12·5           ,,           ,,
12.	12·5           ,,           ,,

These Lamps are made in three  
sizes, Nos. 10, 11, 12.

These Lamps can be obtained through Gasfitters, Ironmongers and  
Merchants. Foreign Orders through Merchants only.

The advantages of this Patent  
over other existing Lamps  
are:—

Small consumption of Gas  
with great Illuminating power.

No possibility of the Burner  
corroding or getting out of  
order, as is the case with other  
generative gas lamps.

The Lamp can be fitted by  
any gasfitter. No fine per-  
forated metal, gauze, or other  
obstructions are used in this  
Patent, as in other lamps which  
are liable to become choked  
through imperfect combustion,  
rendering the lamps smoky and  
useless.

**55 & 56 MINORIES, LONDON, E.C.**

# The Architect.

## THE WEEK.

THE people of Liverpool can be thankful that an influential section of the City Council has negotiated successfully with Sir FREDERICK LEIGHTON for the purchase of his *Captive Andromache*. The President has met the Council in the most generous way. He receives only part payment at present out of the money obtained through the admission fees to the exhibitions, and the remainder will not have to be paid until it is obtained in the same way. The people will thus be enriched by a noble work of art without any cost to them. The picture is well adapted for a public gallery, for students of art can derive invaluable lessons from it. Judging by the remarks in the Council Chamber about the transaction, it is to be feared that some time will have to elapse before the community in general will be able to appreciate the work.

A QUESTION which is now being asked among French architects is why M. EDOUARD CORROYER has been removed from his office of architect at Mont Saint-Michel? Can it be that the officials propose further degradations to the ancient buildings, in which M. CORROYER declines to have any share? The only certainty is that he no longer has charge of Mont Saint-Michel. At the next sitting of the Commission of Historic Monuments his successor will be nominated, for the approval of the Minister. For several years back M. CORROYER has devoted himself to the care of the sea-washed towers, the "Marvel" cloisters, Church, Chamber of the Knights, and other remnants of the age of chivalry, and from the association of the place with English history, he has a claim on the gratitude of Englishmen for his efforts to resist the ruin of the buildings.

AT a meeting of the Council of the Institute of Chartered Accountants in England and Wales, held on Tuesday last, the designs for the erection of a hall and offices, submitted by six architects who had been invited to compete, were considered, with the assistance of Mr. ALFRED WATERHOUSE, R.A., who kindly acted as assessor. The plans forwarded by Mr. JOHN BELCHER, F.R.I.B.A., of 5 Adelaide Place, London Bridge, were unanimously adopted, and Mr. BELCHER was appointed the architect to erect the proposed building. The plans can be seen to-day and to-morrow at 3 Copthall Buildings, E.C. (first floor).

THE Glasgow City Council have decided to take down the Exhibition buildings with the exception of the Fine Art Galleries, which are to be used as a sort of refuge for works which cannot be exhibited in the Galleries in Sauchiehall Street. Some of the members of the Council wished to preserve the buildings in their entirety, but it was difficult to discover any use for them, and in the second place a large sum would need to be expended in order to make them watertight. The construction was not intended to be tested by the rain and storms of the North.

THE rivalry between the Corporation of Leeds and a temporary committee of the inhabitants for the acquirement of the grounds and ruins of Kirkstall Abbey could hardly fail to be without its effect upon the owners of the property. At one time a sum of five thousand pounds could have secured that part of the Cardigan Estates, but after the controversy on the subject, the value has been increased to double the sum. At the sale on Wednesday a reserve price of 10,000*l.* was fixed upon the Kirkstall lot, and the highest bid by the town clerk of Leeds, on the part of the Corporation, was 6,100*l.* If, by any mishap the grounds should be diverted from public use, the Corporation will have to bear the blame. If instead of shilly-shallying over the proposals for purchase, the Corporation had decided to buy, or to abstain from buying, there would be no difficulty now. But no decision was arrived at until a committee was formed in the town, and then a member of

the corporation tried to cut out the newcomers. The trustees of the property utilised the opportunity in the way we have explained, and eventually the people of Leeds will probably have to pay 12,000*l.* to obtain what remains of Kirkstall Abbey.

ALTHOUGH the French people are supposed to take an interest in all forms of art, there is very little concerning architecture to be found in their journals, especially when compared with the articles on painting and sculpture. The Société Centrale des Architectes has tried to bring about a more ample appreciation of the art by instituting a series of conferences, in which art-critics and other writers will take a part. The hall of the Ecole des Beaux-Arts has been lent for the meetings. The first discourse was delivered on Thursday in last week by M. ROGER-BALLU (who is, we understand, a son of the late THEODORE BALLU, the architect of the Hôtel de Ville), on "Contemporary Criticism and Architecture."

WHEN Temple Bar was taken down great care was taken in numbering the stones to correspond with a plan which had been prepared in the city architect's office. But, according to Mr. C. E. PONTING, F.S.A., who had charge of the reconstruction, all the trouble thus taken, however, was rendered futile in consequence of the perishable nature of the medium—probably watercolour—which was used for marking the stones. In the result only two or three out of the entire number had any trace of it left on them after having lain on the ground and been exposed to the weather for ten years. Mr. PONTING says that, with the aid of a staff consisting of a builder, a foreman, a clerk of works, a sculptor, and a band of workmen, he was able to put all the stones which had not perished, and they weighed four hundred tons, in their right places at Theobald's Park.

MR. F. B. BARWELL, the artist who is one of the inspectors of the Science and Art Department, has appealed to his fellow-citizens of Norwich about the state of their art school. Evidently the people take care that they will do nothing to promote the appearance of successors to the CROMES and COTMANS. The art school is at the top of a building, and is too limited in area. The committee have no money to pay for the erection of a better building. Science is in a corresponding condition with art. Mr. BARWELL points out the advantages which are available elsewhere in England, and he pertinently asked the citizens:—"Are you going to confine your youth to the birthplace? Are they not to seek employment elsewhere, and so lighten some of your burdens and responsibilities? Is no fresh industry ever to arise in Norwich? And are not your people likely to be supplanted by the better instructed from other places?" A better argument is found in the statement that the large sums distributed by the Science and Art Department cannot be claimed in Norwich. Finally Mr. BARWELL begs of the people to insist on their representatives in the Town Council, the trustees of their various charities, and other bodies who may have a voice in the matter to throw aside their party or sectarian differences, and work together for a great and salutary object, to confer upon the population at large those permanent and well-proved benefits that the hard-headed people of the North have long ago embraced as essential to their prosperity.

THE French canal system will be greatly changed if the invention of M. MAURICE LEVY of the Institut can be utilised to the extent which is proposed. It consists in the haulage of the barges by endless wire cables, which are to be fixed on both banks of a canal. The barges will be attached to the cables by an apparatus which can be as readily removed. A speed of only two and a half English miles an hour is contemplated, and at that rate the injury to the banks of a canal must be very slight. The cost will be much cheaper than when horses are used. By order of the Council of Ministers an experiment has been tried near Jonville with satisfactory results. M. LEVY does not propose to make any profit out of his scheme, and offers it as a gift to France.

## PROVENCE AND THE RIVIERA.\*

THE fine illustrations of Nîmes and Arles by Mr. NEEDHAM WILSON, in the Architectural Illustration Society's series, may have revealed to many the richness of the south-eastern part of France in Classic remains. Some pictures by Mr. CALDERON have also suggested that the painter will in that part of France find models no less attractive than those of Capri. But, as a rule, strangers do not care much for exploring the country which lies on both sides of the lower reaches of the Rhone. Parisians regard the inhabitants as belonging to a different race, and of late have supposed that the eccentricities of the novelist M. TARTARINI are common to all the descendants of the Provençaux, if not to the whole of the people of the Midi.

A glance at the map will show the accessibility of the south of France to all who could sail along the Mediterranean. Greeks and Romans gained a footing there. It was a colony of Phœnicians who founded Marseilles, and their descendants opened the way to the Romans for the conquest of Gaul. If the Greeks have not left many signs of their architectural skill in France, it is otherwise with the Romans. Looking at the great works which remain, we might imagine that architecture was employed as a means towards the civilisation of the Gauls and the bringing them peaceably under the dominion of the invaders. What other reason can explain the existence of a theatre in Orange which could accommodate at least 7,000 spectators? At Arles was another, and the *Venus* in the Louvre, which was dug up on the site, will by itself suggest the magnificence of the two buildings. Then there were amphitheatres which were still larger in area; one in Nîmes could seat 20,000 spectators. If we suppose that the Roman provinces also contained temples and public buildings which were no less grand than the places for spectacles, we must admire the greatness of a race who tried to conquer barbarism by arts as well as by arms.

It was the good fortune of the district to be endowed with all that art could do at a later time. MACAULAY's schoolboy must remember what the historian wrote about the condition of Provence in the twelfth century. That country, he tells us, was the most flourishing and civilised part of Europe; each of the cities was a little republic, each of the castles was a miniature of the imperial court. There the spirit of chivalry first appeared, as the inseparable associate of art and literature. It is maintained by some French archæologists that Byzantine artists worked in France. If Greeks could find a market for Eastern tapestries in Narbonne and Toulouse, and meet with disciples who were eager to be indoctrinated in mysterious Eastern theories, may we not also suppose that Eastern ideas about architecture and ornamentation spread through Provence, and affected the styles of the architects? One thing is certain, that if we are in search of examples of pure Gothic, there is no use in going to the South for examples of it. But the buildings would be less characteristic if they were marked by more unity of style. All sorts of traditions seem to meet in them, and in cases where unity and severity are sought, they appear to be intended as a corrective of the opposite qualities. There was always more or less independence in that part of France, for it should be remembered that the oldest writer who describes the Albigenes of Provence—GUILLAUME DE PUY LAURENS—admits that they were not all of the same belief about LUCIFER's relation to this world, which they supposed was his creation. Crusades and inquisitions may have had the effect of subduing the people's independence in one way, but it is evident that no force could induce the artists to mould their work entirely on northern models.

It is the interesting district of south-eastern France that forms the subject of Mr. MACGIBBON's book, "The Architecture of Provence and the Riviera." In arranging it he follows topography, that is, he describes the towns in succession as he passed through them. But, unlike the writers of most tourist's books, he divides the descriptions into two parts. Mr. MACGIBBON recognises that in the district there are examples of two distinct styles. He first notices the Classic buildings of the district, and afterwards

those which may be called Gothic. For a student of architecture this arrangement is serviceable, as he is enabled to compare illustrations of a style with more satisfaction than if the two were mixed together. Mr. MACGIBBON commences with Vienne, near Lyons. It is a long way from the coast, but it suggests the extent of the Roman works. Very little is added to the information which "Murray's Guide" furnished long ago, about the temple and the Forum in the town and "the Needle" outside. Indeed, Mr. MACGIBBON would have made a better book if he trusted everywhere to his own observation. But the illustrations are suggestive. The next town is Orange, which bears evidence of Roman occupation in the theatre, with its mighty proscenium, and the triumphal arch. The proscenium is not only a solitary survival, but it differs from those which are introduced in representations of the Roman theatres. The wall is 335 feet long, 112 feet high, and 13 feet thick. Behind it are enclosures, which may have formed dressing-rooms, but a century ago they were used as prison cells. What is most remarkable is the shallowness of the space which was reserved for the performers. If we assume the clear opening to be about 220 feet, the depth could hardly exceed in any place 40 feet. There was accordingly a great limitation in means to produce effect, but on the other hand spectators had always a splendid piece of architecture adorned with sculpture before their eyes instead of painted canvas.

As it is not narrated in "Murray," Mr. MACGIBBON does not appear to be acquainted with the history of the restoration of the triumphal arch, which is interesting for several reasons. In the thirteenth century a donjon was erected upon the Roman arch by RAYMOND DE BAUX, and it was allowed to remain until 1721. After it was demolished the stones were cast in a heap beside the arch, for which they served as a sort of buttress. The arch needed support of that kind. Occasionally something was done to keep the masonry together, and a timber roof was placed over the structure, but the repairs were entrusted to the masons and carpenters of the district. In the beginning of the present century the arch was in imminent danger of falling, owing to the removal of the stones which belonged to the donjon. But no steps were taken for the preservation of the arch until 1825, when M. CARISTIE, the architect, was sent from Paris to restore it. His first endeavour was to make the structure solid, and next to conserve everything ancient that could be utilised. He found it necessary to remove masonry, but he took care that what was substituted should never deceive a spectator. Mr. RUSKIN speaks admiringly of the sketchy character of the reliefs, but it was the aim of M. CARISTIE to impart to all the new work "un caractère d'ébauche," in order that any chance of confounding modern with ancient work might be obviated. The architect was able to find the quarry of Baumes-de-Transit, from whence the original builders drew the stone for the arch; but, although it offered a temptation to imitate the detail that was removed, M. CARISTIE practised no deception. In cornices he avoided mouldings, and where a part of a column is restored he omitted the fluting.

When the arch was erected and for what purpose are not revealed. M. CARISTIE came to the conclusion that the Arch of Orange, with others in the district, especially those at Saint-Remy and Carpentras, were alike in ornamentation and sculpture, and therefore were erected about the same time. He considered they were intended to celebrate the victories of MARCUS AURELIUS. His opinion was adopted by PROSPER MERIMÉE, on whom Mr. MACGIBBON depends. We hope, in his next edition, he will recognise that any credit which comes from the theory belongs to M. CARISTIE. Another theory, which M. LENORMANT worked out with great skill, is that the arch was erected to commemorate victories over JULIUS SACROVIR, the Gaulish chief, who was defeated near Autun. There is the word "Sacrovir" still surviving on one of the trophies as evidence to support it, and that is almost enough to give rise to a theory, but the general design of the Orange arch is supposed to be of a period at least a century later than the defeat of SACROVIR, which occurred in A.D. 21.

MERIMÉE was also indebted to M. CARISTIE for the information which Mr. MACGIBBON retails about the construction of the upper part of the theatre at Orange, and other details which would not strike an amateur. One can hardly

\* *Architecture of Provence and the Riviera.* By David Macgibbon. Edinburgh: David Douglas.

fancy the author of "Colomba" climbing ladders 112 feet high in order to discover what kind of covering was employed. MERIMÉE was a most useful director of the Historic Monuments Commission, but it is time to cease taking him at his own estimation as an archaeologist.

Arles has still two storeys around the enclosure of its amphitheatre, and the benches are in part preserved. The theatre, which, if not so large, was a finer piece of architecture, has to be judged by a couple of columns. At Nîmes the amphitheatre can be also used. The corridors are roofed by massive lintels of stone, which in many cases are cracked, and the cause is generally supposed to be an earthquake or a conflagration. Mr. MACGIBBON ascribes the cracking to the vicious form of construction, which could not sustain the superincumbent weight. In describing the Maison Carrée, he adheres to stereotyped statements about irregularities, and it is satisfactory to find that the author has the courage to say that, "Notwithstanding these defects, the Maison Carrée is a building of which Nîmes and France may be proud;" words which will, we suppose, persuade Frenchmen to keep the building from destruction.

In treating of Christian architecture, Mr. MACGIBBON substitutes for the statements in "Murray" a theory which is due to Professor BALDWIN BROWN, and derived from DE ROSSI. According to it, the model of the early Christian church was "the scholæ or halls of meeting of private societies." With the aid of the light afforded by this supposition, the course of church architecture is traced through Roman and Byzantine times. The influence of Venetian traders is introduced as a factor in French architecture, and it is suggested that St. Front Perigueux was borrowed from St. Mark's but constructed by a native artist. The following extract will suggest Mr. MACGIBBON's argument about the peculiarities of the buildings in Provence, and also how well the author can state a case when he trusts to himself:—

At a distance from Perigueux, as a centre, domes are sometimes used, as is the case, for instance, in Auvergne; but in Provence the dome is generally limited to the space over the crossing. In the latter locality the Byzantine influence exhibits itself in a different direction, being chiefly confined to details and subordinate features. But here another factor comes into play. The presence of the Roman monuments still existing in Provence has evidently tended to impress a Roman character on the architecture of the district. So strikingly indeed does some of the Provençal architecture resemble Roman work, both in general design and in detail, that it has frequently been maintained that it is actually the work of the Lower Empire. The style of Provence in the twelfth century differs on this account considerably from that of the other Romanesque styles. The revival which took place all over Europe in the eleventh and twelfth centuries occurred in Florence also, but the result there was somewhat peculiar, the effect of the Roman remains being to produce in many of the features of Provençal architecture a closer resemblance to the Romanesque style of Rome and Italy than to that of the Rhineland and the North. The towers and campaniles of Provence also either correspond in design with those of Italy or are imitated from Roman monuments in the country. The circular baptisteries, of which a good many examples survive, are, like those in Rome, constructed with columns and caps from ancient buildings, or are wrought in imitation of them. Sculpture also abounds in Provence, being inspired by the abundant remains of ancient work in the favoured provinces of the Empire.

(To be continued.)

## ARCHITECTURE AT THE ART CONGRESS.

MR. BASIL CHAMPNEYS read a paper entitled "Style." The development of style had, he said, been gradual and harmonious, and its practice had been the result neither of theory nor argument. But in the present day the architect found himself unaided by any prevailing taste or tendency. The best means of remedying this state of things and for bringing architects generally to some common aim would be to arrive at certain wholesome limitations. He advocated architects limiting as far as possible their study to English work, which must necessarily have more fascination for Englishmen than foreign work, and which was certainly as good if not as magnificent as anything to be found on the Continent. In all cases they should prefer purity of style to mere extravagance, and never consciously aim at originality.

### Obstacles to Progress.

Mr. T. G. Jackson read a paper on the subject of "Obstacles Opposed to the Progress of Architecture by Architects Themselves." He said that, considering the importance of good architecture, it was astonishing to find

such general indifference among the public. The remedy was in the hands of the architects themselves, who were by no means working in such a way as to put their best before the public. Like other works of art, architecture was only good so long as it bore the stamp of the artist's personality, and the only architect deserving that name was the man who attended to the smallest detail of his design and work. Unfortunately nine-tenths of our buildings were not so attended to. The majority of those who were themselves architects gave the greater part of their time to work more properly belonging to the surveyor, the lawyer, or to the commission agent, and only the leavings of their time to architecture. Their own actual work was accomplished with the aid of "ghosts." The architects should most certainly stick to their own craft, because they would find in it more than enough to occupy all their time and energies, and because unless they devoted themselves to it entirely they would never hope to do good work.

### Coloured Decoration of Churches.

Mr. E. Prioleau Warren in his paper pointed out the backwardness in decorative art of the ecclesiastical branch as compared with the civil and domestic, and said that in the decorative school of the fifteenth century, the work of which was exemplified in many of our churches, they had ample suggestions for modern use. A protest was entered by the speaker against the neglect of the use of colour in churches, and the impression prevalent among architects that the decoration of churches was a matter beyond their scope, and therefore to be relegated to specialists. He expressed the opinion that architects should carefully study colour effects, should design their buildings with the view of receiving the colours, and should be their own decorators.

### Architecture and Liberal Education.

Professor Roger Smith explained the gradually-increasing scope and aims of modern education and culture, and said that, as they had come to the study of art, they should certainly include in an art education the study of architecture. Education contemplated general training and cultivation, together with specific preparation for after life, and if from art they omitted architecture one-third of the subject disappeared. Architecture could perhaps better supply the kind of training required than any other of the fine arts. It more than any other art rested on abstract principles. It was closely allied to science; it was historic; it fitted a traveller for understanding what he saw, and it added a new interest to archaeological studies, &c. There were few things which would better aid a man in fitting himself for public life than a proper and careful study of architecture.

### Nature of Architectural Ornament.

Mr. H. H. Statham afterwards read a paper explaining that all natural ornaments when used in architecture required to be conventionalised or treated in a special way. There were, he said, ample resources in nature for decorative purposes, and there were many forms in nature which had never been used, although they might well be so treated. He did not make this assertion without proving that he was correct in what he said, and for this reason he had come prepared to illustrate his paper with lithographic sketches and examples of casts.

### The Outcome of the Congress.

Mr. H. Sumners in his paper said that there could be no doubt as to the wonderfully elevating and beneficial effect that the words and work of the congress was certain to leave behind, and which would permeate not only the city of Liverpool, but the nation at large. Throughout all they must have been impressed with the singular unanimity of opinion upon the great want of appreciation and encouragement of art, and with the great divergence of opinion as to the correct mode of educating those by whose handicrafts the designs of the masters in art were carried into execution. It must be admitted that there was in our midst, and in the ranks of the artisans, capability to do good work; and one powerful means of getting good work was to give the artisan an incentive to work and to make him less of a machine. A very desirable result of that congress—in fact, the one great result to be desired—was the establishment and encouragement of trades technical schools. In Liverpool there were no such schools, although they had science and art classes, Government schools of art, and classes at University College, at which, however, he was afraid, few artisans attended. He believed that the several trades organisations were grasping the situation, and were about to encourage the formation of, and fill with pupils, technical schools of their own, so as to entitle themselves to a share of the grants from the public funds set apart for that purpose. This school or institute was to offer to the artisans and apprentices to a trade an opportunity of studying the branches of education particularly bearing upon their respective trades. With this object in view, a provisional committee had already entered into communication with the

Government Science and Art Department and the City and Guilds of London Institute. It was necessary that local pecuniary aid should be given to push on the scheme in order to obtain these grants, and for the obtaining of this assistance an appeal was shortly to be made to the city council and to others interested in the movement. With such a school the younger artisans would gain in their youth the life-long acquirements and dexterous modes of skill attained by the elder handicraftsmen, and thus the nation would benefit. Thus they would proceed until they arrived at a state of working that might in interest and organisation become a "trades guild," in which the members from apprenticeship upward would be necessarily instructed and made efficient in their particular crafts. It would follow that there would be no "duffers" or "drones" earning under false pretences the wages of the true handicraftsman. The organised trades of Liverpool were determined to form such a school, and they believed that there were gentlemen of position, means, and influence who would take this great measure to heart, and come to their aid in a liberal and generous manner.

### SCULPTURE AT THE ART CONGRESS.

A PAPER was read by Mr. W. Emerson on "The Decoration of Public Places and Buildings." He remarked that in England our public works did not tell any tale of our religious, historical, or domestic lives, unless perhaps it be, by the conspicuous absence of sculptured history, that the nation as a rule was so given up to trade, commerce, and money getting that there was interest for little else besides. The provincial towns, though Liverpool had some sculpture in connection with its St. George's Hall, were equally with the metropolis deficient in historical incident represented by figure subjects. Why, he asked, was this marked absence of illustrative sculpture in connection with our national buildings? Had England no history to be proud of, no foreign relationships, no India, no Colonies? Had we no wars by sea or land, no interest of peace, no State trials, no scientific discoveries, no trades or specialties of commerce, no amusements or pursuits in our domestic life, and no literary works worth illustrating? And, lastly, had we so little religion that we were ashamed to render in stone, marble, or metal subjects illustrative of our belief? In all countries and times religion had been the foster-mother of sculpture in connection with architecture; political power and wealth its nurses. He urged upon the State the duty of insisting that our public buildings and places should be more instructive in their character; or what use was it, he asked, to institute academies and schools of art all over the country, and to encourage men to turn their attention in the direction of art, and to educate numerous art workmen, if there was to be no outlet for their future efforts and abilities?

Mr. Bruce Joy alluded to the sculptural work of St. George's Hall. He remarked that Mr. Sterling Lee's panels were most beautiful work, and a real adornment not only to the hall but to Liverpool. That, he added, was the unanimous verdict of all who had seen the work.

Mr. Tarver said we should have more sculpture in England when we could enjoy it sympathetically and saw people of our own time represented—and the people of our own time would be represented when our costume was representable. He hoped to see our costume so modified as to be sculptural, and for that they must look to the great people, such as the Prince of Wales, to set the fashion.

#### Influence of Sculpture on Painting.

A paper was read by Mr. J. B. Gibbs with the object of showing that painting, in all its branches, was perhaps more influenced by sculpture than any other of the fine arts. He deduced examples of this fact from the histories of the famous painters of the Roman, Florentine, Venetian, and Spanish schools. In the paintings of the Dutch and Flemish schools this influence of the antique sculptures was not seen to any great degree, and with regard to the painters of France the influence was varied and uncertain. As to the painters of our own country, it was well-known that the antique had been studied and its spirit absorbed by great artists who had passed away and by many who were at present in existence. Landscape perhaps was the art of this country which was least influenced by any study of the figure; that was to say, that many landscape-artists had not considered it necessary to draw from the antique and nude until within the last few years. But the value of the principles by which the work of the ancients was produced was just as great to the art of landscape-painting as to that of the figure. To work after the manner of the great masters of the past ages—to work in the spirit which was the very soul of great and high-minded sculpture—was not to copy the outward forms of the antique, make men like statues, paint only classical subjects, but was rather to express correctly in painting the character to be represented, and this in a firm,

intelligent manner, taking care to avoid introducing detail which would draw away the attention of the beholder and lead him to praise the artist's mechanical dexterity, instead of the way in which the intellectual part of the work had been accomplished. To give full effect to this intention a thorough knowledge of drawing and colouring was necessary, and it was to be obtained by careful training and drawing from the antique and life. He would be very glad to see in our schools of art casts of modern sculptures, for by that means the interest in modern sculpture would be increased among the numerous art students, and would spread to the world outside. It would also induce a more healthy critical spirit, while the presence of such works by living artists would act as an incentive in the struggle towards the nobler spheres of every kind of art. He wished that all the Dutch painters had struggled to represent in their works the ideal which was expressed in the antique.

The President entered his protest against the tendency to put everything that was bad down to the Academy. He had no more generosity shown him anywhere than in the Academy School. They were not taught to do any special thing there; they were directed.

#### Architectural Carving.

Mr. Samuel Fry discussed the conditions desirable for the carver and the nature of his work. The carver's aim must be subordinate to the design of the building of which he had to emphasise and beautify the chief features. In the useful arts—of which architecture stood at the head—there should be economy of material and grace of form, a blending of construction and beauty, that the result might be a beautiful economical structure. In some useful arts the scientific element could less readily give way than in others to the spurious artistic. But in dressing, he asked, what could be more execrable than disfiguring and injuring themselves for the sake of fashion? A little more utility here would produce more comfort, and turn ugliness to beauty. Unless the æsthetic and practical were both fully represented in useful art it was no true art.

#### Art Metalwork.

Professor W. C. Roberts-Austen, F.R.S., read a paper "On Certain Applications of Gold and Silver in Art Metalwork." The paper was written at the request of the President with a view to indicate certain directions in which the precious metals might be used in art metalwork; the subject being treated from the purely metallurgical and technical side, and pleaded for the widely extended application of coloured metals and alloys in art.

#### Enlarging the Field of Sculpture.

Mr. Alfred Gilbert, A.R.A., in his presidential address, said he was convinced that the time had come for sculptors to devote their efforts to the service of the art in a broader and more liberal spirit than had heretofore been in vogue. This duty was imposed upon them by the increasing demand for their co-operation of the great architectural revival now making itself so evident in our new streets and dwellings. Formerly artists lived to work; to-day they worked to live. One lesson we learned from the work of the past age was that not one of the beautiful works belonging to it had been created without a purpose, and in every case the purpose had been one of use as well as beauty. The ready market for Japanese curios and all sorts of objects *de vertu* should be sufficient encouragement for the production of such wares. The introduction into our modern houses of all the luxuries in the way of ornamentation—ornamental ceilings, coloured tiles, carved wood, metal fittings, and a host of other artistic luxuries—offered an enormous scope that should be sufficient to warrant more special attention and study in the direction of meeting those requirements. But he was bound to admit that the encouragement to seize these suggestions was small at present, as the majority of the rich public were in the condition of being obliged to purchase taste as well as wares through the medium of the professional middleman. He hoped the congress would have a beneficial effect, if it did no more than bring about a frequent intercourse and exchange of opinion between artists themselves, and between them and the outside world. Mr. Gilbert afterwards referred, with emotion, to the case of Mr. Sterling Lee, the sculptor who was employed to decorate the panels outside St. George's Hall. He said it was eminently unfair that the artist—to whom this work of providing a series of panels for the decoration of the hall was entrusted after fair competition by a committee who knew what they were about—should not only be denied the right to complete his scheme and express his meaning to the end, but have to bear the double humiliation of seeing his work unfinished and his powers questioned. He (Mr. Gilbert) was not there to crave their pity, but their sympathy, and to ask them to extend that generosity and liberality they had shown to the artists present to an absent brother artist, who—it pained him to say it—was too broken and discouraged, even were he not, like a true artist, too proud to beg for himself. It was not for him (Mr. Gilbert) to vouch-

safe his personal opinion, unasked, of the work, although no doubt a fairly clear idea of what it was would have struck them; but he asked that a committee of competent artists, composed of sculptors, painters, and architects, be formed, before it was too late, to settle this painful question, and the good name which Liverpool this week had justly earned by inaugurating a movement like this should no longer be so stained as to qualify its right to the distinction.

Mr. Damer Harrison asked the chairman whether it was not competent for that meeting to pass a recommendation to the municipality of Liverpool with regard to Mr. Sterling Lee's work. After the powerful appeal made by Mr. Gilbert, he did not think they ought to leave that room until some practical effect had been given to Mr. Gilbert's suggestion. He moved the following resolution:—"That this meeting recommend to the consideration of the Liverpool City Council the appointment of a committee, constituted of sculptors, painters, and architects, to determine upon the merits of the work and designs of Mr. Sterling Lee for the decoration of St. George's Hall, and to advise the Council upon the matter, so that justice may be done."

Mr. George Clausen seconded the motion, which was carried with one dissentient.

### APPLIED ART AT THE ART CONGRESS.

THE subject of Mr. Walter Crane's presidential address was "The Advancement of Art and its Application to Industry." He said they were met to further the advancement of art in its application to industry, but were they sure they did not mean the advancement of industry by the application of art? For centuries past everything had been done to forward profit-making, and the result was that art could hardly find a place for the sole of her foot. Mechanical invention in the interests of trade had dominated us, and mechanical invention had outstripped the invention of the artist. Mechanical smoothness had taken the place of artistic thought and finish, simply because the amount of output was more regarded than the artistic quality of the material and work. The whole structure of applied art was built upon the shifting sands of insincerity and speculation. Art and industry should be inseparable, but the spirit of industry was merely to produce, that of the artist to express also. Commerce, like the old woman in the nursery tale, stood at the stile of an overstocked market with her obdurate pig, over-production, which refused to move until the stick of new demand had been brought to use its influence; and so all the characters of the commercial drama acted and reacted, even so far as the ox—possibly John Bull—driven to action by the goad of the butcher, the Nemesis of foreign competition. Meanwhile the fluctuating harlequin of fashion and trade came and went; this year we were going in for being artistic—everything was to be artistic—art colours, art furniture, art in the attic, and art in the coalhole. Next year, away with your degraded colours! Let us be grandly barbaric in mauve and magenta! And so art and industry remained an ill-assorted couple, furnishing an additional modern instance to point the moral of those who asked "Is marriage a failure?" To those who delighted in personal work and characteristic, the employment of steam as a means of reproducing art was a mistake. The system of production was not economically organised in the interests of the community, but rather for the profit of individuals. In handing art, as a commodity, over to the insensate machinery, both its spiritual and sensuous delights vanished, and the refining and educating influence of its practice and its ultimate appeal were lost. The demands of the public were such as to cause the designer to evolve something that was new, and that novelty was taken as its sole and entire merit. Producing art by machinery was like misquoting a poet on a hundred pages and calling it a book. In the means of producing art by machinery we had lost sight of the end in the means. The purely artistic production, the old methods and old tools, remained as they were, for the simple reason that nothing could supersede the hand. That personal touch valued so highly in the fine arts had practically disappeared from the handicrafts, although with the enormous existing power of reproduction it was absolutely important that the designs should be good. In this country the term "artist" had come to mean only the pictorial artist, to whom fortune, fame, and favour were open almost exclusively. This he ascribed to the Royal Academy, which was supposed to foster the arts, but really fostered the one art only. Every man who had risen in the art world had really done so against the influence of the Academy; but directly he entered the charmed circle his individuality was swallowed up. The fact that local exhibitions were under the influence of the Academy also contributed to the present condition of art. Many of the art schools were rendered useless by the desire of the managers to pass as many students as possible through a certain number of standards. If we really had the honest desire to unite art with

industry, they should see that the craftsman had personally the credit of his work as well as the responsibility. Art industry seemed to be the Cinderella of the arts. They must endeavour to turn craftsmen into artists and artists into craftsmen, for that was the problem before them. Exhibitions of arts and crafts were very useful in forwarding the work, as were also the guilds of arts and crafts. But do not let them deceive themselves, or expect to gather the grapes of artistic or industrial prosperity from economic thorns or æsthetic figs from commercial thistles. Let them each contribute their quota of influence to the tide, and the question would be solved.

Mr. P. H. Rathbone said he must deny the accusation that the Liverpool Art Gallery was under the domination of the Royal Academy. They were most anxious to give any good artist a fair chance, as the walls of the gallery would show.

### Art and its Producers.

Mr. William Morris in his paper offered the following proposition:—"Whereas labour is usually assumed to be the necessity of earning a livelihood; and whereas, in their modern society, this was really the only incentive amongst those of the working classes who produce wares of which some form of art was supposed to form a part, it was impossible that men working in this manner could produce genuine works of art, therefore it was desirable either that all pretence to art should be abandoned altogether, and that arts should be restricted to matters which have no other function to perform except their existence as works of art, or else that to the incentive of necessity to labour could be added the incentive of pleasure and interest in the work." Should they, he asked, pretend to produce architecture and the architectural arts without having the reality of them? Should they give them up in carelessness or despair of having the real, or should they set themselves to have a reality? He was in favour of adopting the third course, and he urged it upon his hearers. He addressed himself to showing that the architectural or ornamental arts formed an integral part of the consciousness of manly life. This was his theory under which genuine architectural arts could be produced, and it was founded on the view of a historical development of that industry. The present system of production, he argued, had turned a handicraftsman into a machine; and he urged that the system of production must be changed; machines should be made their slaves and not their masters, and the whole system of society should be recast.

### Municipal Art Section.

Mr. Edwin Seward read a paper on "The Development of Local Influences for the Advancement of Art." He advocated the formation of a purely working artisans' section, connected in some way with the grant system of the Science and Art Department, and the establishment of some sort of scheme for recreative education, which the department might step in to aid later on. In helping that kind of work, local art associations could accomplish much, and where possible, ought to be of two kinds, one for amateurs and others of that class who already liked art well enough, but who, for want of well-directed influences, were of small use to art itself, and the other consisting of organisations for the training and practice of artisans, both being distinctly in touch and working together in such matters as periodical exhibitions. It would be easy in most towns to bring about the establishment of committees for recreative education in connection with the corporation or the governing body, and by that and other means the artisan and his son or daughter could gradually be led forward towards art, and thus the ground could be prepared for that higher training which art and technical schools, colleges, museums, picture galleries, and art societies could impart.

Mr. P. H. Rathbone, speaking of the love of art among the working classes, said that the difficulties in connection with the art exhibitions in Liverpool had not arisen with the people. It had been the upper middle classes who had chiefly been deficient in their encouragement and appreciation of art, for although they might fill their drawing-rooms with pictures, that was not national art and the people's art.

### A Plea for Decoration.

Mr. W. E. Britten read a paper in which he said that the people would have ornament, be it ever so crude, and artists still hoped to have their Minister of Art who would exercise his influence in taste as to necessities. Artists felt the want of a modern Pericles in the Cabinet to set out on a new artistic campaign, and at the bidding of really capable men undertake large plans and schemes for the adornment of long black and dingy streets in colourless London. The Renaissance of red brick was very welcome. They should seek a royal charter for the support of the Association.

### Things amiss with Art and Industry.

Mr. J. D. Sedding read a paper. He said they were told that machinery was really the cause of the wrong-going of art and industry, that it disturbed the contact and the sympathy

between the manufacturer and the operative. But there was some things much more to blame than the machine, and those were the bad designs of the manufacturer. Our industries were undoubtedly suffering from bad design, bad material, and the miserable life which was lived by the operative. All the art schools, lectures, and even congresses in the world would not avail unless they surrounded the artisan with comfort and some degree of happiness. The only remedy which would meet the case was the application of Christianity in a Christ-like way; but the modern Englishman preferred to work by means of Act of Parliament, and perhaps the Act of Parliament which might remedy the evil might come in a measure for profit-sharing and for giving the workman the interest and profit of his own work.

Professor Aitchison said he did not think art could be promoted by Act of Parliament. They must try and educate the people to a thorough love of art, and when there came a general demand from the people it would be acceded to.

Mr. William Morris said that Mr. Sedding was inclined to deprecate the use of museums in regard to the study of the arts. It was rather a difficult point to decide. He was inclined to agree with much that had been said by Mr. Sedding; at the same time the museums preserved for them the traditions of style and art to a great extent. He desired to protest against the line drawn between the intellectual and the non-intellectual—if there was such a thing—in art. Supposing they wanted to raise a school of decorative art and desired to have workmen who would be able to express their feelings and ideas through the medium of decorative art, they were met by this difficulty, that workmen who expressed themselves in that way were still only workmen, and they would undoubtedly, if they had anything in them, strive to do their utmost for their own material advantage in the world. The result would be that they would rise, if they called it rising, out of the working-man class and become those gentlemen artists of whom he spoke on the previous day. As long as that went on they would be foiled in their endeavours to get a large mass of capable workmanship amongst the people in whom they desired to see it.

Mr. E. R. Russell, who followed, said they all admired Mr. Morris's ideals, but there might be a danger in admiring them that they would lose the practical means which might lead them furthest towards their accomplishment. He shared Mr. Morris's regret that many workmen did art work without rising out of their position as workmen, but on the other hand it was utterly Utopian to suppose that everybody concerned, say on a building, could have an equal degree of artistic feeling in his work, and to this they could never hope to attain. What they might hope for was that each person in his degree might be enabled to secure his rights as a man and as a workman. For instance, a stonemason was entitled by combination with his fellows, and by "striking" if necessary, to secure proper wages and a proper amount of leisure. The artist workmen, on the other hand, had to take similar precautions in order to get their names connected with their work. If that were done they might depend upon it that Messrs. Doulton's workmen, for example, would very soon be raised from the position of mere workmen by the recognition which the public would give to their work.

#### Craft Ideals.

Mr. T. J. Cobden Saunderson read a paper describing the bookbinder's craft. After a description of the conditions under which the craft was at present carried on, Mr. Saunderson spoke of the supreme aim of bookbinding, which he declared to be an art as well as a craft. He said that this supreme aim was an act of homage to the genius of a writer. A binder must be an educated as well as a skilled man, and he should strive to have his binding looked upon as the temple of the great spirit enclosed within it. This declaration as an act of homage was impossible unless the binder himself was a literary man and had been inspired by admiration for the book and its author. If the creation of beauty and strict utilities was made a domestic, a civil, a national and an international object, then every craft and art alike, issuing from the true fountal source directed to great ends, and converging to one result, would have its own significance, would be co-operative, would attract to its practice every variety of talent, would be followed with enthusiasm, and would be its own exceeding great reward. But to effect this the "educated classes" must be educated, and for the gigantic incubus of modern commercialism must be substituted a socially organised method of life having beauty for its aim. The "educated classes" must be made to long for and to work for this transfiguration of industrialism into a "thing of beauty."

#### Fashion and Manufacture.

Mr. Lewis F. Day said it seemed that fashion was dead against art, and he questioned whether they were compelled to follow fashion simply because it was fashion, or whether fashion was for the general good. Even for manufacturing enterprise there could be no more insecure basis. But the

manufacturer really considered himself, not the public, and he sought to create new wants rather than to meet those existing. Purloining patterns was too common, and the only antidote to piracy was honesty, not fashion. Mr. Day deprecated the habit of the artist being kept subservient and unknown, and the benefit of his work being entirely reaped by the manufacturers, who kept him unknown and underpaid.

#### Decoration in Plaster.

Mr. G. T. Robinson, F.S.A., read a paper upon "Sgraffito and other Processes of Decoration in Plaster," the address being supplemented by the exhibition of a number of illustrative specimens.

#### Sculpture, Architecture, and Applied Art.

Mr. John Belcher's paper treated of the necessity for architecture and sculpture being in intimate and affectionate relationship. A certain self-assertion and exclusiveness on the part of sculpture had been prejudicial to her best interests, for when one art not only jealously disregarded but even endeavoured to exclude another, it was to her decided loss, and the effect was injurious to both. On the other hand, architecture had too often given offence by her utter disregard of the functions and requirements of sculpture; for example, by placing figures and groups here, there, and everywhere to fulfil ignominious duties. Both architects and sculptors might meet each other half-way without fear in the development of figure friezes and panels in low relief, and find the field enlarged as public interest and sympathy were aroused. The architect, he said, must lead, indicating clearly the sculptural treatment to which the sculptor was to give expression. The sculptor could give point to a design by concentrating the attention in a dominant motive, and it was by his aid that many effects of grandeur and largeness of scale were obtained.

#### Sculpture in its Relation to Architecture.

Mr. George Simonds, in his paper on this subject, remarked that many of our public buildings were left so unadorned as to give one the impression that they were stopped for want of funds. It was the same with private building, which was usually the work of speculators, who were the curse of art and artists. Such builders spent nothing on adornment that was not of the least costly and most showy order. The present claims of the English to be considered as an artistic people were founded chiefly on the excellence of the pictures which year by year were produced with unwearied energy by an ever-increasing army of painters; for a walk through our cities would convince any one that our efforts in the direction of monumental art were rarely as successful in the present day as they were when England was comparatively a poor country, sparsely populated, frequently convulsed with war, and unblest by the resources of modern civilisation. One great reason was the apathy of the public to all art that was not portable property. Another reason was to be found in the feverish impatience and inconsiderate haste with which modern works were pushed forward to completion. Again, the commercial desire to get the utmost work for the least pay had not a little to do with it; and last, but not least, a serious defect lay in the education of our artists. The Government funds expended in the education of artists were spent not wisely nor too well. There was no need for forcing houses for artists, nor for the creation of a supply where there was no demand. If the nation spent more on the decoration of public places and buildings, and less on the artificial incubation of artists, he thought the result would be that they would have something to show for money so spent, and that the demand for artists would stimulate the supply for a more satisfactory article. He condemned as highly injurious the constant teaching of the doctrine that art was divided into painting, sculpture and architecture, saying that it should be boldly proclaimed that the union of architecture, sculpture and painting alone was art. Divided, they were lovely but helpless branches; united, they formed that noble tree, art itself. If they might judge of the future by the past, they might expect the attainment of the highest results by giving to our artists such an education as they obtained in the fourteenth and fifteenth centuries, before the Government schools of art and other kindred institutions propagated artists, like mushrooms, artificially. The sculptor, the architect, and the painter would each certainly be the better for the broader education he advocated.

#### The Relation of Architecture to its Constituent Arts.

Mr. W. A. S. Benson in his paper maintained that the position of the modern architect was in some respects analogous to that of a conductor of an orchestra or the stage manager of a theatre; he did not execute the work, but he directed and controlled the actual executants. There were two conceivable extremes between which the ideal as well as any actual practice must lie. At one pole was the theory of the omniscient architect directing absolutely mechanical operations; at the other, the theory of a fortuitous concurrence of equal and harmonious craftsmen. Of course, neither extreme had ever been

practised in its full completeness; but while they were not at present likely to be troubled with any approach to the latter condition, there had run through a majority of the papers read at the congress a note of protest against the approximate towards the despotic pole of architecture which has persisted. The result was seen in the fact that architecture was no longer co-extensive with building, it being a liberal estimate which would credit anything that could be called architecture with one-tenth of the building of the day. The evil was flagrant, and admitted by all who had ever regarded the subject. There were those who proposed to correct the evil by a compulsory examination and registration of architects under an Act of Parliament, no doubt to be followed in logical sequence by a Bill for the compulsory employment of such registered architects in all cases of buildings. This was the autocratic ideal, the use of the strong hand. Whatever this proposal might do for the business of architecture, it would by no means benefit the art. He held it to be the distinctive and abiding function of an architect to determine the order in which the various co-operating arts and crafts were to contribute to the building, and to fix the scale and proportion of the several parts and of the whole. It was no part of the ordinary work of an architect as such to originate new structural forms, or to design anything which he could protect under the patent and registration laws. So far from constituting architects a caste of themselves, he would have them simply the leading members of the combined building crafts. Sculptors would head a goodly fraternity of carvers and modellers of every sort. With regard to painters, he did not think art or artists would be in any way the losers if there were some middle term between the art student and the full-blown painter of cabinet pictures in oil.

Mr. Statham condemned the idea that every building must have ornamentation upon it simply for the sake of the ornament apart from suitability.

Mr. G. H. Garraway said every man seemed to set up for himself and his cashbox. Referring to Government patronage, he said artists should be more independent than to seek such aid.

Mr. Edmund Kirby said he doubted whether the public were so apathetic as Mr. Simonds seemed to think. He thought the public appreciated sculpture more than painting. There was so great a difficulty in getting sculptors to execute architectural sculpture that he had to send to Munich to get his own designs carried out. And he knew many other architects who had to adopt a similar course.

Mr. Simonds said architects expected sculptors, who had spent their lives in learning their profession, to work at the same rate as stone-carvers, who had not so spent their lives.

#### The Teaching of Industrial Art.

Sir Philip Magnus read a paper, in which he said that every art had a technique of its own. In his endeavours to add the beautiful to industrial manufactures the artist was met with the limitations of—(1) the use to which the things were to be put; (2) the materials in which they were made; and (3) the appliances by which they were made. The history of the German industrial schools was then commented upon, and a sketch of the French schools was also given, and the reader stated that almost all the English manufacturers received their designs from these countries. He would advocate the teaching of drawing to all children, and from them the best would be found capable of further artistic education. In spite of all that had been said at the congress, machinery would go on developing; but he would like to know if the artists could tell the manufacturers how their goods were to be made more beautiful and how art was to be more intimately allied. It was by the artistic training of artisans that industrial artists would be made. Trade museums would also be a good means of instruction, but they would never be fully useful until artisans were permitted to visit them at such times as they had leisure to observe and rest to think upon what they saw. The connection between the excellence of French designing in special branches and the general system of art education in France was not difficult to trace. The teaching of drawing in that country was almost universal, and exceptional facilities were afforded to artisans of all crafts to acquire art knowledge and artistic skill by means of trade museums. As a contrast to this, the British art schools were not much utilised by artisans, perhaps because few of them had learned the primary principles of drawing. And many of the schools were very imperfectly supplied with the necessary appliances for good art teaching. In Paris the schools were crowded nightly with artisan students drawing and painting from the living figure, both nude and draped. It was a matter of the greatest importance to determine the best means of obtaining successful designers and artistic craftsmen, for upon the adequate supply of these depended to a great extent our ability to compete on equal terms with our Continental neighbours.

Professor Hele Shaw said the moral to be drawn from Sir Philip's paper was that they must get at every unit of the population, and have some means of selecting the fittest instead

of selecting haphazard the art students. Liverpool was not behindhand in the work of technical education. He alluded to the work of the Home Arts Association, of which Miss Calder was one of the founders; and of the Association for Technical Education. The latter body had a scheme of work. Believing that some manual instruction should be given to children, they had divided the schools of the city into centres, and had arranged for instructing 500 boys each week in fret-saw work and wood-carving. They were also organising assistance for this instruction. Through the aid of trades unions and other organisations, they were arranging that apprentices should be encouraged to do work, and attend special classes, to be called "apprentices' classes," in distinction to amateur classes, and their work would be exhibited in the spring of next year. One feature of the scheme was the instruction of primary teachers. Eighty-three head and assistant masters of public elementary schools had certified their willingness to work after school hours at the Engineering Laboratory. Accommodation had been made there for seventy, and these were now at work; and they in their turn would give manual instruction in the schools. With regard to the boys, he might say there were no fewer than 1,100 applications for instruction in this work. That showed that in Liverpool there was a desire for instruction, and the Association was started to carry on what was essentially a voluntary work.

#### MUNICIPAL SECTION OF THE ART CONGRESS.

A PAPER was read by Professor Baldwin Brown on "Mural Painting." He said that in general estimation it was the cabinet picture that was the typical work of the painter's craft; but if we examined the history of painting we would find this had not been the case. In Italy, the chosen home of the painter's art, the works that were visited were mural works. We ought not to be indifferent to the improvement of our national art from the comparative absence from it of mural painting, nor ought a revival of it to present any great difficulties. A noble example had recently been set in Manchester in the employment of Mr. Ford Madox Brown to fill the panels of the town-hall in that city. The difference between the cabinet picture and the decorative painting on the wall was explained, and it was shown that the painter who turned from the easel to the wall must sacrifice something; yet he was a gainer to a large extent in return. Instead of working as a private artist of a private patron, he would have the sympathy and the applause of the whole community, and his work would be invested with the warmth and common sentiment which attached to national or civic undertakings. He must abandon searching into detail, and must simplify his painting, but he would gain in return in elevation of style. Of this elevation of style the works of the great Italian frescoists were the best example. Further, it must be left to the painter to choose his own subject. Professor Brown suggested that the Science and Art Department should be asked to publish a handbook on the technical process of mural painting, materials for which book were already in existence in blue-books and elsewhere. We also wanted the chemist's aid with reference to the permanence of materials used in wall-painting.

Mr. P. H. Rathbone said that if opportunities were afforded, artists were ready to undertake fresco-painting, and pointed out that it was a humiliating fact that some years ago the London and North-Western Railway Company refused the offer of Mr. G. F. Watts to paint the great hall of their London station, free of charge except for the material. A similar thing happened in the case of Mr. Richmond, who offered, for a sum which would not cover his expenses, to paint the interior of the Liverpool Council Chamber with the design of "Commerce Overcoming Barbarism."

Mr. A. Harris said the chief argument against mural painting was as to its performance, and, therefore, they could not expect municipalities to rush into what seemed a doubtful experience. What was wanted was an inquiry into the technicalities of fresco-painting, and with that object in view he moved, "That this congress approach the Science and Art Department with a view to their consenting to publish a popular handbook on the technical processes of mural painting." The resolution was unanimously carried.

#### Economic Arguments for the Encouragement of the Fine Arts.

Mr. Patrick Geddes, M.A., read a paper, in the course of which he said the congress was really a living voice of art, inasmuch as the papers had dealt not simply with questions of technique and materials, of art education, of increasing the quality and quantity of production—all internal questions—but had treated energetically external questions also. He argued that the claims and place of art had to be determined in no small measure upon purely scientific grounds, those of the supposed dismal science of political economy, and said the

task they had before them was to combine municipal and social life with that of their encouragement of the fine arts in a single movement—that of the new Renaissance, the revival of art and life. From the planning of cities to the magnificence of mural decoration and the modest claims of artisan dwellings, and furniture, and art for schools, these were henceforth the real problems of a reformed political economy, scientific and practical.

Mr. P. H. Rathbone remarked that it was because we had not been good political economists that we were now losing very rapidly our position as a manufacturing nation. It was not by cheapness but by the place we occupied in the artistic world that we could hope to keep our position in the future.

### THE MUSEUM SECTION OF THE ART CONGRESS.

MR. L. CUST presided in this section owing to the absence of Mr. Sidney Colvin. He spoke of an ideal museum, and proposed the creation of a Governmental department entirely set apart to attend to the art education of the people; he would have each of our great art institutions under the management of one man, who was recognised throughout the world as the greatest living authority on the subject over which he had control, and this manager should engage himself in the education of others to occupy similar positions; he would have special attention given in the museums of provincial towns to the collection of objects of local interest, having objects of national interest deposited in the national collection; he would have lectures every evening; he would have the museums open on Sundays, and lectures—with special reference to the wants and requirements of the working classes—given therein on Sunday evenings.

#### Art Museums.

A paper on "The Economical Formation of Art Museums for the People," contributed by Mr. George Wallis, F.S.A., of the South Kensington Museum, was read by Mr. Whitworth Wallis. It was pointed out that only museums with the funds of a Government or wealthy corporation at their back could secure important original objects of art when these were brought up for public competition. The question arose, "Is it absolutely necessary that every object in a museum should be original in order that it may be of educational value to the people?" Mr. Wallis's experience had led him to the conclusion that much might be done for the cultivation of a popular taste in the best and highest forms of art without the expenditure of large sums of money on important original works, and at the present time facilities for procuring reproductions of originals had been largely increased of late years, thanks to the increasing number of museums on the Continent, and by the system of international exchange organised by the Science and Art Department. The vulgar, degrading, and factitious admiration of an object because it had cost a large sum of money, and was said to be valued at a higher price, would be got rid of in such a collection of reproductions, and the æsthetic qualities of art as representative of nature and the genius of bygone ages would have a chance of being recognised and appreciated. Of course that was said on the assumption that the originals represented were themselves works of art, and worthy of being reproduced as examples by the best methods.

#### Elementary Schools and Art Galleries.

Mr. T. C. Horsfall read a paper in which he said that to gain knowledge and love of art, we must in early life see beautiful things; while we see them their beauty must be pointed out to us, and we should have our attention strongly directed to them by learning to draw. These conditions obviously could not be created for workpeople unless elementary schools were supplied with small collections of pictures, and with teachers themselves interested in art; unless school children were also taken sometimes to art galleries and to places where they could see something of the beauty of nature, and unless, further, drawing from beautiful objects be taught in all elementary schools. It was of great importance that children should gain knowledge of nature, of whose beauty and interest the majority of the inhabitants of large towns were quite ignorant.

#### Lessons from France.

Mr. Philip H. Rathbone in his paper insisted that it was necessary that Government should exert itself to enable the people to speak the language of their literature, and the time would come when art would be considered as necessary a branch of education as reading and writing. Paris had understood that, and the consequence was that, although France had passed through a most disastrous war which would probably have ruined London, Paris still claimed the position of leader of civilisation in the world. The course of study carried on at the art schools of Paris consisted of two kinds—those intended to educate painters, sculptors, and architects, and those intended for artisans employed in the decorative arts, masons,

pottery, iron and bronzeworkers, cabinetmakers, house-painters, paper-stainers, weavers, &c. Of the second class some were maintained by the Government and some by the municipality of Paris, but all were free. In Paris also the municipality spent very large sums annually in decorating their public buildings by historical or national pictures, and contrasting that with this country he instanced Liverpool, pointing out that not one penny of the cost of the permanent collection of pictures and statuary, and the building in which they were displayed, did they owe to the Council of Liverpool. The people of Liverpool and the artists had, however, done the work well, for they had pictures to the catalogue value of 22,000*l.* bought out of the profits of the exhibitions. Moreover, they had had hard work to prevent a portion of those being grabbed for other purposes, and had even been refused the  $\frac{1}{2}$ *d.* in the pound necessary to give any proportionate amount of efficiency to that institution, which represented a population of 600,000 inhabitants. In a letter which he had received from Mr. Mundella, he said:—"I am the only Minister who ever obtained a grant in aid of provincial museums, and when I demanded its restoration last week what aid did I get from Liverpool? Roscoe I can always count upon, but 'where are the nine?' Why do you not stir up your local M.P.'s against this degrading economy?" In conclusion, Mr. Rathbone gave a list of the necessary examples of the famous art works which would give a complete means of study of architecture and sculpture suitable for Liverpool.

### BIRMINGHAM ARCHITECTURAL ASSOCIATION.

A MEETING of this Association was held at Queen's College on the 4th inst. It was announced that special prizes were offered to the student members by Mr. Naden (president) and Mr. Doubleday (vice-president) for the best-measured drawings of old buildings, and by Mr. Newton for the best design for a house, the particulars of the competition for which would be issued to members at once. A paper written by Mr. Ponting, F.S.A., of Marlborough, was in his absence read by Mr. H. R. Lloyd. The writer gave a detailed account of Edington Church, Wilts, describing it as the first example of transition from the Decorated to the Perpendicular style, and claiming for its designer, Bishop Edington, the merit of originating the latter style. The paper was illustrated by a number of excellent drawings of the church, and was followed by a short discussion and a hearty vote of thanks to the writer.

### SOCIETY OF ENGINEERS.

THE thirty-fourth annual general meeting of the Society of Engineers was held on Monday. The chair was occupied by Mr. A. T. Walmisley, president. The following gentlemen were elected as the Council and officers for the ensuing year, viz.:—President, Mr. Jonathan R. Baillie; vice-presidents, Mr. Henry Adams, Mr. R. W. Peregrine Birch, and Mr. William Newby Colam; ordinary members of Council, Messrs. Chris. Anderson, James Henry Cunningham, George A. Goodwin, Robert Harris, James William Restler, William Schöneyder, William Andrew Valon, and Joseph William Wilson, jun.; as honorary secretary and treasurer, Mr. Alfred Williams; as honorary auditor, Mr. Alfred Lass (Messrs. Alfred Lass & Co.). The proceedings were terminated by a general vote of thanks to the Council and officers for 1888.

PROPOSED EXTENSION OF GREY STREET AND GRAINGER STREET, NEWCASTLE-ON-TYNE.

THIS design has been prepared for the promoters of the scheme for an extension of Grey and Grainger Streets to St. Thomas's Street, in the Haymarket. The two before-mentioned streets were constructed by the late Mr. RICHARD GRAINGER, of Newcastle, who took so prominent an interest in the architectural development of the city. This extension, of which the drawing shows a sketch view, was no doubt for some time previous to his death contemplated by Mr. GRAINGER. On the completion of this work it may be safely asserted that few towns or cities in the kingdom will present a finer array of buildings or noble streets than Newcastle-on-Tyne.

## NOTES AND COMMENTS.

THE courses in the Collège de France relating to art and archæology were commenced last week. M. MASPERO will treat of the archæology of Egypt, and M. OPPERT the archæology of Assyria. M. FOUCART takes the course on the antiquities and inscriptions of Greece; and a special course on the Acropolis of Athens will be given by M. HOMOLLE. M. CAGNAT's course will be devoted to subjects relating to the history of Rome. Lastly, M. EUGÈNE GUILLAUME, the sculptor, takes Italian painting at the beginning of the sixteenth century as the subject of his course. It is needless to say that the lectures in the Collège de France—and there are between twenty and thirty professors of the highest standing—are always gratuitous. The college was founded by FRANCIS I. in 1529, and some of the most renowned scholars and men of science are associated with its history.

THE late Professor PALEY was so well known as an editor of Greek and Roman classics, and as in this country we suppose a man can only do one sort of work, it was not surprising that the notices of his life made no mention of his architectural writings. His book on "Mouldings" has not been superseded, but he wrote much more about the art. Professor PALEY was one of the most ardent advocates of the Gothic revival, and he did good work in drawing attention by means of essays and tales to the neglected condition of English churches some forty years ago. His guide to Peterborough Cathedral is still found useful by visitors. Ancient literature was of course his chief task, and as a commentator and editor he upheld the old reputation of this country. Professor PALEY was a brother of Mr. PALEY the architect, who was a partner of EDMUND SHARPE.

FRENCHMEN are becoming alarmed about the danger which awaits the old church of St. Martin de' Monti in Rome. It is not much known to strangers, but it is one of the few churches embellished with landscape-paintings in fresco. The subjects are taken from the history of ELIJAH. Twenty-four landscapes were painted by GASPARD DUGHET, who assumed the name of POUSSIN, and the figures were put in by his famous brother-in-law, NICOLAS POUSSIN. The church has also an underground oratory and catacombs. A new street is in course of formation near the church; and as the civil engineers are not disposed to consider a church as sacred, the walls are so much shaken as to necessitate the suspension of services and the closure of the church. The plaster containing one of the frescoes has fallen in pieces, and the others are likely to follow if more precautions are not taken.

THE fire which broke out at Messrs. DOULTON's pottery in Lambeth on Tuesday has excited interest of an exceptional kind. It is felt that the damage is not to be measured by the loss in money. Messrs. DOULTON may be said to have created a new industry, for not only have they proved how much can be done in one branch of pottery, but they have also shown that the applications of art are not yet exhausted. They have created a school of designers, and fortunately they are not without imitators. In the fire this week many pieces of pottery were destroyed, but with the aid of the staff they can be replaced. The business of the firm is so extensive and so much prudence marks the arrangements, we may be sure that no inconvenience to the public can arise from the fire. The stock is always large. But good wishes for the speedy restoration of the works will be expressed throughout the country.

As the late Duchesse DE GALLIERA expended more money than any lady of our time upon building and construction, her death should not be allowed to pass unnoticed in this journal. The name of the Duchesse does not, moreover, appear for the first time in *The Architect*, as the fine series of illustrations of the "Cities of Italy" which we published in 1873 were from paintings by PAUL BAUDRY in the mansion of the Duchesse in the Rue de Varennes. The Duchesse was born in Genoa, and that city owes much to her liberality. A sum of 25,000,000 francs was

expended on the harbour, the mansion belonging to the Duc, with its contents, a gift valued at 7,000,000 francs, was made over to Genoa, and in addition two hospitals were constructed at a cost of 7,000,000 francs. In Paris the erection of the Musée Galliera cost 5,000,000 francs, and a still larger sum would have been expended but for an error in drafting a deed by which the Musée became the property of the city, when the donor's intention was to enrich the State. Two blocks of workmen's houses cost 2,000,000 francs; 11,000,000 francs were spent on the erection and endowment of the Hôpital de Clamart, and no less than 24,000,000 francs upon the erection and endowment of an orphanage at Fleury, and an asylum at Meudon. The Duc was known as a great railway contractor and speculator, and is said to have left a fortune to his widow that was valued at nine millions sterling. The greater part of that vast sum has been expended for benevolent purposes, and builders have reason to regret the loss of so munificent an enthusiast.

THE care which is now bestowed on the decoration of steam-vessels is exemplified fully in one of the latest additions to the Castle Mail Packet Company's fleet. The *Roslin Castle*, which is now on her way to the Cape after alterations, was decorated from the designs of Mr. G. DUNCAN, of London. In the principal saloon the prevailing tone is a soft bluish grey, intermixed with vellum tints and relieved with gold, blending harmoniously with the rich satinwood panelling. The iron girders which support the ceiling and upper deck have been treated with gold and the above-mentioned colours. Portraits of MILTON, HOGARTH, WREN, BEETHOVEN, and other celebrities, painted by an everlasting process on raw sycamore wood, have been introduced with happy effect round the lining of the skylight. The ladies' boudoir is sumptuously upholstered with green brocatelle, and is panelled with cedar and sycamore. The new ceiling in the principal smoking-room, with its octagonal panels, is exceedingly rich in colour. The walls of the spacious ventilating shaft are of a bluish grey, stencilled with a rich design in a similar, though lighter, colour in imitation of flowered silk. All the state-rooms have been handsomely enamelled and decorated.

THE five designers who are to take part in the second competition for the diploma of the Paris International Exhibition are MM. LOUIS BONNIER, architect; HENRI DANGER, of the Ecole de Rome; DANIEL DUPUIS, engraver; GEORGES DUVAL, architect; PIERRE VICTOR GALLAND, painter; and MICHEL LANÇON, sculptor. M. GALLAND's name is well known, but the other competitors have yet to gain renown. The first designs have given rise to much disappointment. What was most remarked in them was the general absence of any recognition of the purpose for which the diploma was intended. As was to be expected, the failure has given rise to attack against the official system of art education. The second designs are to be lodged in Paris before February 1, and if one is accepted the artist will receive 10,000 francs.

THE Sèvres vase which M. CARNOT offered as a prize in connection with the Black and White Exhibition of Paris has been awarded to M. LEVEILLÉ, the wood-engraver. The jury considered it should be the prize of an artist who had already received a recompense of a different kind. The gold medal of this year's exhibition was gained by M. KARL ROBERT, who, it appears, is the son of M. MATHIEU MEUSNIER, the sculptor.

THE Belgians have an expectation that their section of the Paris International will be superior to all but the French division. M. JANLET, who designed the façade of the Belgian building at the exhibition of 1878 is the architect. In order to produce exceptional effect, it is decided that all the cases for the exhibitors are to be uniform in style. The Belgian armourers are expected to make a fine display of weapons of all classes. About 1,600 feet of rails will be laid down for the exhibition of the rolling stock of railways. All the industries will be represented in the machinery hall. Belgium will have about 2,000 exhibitors.

## PAINTING AT THE ART CONGRESS.

THE subject of a paper by Mr. F. Bate was "The Tendencies of Modern Art." He advocated a more thorough and intimate relation between artists and workmen, for in the applied arts the artists who did not know the technical details of work were worse than useless, and the same might be said of the workman who had no knowledge of art. It was said that there were 12,000 professional artists in London alone, and yet the proprietor of an illustrated paper, who spent 500*l.* a week on illustrations, said that in spite of this fact he had to look to France and elsewhere for his artists' staff. With regard to art education, he asked what had the Royal Academy done in this direction? and asserted that the Royal Academy Schools did not take a high rank as a teaching institution in the world. Then, again, in the election of members, in the acceptance of works for exhibition, the Royal Academy had been unfair, illiberal, and narrow-minded.

Mr. Alma-Tadema said he was rather afraid the tendencies of the reader of the paper were against the Royal Academy. It could not be helped. The question of art education was a very difficult question, which one could hardly in a few moments discuss, but which one might give a few flying thoughts upon. They were forced to the conclusion that no education by machinery would be complete, because its value could only be judged after it had produced its results. Theoretically, principles in those matters could only prove their true value by the results they produced; therefore Englishmen found that the Royal Academy, which was established on the same principles as the academies of other countries, was not sufficient, and therefore the system of governmental art schools was introduced. Those schools had influenced the country greatly, and, as they had heard, those schools had not answered the purpose for which they were founded, because experience taught them that those admirably trained pupils were not practical enough; they did not know enough of the way in which their drawings ought to be applied. He knew that the Royal Academy was a poor body—they did not represent anything outside their own body, and had left a great many artists outside. But still the Academy had produced such artists as Sir John Millais and Mr. Frank Holl, both pupils and medallists of the Academy. He thought the Academy had still a little bit of love for art left in it; they of the Academy tried and did their best to teach their pupils, so that they need not go to France to learn to paint pictures of sand with a little bit of grass and a figure in the foreground. He thought that a country who could boast of a Reynolds, a Turner, a Constable, a Millais, a Holl, and many others who were all taught at home, need not fear for the future of its art.

Mr. Brett, A.R.A., said he had an acquaintance of fifty years of the Royal Academy, and the only education in art he had had was got from the Royal Academy, and he said they would have no art in England at all but for the Royal Academy.

## The Emancipation of the Picture.

Mr. Reginald Hallward read a paper on "The Emancipation of the Picture." He declared that the cause of the existing depression in the painter's art was not primary economic, but intellectual. The standard of excellence was not high enough, and the bulk of pictures indicated intellectual inferiority. He attributed great blame to the Royal Academy, the accepted representative body which but recently opened its doors still wider for the encouragement of the painter of pictures. The attitude of the Academy towards all this handicraft attempt, the product of the schools, had been one both of carelessness and misdirection, proved by its persistent encouragement of work in a false direction. To the Academy they must look for these reforms which would make its control wise and effective, and first of all in the matter of reform must come the curtailment of the number of pictures exhibited, and the raising of the standard of work by higher tests. Art must be allowed to develop in new quarters, and the Academy must limit the gross and unexampled encouragement of mediocrity in the painter's art.

## Art Education.

Mr. Holman Hunt read a paper on this subject. He said the system of instruction at the Royal Academy and also at the South Kensington schools failed to have the highest results because there was no bond of interest and affection between the student and the master. The most excellent system that ever existed in the world was that pursued by the old masters, who had their students in their own studios. It was often carelessly said that the French still preserved this principle of instruction, but this was a great mistake. The English teaching in the life and the painting schools given in monthly courses by the best masters was interesting, and a really unprejudiced and painstaking student might derive much instruction from them if the original intention were fully acted up to. But his impression was that the really desirable masters generally deputed a substitute glad of a guinea to act for them. With

regard to the present position of art in this country, he said the real cause of complaint was that our taste was not independent enough; it was frightened by the oracles of taste, and so became unsettled and lukewarm. It was not considered that in the long future England would be judged by the art it leaves. Some of the evils of the present day, such as the excess of students, were scarcely under their control, although he strenuously suggested an inquiry as to whether the giving of medals in art schools was not fraught with evil, as encouraging mediocrity. A lad on being thus rewarded for skill of a very elementary kind was easily persuaded to believe himself a genius. Mr. Holman Hunt referring again to the Royal Academy, and as an example of the encroachments of which this amiable body could be guilty, he pointed to an innovation lately made at Manchester and Liverpool. A work by an R.A. had inadvertently been rejected at an exhibition in one of these cities, and in order that this should never occur again, the Academy Council had made an arrangement by which a member of the Academy should henceforth be annually supplied to the provincial committees. This central system he stoutly protested against. The conclusion of the whole matter was that the Academy must be persuaded to adopt a system that would better represent the profession. In concluding, he referred to Sir F. Leighton's opening address, with which he quite agreed, except his laudation of the French nation, as opposed to our people, as having an exceptional sense of beauty. That the French had had great artists he admitted, and also that they were tasty and neat, that their women could put on a cap and their cooks serve up a dish with great daintiness. But he did not regard their decorative work as worthy, and their paintings were so often merely illustrations of a page in history, or dull and ugly old men playing cards or chess, without a spark of beauty. We must avoid too narrow an interpretation of the word beauty, but they must refuse to recognise brutal and sensual art.

## Pictorial and Decorative Art.

Mr. John Brett, A.R.A., read a paper, his object being to show that decoration meant merely artistic completion of a useful structure, and was not a separate art of itself. Fine art was generally supposed to comprise the pictorial, the plastic, and the architectural arts; but he did not think that classification altogether philosophical, inasmuch as architecture was primarily utilitarian, and clearly transgressed in some respects the definition of fine art. As regarded sculpture, in the best periods it had always been associated with architecture, and constituted the noblest form of decoration. It appeared, therefore, that unless they could find a better definition for the term "fine art," it was only applicable strictly to pictures. Good decoration depended upon the adaption of organic forms to a geometrical structure, but for this purpose the imitation of natural objects would not answer, for two reasons. The first was that beautiful natural objects were too difficult to reproduce, and therefore too expensive; the second that they required to be infected with the inorganic or crystalline motive, so as to make them harmonise with the geometrical contours and take them out of competition with reality, a competition in which their necessary failings would show a painful shortcoming. It was also desirable that the images should not be thrown together haphazard, but composed so as to show purpose and taste—that was to say, set in order with rhythmical sequence and cadence. The pictorial art, on the other hand, while admitting to a certain extent of that sort of discipline and constraint in the disposition of the images and areas of colour, put itself deliberately into competition with nature, and in its highest achievements quite successfully. The truth about the pictorial art was, he believed, that however earnestly the artist might wish to give a faithful resemblance of nature, some bias from his individual taste was inevitable. He emphatically stated that good decorative art was not any nearer the reach of the masses or the poor or moderately poor working people than was good fine art, for the cheap process of the factory could not produce it. A great decorative epoch was one in which all the workpeople engaged on a building or in the making of garments had free license to indulge their individual taste, and, as far as he could judge, that was incompatible with factory practice. The art-worker must still fight for his own hand. If he depended on the direction of the manufacturer, he thought he would soon become a manufacturer too, and the art would evaporate from his work.

Mr. Brett's paper did not give satisfaction to the section, especially the remarks in which the dignity of a fine art was no allowed to architecture.

Mr. James T. Watts protested against a tendency of the congress to underrate the dignity and influence of the pictorial arts in favour of the minor decorative arts. Without disparaging decorative art, let them always remember that pictorial art in addition to giving æsthetic delights of light and colour could and did excite definite emotion, and convey definite ideas no other arts could—notwithstanding Sir Frederick Leighton's apparent statement to the contrary. Hunt's *Light of the World*,

G. F. Watt's *Love and Life* and *The Worship of Mammon* exercised a wide and noble influence by exciting emotion and conveying ideas. He regretted to see artists themselves so readily abdicating their higher functions, and said that as "conduct was three-fourths of life," the pictorial arts, in ceasing to try to influence conduct, were surrendering their chief claim to serious consideration. Yet even when so limited, they remain the apex of decoration.

#### A Strict Method for the Study of the Figure.

A paper contributed by Mr. W. B. Richmond, A.R.A., was read by Mr. Clausen. The writer said it would be better to find out where the old art gained and the new art has lost than to fold their hands in despair. That an artist could be made by education none could admit, but that he could be hampered, chilled, discouraged, and retarded by want of intelligent direction in his studies, most would allow. A man who had no ideas should not dream of being an artist; and it followed, therefore, that it was most important to give a student as much as possible the opportunities to follow his own bent, that whatever there might be in him to say should be said in his own vernacular; much more than that there was not in the power of education to give. He asked were not their modern systems of drawing life studies, simply for the sake of doing them, a very faulty idea, and there could be no doubt that rapid studies of movement embracing many views of a moving object would be more stimulating to the intelligence than copying one surface of the same could be. If that was true, why in the name of all that was rational did they persist in pinning their art students down to one view of a model for weeks of stumping or stippling? The writer then referred to the "botega" or artist's workshops of the flourishing and living period of Italian art, and said that their picture-painting did not take excessive precedence over the "crafts" as, unfortunately, it did now in the social mind. Art of every kind was then welded and bound together by the love for the beautiful, and all art workers in worthy emulation desired the crown of success for their achievements. They, therefore, hailed with pleasure such a society as the Arts and Crafts, whose exhibition that autumn had given all true lovers of design not only pleasure but hope—hope that slowly but surely might come a better time, when they might once again, as of old, be ruled by the necessity of beauty in every article of common use.

Mr. Wardlaw Laing said that as an old student no one could more cordially agree with the remarks in Mr. Richmond's paper, for he had always believed in some such supplementary training to the Academy teaching as Mr. Richmond suggested.

Mr. Phil Morris, A.R.A., condemned the practice of working so long from the antique in the Academy training, and said that the students worked so long from the antique that they became nothing more than draughtsmen from the cast. He recommended art schools to teach drawing from the life in preference to the antique, for it was more stimulative to the mind. He thought that it was to realism they must look in the future to help art, for it was only when a realistic painter rose that they got the true vitality of art.

Mr. H. Morris said that beginners found a difficulty in making a tone, and mechanical means must be adopted in the first instance.

Mr. Gilbert, A.R.A., said that in art education all means were justified by the end. They might teach as much as they liked, but they would never make an artist.

#### Next Year's Congress.

At a meeting of the members of the central committee it was unanimously resolved to elect as President of next year's congress at Edinburgh, Sir William Fettes Douglas, president of the Royal Scotch Academy.

President Conway read over a list of the committee whom it was suggested should be elected to arrange for next year's congress, when a member of the committee declared his firm conviction that it would be fatal to the Association if appointments were made in this way, regardless of the feeling of the locality in which the congress was to be held.

Mr. John Dun said he was afraid when the congress was over they would be told that they had nothing to show for it. He would certainly like to see some practical outcome.

Mr. P. H. Rathbone said they should for one thing appoint a small committee to prepare for next year's congress a clear and succinct report concerning art schools of different places and countries.

A Meeting of the Tamworth Town Council was held on the 6th inst., when it was reported that Mr. Joyce, architect for the new municipal buildings, had been instructed to prepare bills of quantity in connection with the new buildings. It was objected to pay 2½ per cent. to the architect for getting out the quantities. One member said the general fee was 1½ per cent., and was paid by the builder. The report was finally adopted.

### ROYAL INSTITUTE OF BRITISH ARCHITECTS

THE third ordinary meeting of the Institute of Architects was held on Monday the 3rd inst., Mr. Thomas Worthington, vice-president, in the chair.

Mr. MACVICAR ANDERSON, hon. secretary, said that Mr. Lacy Ridge at the previous meeting asked if the Institute had discussed and sanctioned the regulations drawn up for guidance in regard of the restoration of ancient buildings, and the hints to workmen in regard of the same, and he had replied at the time that the Institute had not. Mr. Ridge now by letter asked him to read an extract from the report of the committee to the Council in 1865, the adoption of which report Mr. Ridge said constituted formal action on the part of the Institute. Mr. Anderson read the extract, and observed that in his opinion there was a wide distinction between a paragraph in a report showing what action the Council had taken, and the discussion of a subject formally brought before the Institute.

The Secretary pointed to a medal and diploma of honour sent by Sir H. Sandford on the part of the authorities in Adelaide, in recognition of the photographs sent to the Exhibition there.

#### The Examinations.

The SECRETARY said that the November examination for the Associateship began on Monday, November 26, and concluded on Saturday, the 1st instant, when 31 out of 38 candidates who presented themselves passed and became qualified for nomination in the usual way as Associates of the Institute, namely, Messrs. H. W. Burrows, R. Langton Cole, S. A. Ell, T. Phillips Figgis, John Gethin (Penarth), M. A. Green, H. Griffiths (Sutton, Surrey), J. W. Gunnis, John Hudson, E. W. Jennings (Swansea), F. L. Jones (Queensland), C. Oury King, S. Inskip Ladds, H. V. Lanchester, R. S. Lorimer (Edinburgh), J. A. Macara, W. A. Moule (Brentwood), J. E. Newberry, G. J. Oakeshott, A. S. Parker (Exeter), W. Pywell, T. P. Roberts (Bristol), A. E. Taylor, W. S. Taylor, H. H. Thomson (Leicester), H. Tooley, F. W. Troup, Paul Waterhouse, W. R. Wells, W. A. Williams (Mountfield, Sussex), R. Willock.

Time did not allow the consideration on Saturday of the Ashpitel prize, but the Board of Examiners were to meet shortly, and an early announcement of their award would be made to the Institute.

#### Scientific Masonry Prizes.

The Secretary announced that three members of the Council had offered prizes, to be entitled "Scientific Masonry Prizes," as follows:—A prize of 10 guineas, and a second prize of 5 guineas, to be awarded to any British architect or student of architecture who produces, to the satisfaction of the Council, the best work on the following subject, namely, a design for the vaulting of an entrance-hall to a public building. The work must be sent in to the secretaries before 2 P.M. on March 30 next. Only candidates whose drawings and reports have been considered satisfactory will be asked to produce a model of the structure.

#### St. Mary-le-Strand.

Mr. MACVICAR ANDERSON said he thought that all would agree with him that the removal of the church of St. Mary-le-Strand, which had stood too long in ruinous condition, would be nothing short of a national calamity. There were Goths who desired it should be removed on the score that it impeded the traffic, &c. The allegations made he had from time to time taken on himself to disprove. The narrowest part of a bottle was the neck, and the narrowest part of the Strand was not at the church but that part opposite Mr. W. H. Smith's, and the neighbouring premises. The proper way would be to do away with the rubbishy houses that occupy the north side of the street. The street view, with the church, from whatever point it might be seen, was one of the finest in London. Being asked to do so he had examined the church, and found there would be no difficulty in renovating it at a reasonable cost. A meeting, which would be open to the public, was to be held on Wednesday at King's College, the Bishop of London in the chair, and he thought there would be no difficulty in getting the public to subscribe. He would like, therefore, to be in a position to show that he had the sympathy of the Institute in expressing the same views at the meeting as he had expressed that evening.

This desire received the hearty approval of the audience.

Mr. FRANCIS HOOPER, Associate, and holder of the Godwin Bursary, read a paper of which the following is an abstract:—

#### Building Control in Paris.

Mr. Hooper said that no English visitor to Paris could but have been struck with the care displayed in the laying out of the streets of the city, the regularity of the building frontages, and the admirable sites secured for many of its public buildings. The rapidity also with which land, bordering on thoroughfares newly opened by municipal improvements, is covered with well-constructed and dignified buildings, indicates the confidence of purchasers that their property will not be depreciated

by any action of their neighbours or of the municipal authorities. Leases of land for building purposes by private individuals are practically unknown in France, so that no restrictions exist such as are contained in many English building leases to prevent erections which would cause injury to an adjoining lessee on the same estate. Owing, also, to the subdivision of the land, it is seldom possible for an owner of property to effect local improvements for the mutual benefit of an estate and the community. Legislation, therefore, in regard to building operations, seeks to secure to building owners such protection in their mutual relations as shall not be injurious to the public, and at the same time affords to the community facilities for united action when improvements are required in any locality, either of a sanitary character, or to meet the demands of increasing traffic.

The French Civil Code of 1804 precisely defines the rights of respective owners of party-walls; it specifies the conditions under which openings for the admission of light may be made on sufferance in walls abutting on the boundary line, such being fitted with wire grilles and sashes glazed with obscured glass; the sills of such openings on the ground storey must be not less than 8 feet 6 inches above the floor level, and on the upper storeys not less than 6 feet 2 inches. It is further provided that no window-openings from which a view can be obtained over adjoining property (other than the roadway, which is regarded as common to all) shall be formed in a wall within 6 feet 2 inches of the boundary, if such is parallel to it, or 1 foot 11 inches if at a right or obtuse angle. Should a prescriptive right be secured by uninterrupted enjoyment of a window during thirty years, the adjoining owner in building must observe a distance of 6 feet 2 inches from the face of the wall, but is not restricted as to the height of his building beyond conformity with local by-laws. Such are the servitudes on land imposed by the Code of France.

The Alignment Act, which dates from 1607, gives power to municipal authorities to amend the lines of street-frontage by the adoption of a plan of alignment which imposes a servitude on all buildings in old streets which are in advance of the alignment, and preventing any structural repairs to foundations or walls as would prolong their existence before the alignment is effected. This Act, though slow in operation, has been adopted in many of the provincial towns with great advantage. Compensation is paid for the land contributed to the thoroughfare, but not for the buildings upon it, as these may be occupied until rebuilding becomes necessary, and the amount (if no amicable settlement be made) is awarded by the jury of expropriation, which in Paris is summoned about every six months to settle all disputes which await it. Should it occur that so much of a plot of ground is contributed to the street that it is impossible to erect a healthy building on the residue, the authorities are compelled to purchase the whole, and negotiations are made with the adjoining owner for the acquisition of the surplus, and he may, in turn, appeal to the jury for a valuation upon which he is willing to acquire it. In the event of the failure of all negotiations, the administration may obtain power to acquire the property of the adjoining owner by means of expropriation, and so deal with the two sites together. In Paris the Alignment Act is in constant operation, but the necessity for more rapid improvements leads both public and private bodies to seek powers for the immediate acquisition of property by the Expropriation Act of May 3, 1841, for works of public utility. The procedure involves the preparation of plans, in accordance with certain rules, to fully demonstrate the intentions of the promoters. These plans are exhibited to the public for fifteen days, in provincial cities at the town hall, in Paris at the Mairie of the arrondissement.

The exhibition is announced by advertisement in local newspapers and by placards in the district, and an agent is appointed by the Prefect of the Département to attend on his behalf, for three days, to receive and report all verbal and written observations made to him by those interested relating to the necessity or efficiency of the scheme. Should the promoters act on any of the suggestions made in the report, the revised plan is again exhibited; but otherwise it is at once transmitted by the Prefect, with the report and his observations, to the Minister of the Interior, and becomes operative with the approval of the Chief of the State. The scheme having been thus approved, the plan is again exhibited for eight days, to show the property required for its execution, thus affording an opportunity to all persons interested to verify the representation and description of their property, and to put themselves into communication with the promoters for the settlement of their claims to compensation. In the event of the promoters failing to secure an amicable settlement of the claims, application is made to the High Court of Justice for the appointment of a jury to fix the awards. The Act of June 4, 1853, provides that this "jury of expropriation" shall consist of twelve persons, having the same qualifications as in criminal cases—that is, being upwards of thirty years of age, and entitled to the parliamentary vote.

The Court appoints a judge (*magistrat-directeur*) to preside,

and summons sixteen jurymen, with four supplementary persons, whose names are made known to the claimants, together with the offers of compensation. The promoters and the claimants have each the right to cancel two names from the list of jurymen summoned, after which the first remaining twelve constitute the jury, which remains intact until all claims relating to the scheme are settled. The jury examines documents and witnesses, and also visits the property, and its award is binding on both parties, unless appeal is made within fifteen days to the Cour de Cassation, or High Court of Appeal, the costs being taxed by the judge.

Having cited the Acts under which powers are obtained for effecting municipal improvements, it is necessary now to add that the Alignment Act requires the permission of the Prefect of the Département to the erection of any building bordering on the public highway. The whole of the streets of Paris are classed as belonging to the highway, or Grande-Voie, and in consequence plans of every proposed building must be submitted to the Prefect of the Seine, and such buildings must conform to the by-laws of the Département.

A special staff of the Prefecture of the Seine is entrusted with the custody of the plan of Paris, and records all authorised realignments, so that when applications for permission to build are submitted to the Prefect the necessary conditions are defined in granting the sanction.

Many of the provisions of the Paris building by-laws are dependent on the strict alignments already referred to, the conditions varying with the effective or intended width of the streets. The height of a front wall in a street 65 feet 6 inches in width may be 65 feet 6 inches; but in a street of 25 feet 6 inches may not exceed 49 feet. A building, however, at the corner of streets of unequal width, may return along the narrower street for a distance of three times its width. No wall adjoining a thoroughfare may exceed a height of 65 feet 6 inches, even though facing a boulevard or open square. The roof above the façade must be contained within the perimeter of a semicircle drawn from the face of the wall, its centre being level with the top of the wall, and its radius equal to half the effective width of the street, but in no case exceeding 27 feet 6 inches. The minimum height of a room erected at the ground level is 9 feet 2 inches, and of the basement and upper storeys 8 feet 6 inches. Further, the storeys may not exceed seven in number above the ground, including attics. The minimum area of courtyards and air-shafts is regulated by the height of the enclosing walls. The legal projections of cornices, string-courses, plinths, balconies, &c., over the public thoroughfare are dependent on the width of the street in which they occur, and are measured from the street line, so that where greater projection is desired for the perfecting of a design it is necessary to set back the building; hence the flatness so detrimental to the effect of many of the Paris façades.

The *commissaires-voyers* of Paris, whose duties correspond to those of the district surveyor, are twenty in number, and each has charge of one of the arrondissements into which the city is divided, with an office at the local mairie.

The erection of buildings for the public service in Paris is usually entrusted to architects whose designs have been selected as a result of open or limited competition. Such buildings may be classed in three categories: those which belong to the Municipality, to the Département of the Seine, and to the State. The appointment of architects for the two former is subject to the approval of the Prefect. The first category comprises the mairie, or offices of each arrondissement, the markets, day schools, public libraries, hospitals, mortuaries, &c. The control and maintenance of these buildings after completion are entrusted to ten architects, each having charge of two arrondissements of the city, and responsible to a superintending architect at the Prefecture of the Seine, and each has the title of *architecte de la ville*. The buildings belonging to the Département comprises the workhouses, reformatories, courts of justice, the residence of the Prefect, &c., and are under the control of two architects charged with their maintenance. The buildings of the State comprise the national palaces, museums, picture galleries, monuments, houses of parliament, public offices, &c., and are each severally in charge of an architect appointed by the Minister of Fine Arts, and are responsible to the Director of Works of Civil Buildings.

The Prefect of the Département of the Seine is advised on all important questions affecting the architecture of the city of Paris by the Conseil d'Architecture, or Standing Council of Architecture, which is attached to the Prefecture, nominated and presided over by the Prefect. It is composed of four of the senior architects in active service attached to the Prefecture, with five honorary architects who are on the retired list, having spent thirty years in the service or reached sixty years of age, together with independent architects, amongst whom are at the present time MM. Charles Garnier and Bailly, both members of the Institut de France. Meetings are held weekly, and the remuneration of the members is by a nominal fee on attendance (*jeton de présence*). On questions such as concern the

construction of railways, canals, drainage, &c., the Prefect of the Seine is advised by the Council of Engineers attached to the Prefecture, which is composed of experts, nominated and presided over as in the case of the Architectural Council.

The Ministers of State are advised on all important architectural questions, such as sites and plans for new public buildings and monuments, the laying out of new thoroughfares, and the improvement of old streets by the Conseil-général des bâtiments civils, or General Council for Building, which is a standing architectural council attached to the Ministry of the Fine Arts, and composed of the Director of Works of Civil Buildings, four inspectors-general of that service, and four distinguished architects nominated by the Minister. The director and inspectors are permanent members, whilst half of the temporary members retire annually, and are not eligible for reappointment as members until after an interval of two years. All are paid a fixed fee annually for their services, and the appointment as a member is one of the highest architectural distinctions. The present permanent members who are inspectors-general (the late M. Questel's place has not yet been refilled) are the following:—

M. Garnier, M. André, and M. Diet, all members of the Institut.

The temporary members for 1888 are the following:—M. Faure, M. Moyaux, M. Le Clerc, and M. Bernier. Acting on the advice of competent professional judgment, State officials are relieved of much personal responsibility, and the public enjoy the security which such advice affords for the wise administration and expenditure of funds.

Mr. WILLIAM WOODWARD said the paper came at an opportune moment, when London was in a state of transition in its management with the advent of the County Council. The paper endorsed a view held by many, that London architecture was spoiled by rights of light and air enforced by adjoining owners. If litigation arose, it was entirely the fault of architects themselves. Architects knew what rights pertained to neighbours, and it lay within their control to design the buildings so as not to interfere with neighbour's rights. The question of alignment was absolutely essential to the well-being of every city. Much that was to be regretted in carrying out improvements in London would have been avoided if the French regulations were in force here. As it was, the public remained in ignorance till it was too late to correct the evils. The desirable custom of exhibiting the plans was one adopted in Rome as well as in Paris. Mr. Woodward referred to the laying out of new streets, and instanced the new street from Holborn Town Hall to Islington, which should have been laid out in the first place wide enough to carry the traffic. Under an Act of George II. the street from Islington to Paddington had been formed, and there was a stipulation that any building which encroached over the line of frontage should be pulled down as a common nuisance. Within the last three months an application had been made to the Metropolitan Board of Works for leave to erect a structure projecting 35 feet beyond the line of frontage. The Board of Works forwarded the application to the Marylebone vestry, who would not consent, yet in face of the opposition of the local authority and of the Act of George II., the Board of Works had absolutely consented to the encroachment. The disfigurement of that magnificent avenue was then only a question of time. Public criticism would have prevented such a scandal. In any future legislation care should be taken not to hamper architects too much, or they would have the same dull monotony as in Paris. Speaking of the French system of designing public buildings, Mr. Woodward thought it might be useful here, for they could not always count on having a Mr. Taylor and a Mr. Tanner, whose works designed as departmental office would compare favourably with those of independent architects. He concluded by saying that the church of St. Mary-le-Strand was, with Mr. Anderson, in safe hands.

Mr. CHARLES FOWLER remarked that the Metropolitan Board in 1874 proposed an amendment to the Building Act containing provisions to limit the height of buildings. That was opposed, and witnesses brought forward—among them the late Mr. Barry—by the opponents, with the result that the Bill was thrown out. It was also a point with the Select Committee of the House of Commons, who did not think it fitting that the height of buildings should be limited. He agreed with Mr. Woodward that any subsequent legislation should be carefully framed so as not to interfere with architecture. The short Bill to limit height of buildings was crude and negligently prepared. There was no standard by which to determine limits of height. It would not pass, but it showed what was in the air, and the Institute should see that future legislation took the right course. To his mind the obtaining a right of light by prescription had always seemed the obtaining of something for nothing, an arrangement neither lawful or moral. It would be better to be without it altogether, or at least that the right should be modified.

Professor KERR said the feature that struck him most was that in the whole administration of architecture in Paris the

architects governed. In England the liberty of the subject was so sacred that we were jealous of its being interfered with in the most modest way. When the Metropolitan Board was established it followed this old system in all honesty. The members had come together with more honesty and intelligence than they had been credited with. But the Board did not refer architectural matters to architects. They did not allow Mr. Vulliamy architectural authority. That would have been contrary to the English method, though when they got into trouble they shifted the blame to architects. The misfortune in England was that architects were not referred to. In France architects were universally referred to. The splendour in France was no more costly than our ugliness here. Much would be effected for good if architects here were admitted to some small share of authority.

Mr. R. PHENÉ SPIERS, F.S.A., referred to the church of St. Julien des Pauvres, which was going to be pulled down, and the opportunity of drawing and measuring it before it should be too late.

Mr. T. BLASHILL said the County Council would, at any rate, have the opportunity of doing useful service. It was well to know what was done in other countries; but, even so, the conditions were different, and we could not be supposed to adopt other methods without consideration. The Institute of Architects, as Professor Kerr had said, did not come to conclusions. If it did so it would have more influence than any official body in London. No public body here could carry out public improvements in the reckless way private investors could. They always had the fear that they would be spending too much of the public money and increasing the rates and taxes. Mr. Blashill then suggested that critics should inform themselves of facts before committing themselves to criticism. The acquisition of a bit of land apparently involved no great expenditure. But let any one once learn the amount of compensation that owners asked for, and he would find out how costly it was. To go to arbitration generally made matters worse. As to width of streets, there was no street that was not found too narrow as soon as it was opened and traffic developed. Mr. Woodward was wrong in saying that the new street had to take the whole traffic of Gray's Inn Road. It took only half at most, as it was now divided between two streets. He did not say, though, that they were wide enough. Mr. Woodward also forgot that the Act of George II. had been repealed in 1855.

Mr. WOODWARD asked leave to state that he had said that in addition to traffic from Gray's Inn Road, the whole of the traffic of Shaftesbury Avenue and the new Clerkenwell Road had to be carried. The question whether the Act of George II. had been repealed or not was still before the lawyers. The gravest matter of all, that of permitting the encroachment, Mr. Blashill had passed over in silence.

Mr. LOVEGROVE and another Member made a few remarks, after which a vote of thanks to Mr. Hooper for his paper, on the initiative of Professor Kerr and Mr. Fowler, was passed by acclamation.

Mr. HOOPER having replied, the meeting was adjourned.

#### THE ROYAL SCOTTISH ACADEMY.

THE Associates of the Royal Scottish Academy lately sent the following memorial asking for a reform of the Academy:—

*Unto the President and Council and the General Assembly of the Academicians of the Royal Scottish Academy. The Petition of the undersigned Associates of the Royal Scottish Academy*

Humbly sheweth,—That the primary object of the institution of the Royal Scottish Academy is to promote the advancement of the fine arts in Scotland, and to afford facilities, by means of schools, for the prosecution of the studies of painting, sculpture, and architecture, and other branches of art connected with these studies.

That by the constitution and laws of the Royal Scottish Academy the Associates (while they have a deep and growing interest in its objects, as defined by its constitution, and have, in addition, this important interest in its funds, that they and their widows are entitled to participate in the benefits of its pension fund) have no voice in the government of the Academy, or in the election of its members.

That your petitioners desire to bring before the President and Council and General Assembly the advisability of widening the basis of the Academy, of enlarging its area of usefulness, and of attaching to it by a closer tie the large and increasing body of Scottish artists, who are at present without adequate prospect of being brought within its sphere of usefulness.

That your petitioners believe these artists might, with enormous advantage to the Academy itself, be in some way

associated therewith, and allowed to feel that they are adding to the strength of, and assisting to extend an institution which, in its true aims and objects, is worthy of the highest support.

That your petitioners are assured that any steps in this direction would necessarily encourage and foster what all would desire to see, namely, the establishment of a flourishing school of art, which would retain its hold upon students, who at present find it necessary to complete their studies elsewhere.

That your petitioners humbly venture to suggest that the objects above referred to would be best and most easily attained by such an amendment of the constitution as would involve:—

- (1) No limitation to the number of Associates, so that, in the event of several artists of distinguished merit being candidates, their admission should not be delayed; while, on the other hand, if no such person be upon the list for the time being, an election need not necessarily take place.
- (2) Giving Associates a vote in the election of Associates.
- (3) Rendering Associates eligible for teaching and other duties in the Academy's schools.
- (4) Giving effect to the existing law providing for the establishment of a school for the study of the antique.
- (5) The addition of two representative Associates to the Council of the Academy, and of one Associate to the Hanging Committee; and that the usual abstract of accounts, as issued to Academicians, should be likewise sent to each Associate.
- (6) Allowing the name of a candidate for Associateship to remain upon the list until he withdraw it.
- (7) Providing that no member of the Academy shall contribute more than five works of art to the annual Exhibition, and no outsider more than three; and
- (8) The precise definition in the laws of the Academy of the meaning of the term "Members."

May it therefore please the President and Council and the General Assembly of the Academicians to take the premises into consideration, and to take such steps as they may deem expedient, and as may be necessary, for giving effect to the petitioners' suggestions.

And your petitioners will ever pray, &c.

The reply states that "The Academy is at present engaged in the consideration of the steps necessary to forming a new charter, and of the alterations in the terms of the present charter which it is desirable to embody in it."

### THE ROYAL ACADEMY SCHOOLS.

THE prizes gained by the students, both male and female at the Royal Academy Schools, were distributed on Monday night by Sir Frederick Leighton, P.R.A.

The President said he had not this year to ask them to listen to an address from him, but he would detain them for a few moments with some remarks on the general character of the competition. In the various classes there were various degrees of excellence. In some subjects they had not passed the average level of past years, and in one class of competition no prize had been awarded on account of the high standard which it was desired to maintain in that particular class. On the other hand, in some branches of study the results were excellent—as, for instance, in sculpture, in which the work done was fully up to the steady level of improvement which had been noticeable for years past. For the paintings from life a *proxime accessit* had been added, as the competition was very keen, and in the cartoon of a draped figure the work had been exceedingly good. In the designs for the decoration of a public building the average, which was a very high one, had been kept up. Before passing on to the announcement of the names of the successful students, he would repeat what he had said on former occasions to those who would go away empty-handed. He would bid them remember that the resolutions of the members were not hastily arrived at, and that it was after much labour and trouble and weighing of merits that the line was drawn which divided the successful from the unsuccessful. Of one thing he was sure, and that was that, with that generosity which always characterised the youth of England, they would heartily applaud the more fortunate among their fellow-students.

The following are the prizes awarded, with the names of those who gained them:—

Landscape painting.—Creswick Prize (30*l.*), John Henry Frederick Bacon. Painting of a figure from the life.—Silver

medal, 1st, Marcus Worsley Blackden; silver medal, 2nd, William T. Maud. Painting of a head from the life.—Silver medal, 1st, Stephen Briggs Carlill; silver medal, 2nd, Percy Short; *proxime accessit*, Ernest Appleby. Copy of an oil-painting.—Silver medal, 1st, Thomas Eyre Macklin; silver medal, 2nd, not awarded. Copy of a landscape.—Silver medal not awarded. Cartoon of a draped figure.—Silver medal and prize (25*l.*), Arthur George Walker. Design in monochrome for a figure picture.—Armitage Prizes, 1st (30*l.*) and bronze medal, Leonard Leslie Brooke; Armitage Prizes, 2nd (10*l.*), William T. Maud. Design for the decoration of a portion of a public building.—Prize (40*l.*), William Farran Littler. Drawing of a figure from the life.—Silver medal, 1st, Stephen Briggs Carlill; silver medal, 2nd, Harry Windsor Fry. Set of six drawings of a figure from the life.—1st prize (50*l.*), not awarded; 2nd prize (25*l.*), Stephen Briggs Carlill; 3rd prize (15*l.*), Sigismund C. H. Goetze; 4th prize (10*l.*), John Henry Frederick Bacon. Drawing of a head from the life.—Silver medal, 1st, Alice Maria Dicker; silver medal, 2nd, Ernest Spence. Drawing of a statue or group.—Silver medals, 1st and 2nd, no competition. Drawing of a statue or group.—Prize (10*l.*), Ella Brown. Prospective drawing in outline (open to painters and sculptors only).—Silver medal, no competition. Model of a design.—1st prize (30*l.*), Herbert Charles Nye; 2nd prize (10*l.*), Arthur George Walker.\* Set of three models of a figure from the life.—1st prize (50*l.*), Henry Charles Fehr; 2nd prize (20*l.*), John Wenlock Rollins. Model of a figure from the life.—Silver medal, 1st, Henry Charles Fehr; silver medal, 2nd, Charles John Allen. Restoration of a mutilated antique statue.—Silver medal, not awarded. Model of a statue or group.—Silver medal, 1st, Paul Raphael Montford; silver medal, 2nd,† Model of a statue or group. Prize (10*l.*), Anna Maria Gayton. Design in architecture.—Travelling studentship (60*l.*), Arthur Rutherford Jemmett. Set of architectural drawings.—Silver medal, 1st, Charles Spencer Haywood; silver medal, 2nd, not awarded. Set of architectural designs (upper school).—Prize (25*l.*), George William Nicolay. Set of drawings of an architectural design (lower school).—Prize (10*l.*), Francis Donkin Bedford. Prospective drawing in outline (open to architects only).—Silver medal, Amos Francis Faulkner.

The Landseer Scholarships in painting and sculpture, of 40*l.* a year each, tenable for two years, given for the best work done in the examination for passing into the second term of studentship, have been awarded—in painting, to Percy Short and Harold William Boutcher; in sculpture, to Thomas Richard Essex and William Henry Prosser.

The galleries containing the competition works were open to the public on Tuesday.

### LEEDS ARCHITECTURAL SOCIETY.

ON Monday evening a meeting of the Leeds and Yorkshire Architectural Society was held, Mr. H. Perkin in the chair. A paper on "Beauty in Colour and Form" was read by Mr. John Adam Heaton. He said that though now a Londoner, he was a native of Leeds, and appreciated the compliment paid him of being asked to bring the subject before the Society. With regard to beauty in colour, nature must be the text-book, though they must not suppose that the colouring of nature and of art could ever be thought of as identical. False colour and false form were mere exaggerations, distortions, excesses of good colour and good form. What was wanted, therefore, above all things was temperance. Nature was always temperate. He did not forget that she had produced malachite, the bell-gentian, the sunflower, but she had never dressed anything in seventeen yards of magenta silk with a pea-green bonnet. That had been left to mankind to do. Many tropical flowers were of great brilliancy, but it should be borne in mind how short a time the brilliancy lasted, and what a moderate area there was of this gorgeous colour measured against the greens and greys and browns of the surrounding vegetation. In the case of the gayest flowering plant ever seen, a careful examination would reveal the fact that what to the careless observer seemed a blaze of a certain tint was in reality a mass of subtle gradations. A gorgeous sunset lasted but a few minutes, and was generally small in area compared with the whole arc of the heavens; and it was so full of gradations that observers argued, after it was gone, whether it was most red or most yellow or most purple, orange, and grey. A student of colour soon found out that beauty of colour began with gradation—that the loveliness of graduated colour was so great that, relatively, level colour was not beautiful. But he also found that there was no such thing as level colour in nature—natural colour was always in a state of gradation. Nature teemed with grada-

\* Disqualified owing to having received the same prize before.

† Only one student entered for this competition.

tions; even when she played high she did so with a splendid moderation. He had been asked to sleep in a room where the four walls were distempered naked smalt blue. He declined, and would sooner have slept in the street. He had made careful studies of many beautiful coloured things—flowers, iridescence on pigeons' necks and shells, peacocks' feathers, fresh mackerel, and many other such things—and he never came upon a piece of brilliant colour where he was not bewildered and puzzled by the complex ways in which harmonious and even opposing colours interlaced and died into each other. Having learned a practical lesson from nature, we should fearlessly stick to it, giving away or burning everything at home—picture, wool-work, mat, wife's dress, drawing-room curtains—everything that did not obey the new-found rules, and in time we should come to appreciate the value of quiet, moderate, tertiary tints. Not a few people desired above all things that their surroundings should be in the highest taste, and who were nervously anxious and uneasy as to whether things would "go with" sundry other things. In gathering a posy one gathered flowers as a rule without any idea of what would "go with" each other, but simply the flowers that happened to be blooming and of the right dimensions for the proposed posy, and in ninety-nine times out of a hundred the flowers gathered "went with" each other delightfully. Why, then, should people be so nervous as to whether the proposed carpet would "go with" the proposed curtains. Clearly because the colour of one or both was bad—crude, violent, or without gradation—and because while the posy was well mingled with green and grey and neutral tints, the carpet and curtains were wholly or partially deficient in these. If one wanted to try whether this practically was so, let him buy or borrow a really fine old Persian carpet, which would probably contain blues and greens, reds and yellows; in fact, almost as many colours as the garden posy. He would find that the chances were enormously in favour of its looking well in any room in which he might throw it down, with an entire disregard of what might be already there. Let them take care that each colour in each article they bought was soft and graduated and free from crudity, and then they might set them all together and be happy. As gradation was the condition of beauty in colour, so curvature was the ground of all loveliness in form; but temperance, again, was the ruling power. A vote of thanks on the motion of Mr. W. H. Thorp, seconded by Mr. Cribb, was accorded to the lecturer.

### THE LINE OF FRONTAGE.

AMONG the Bills which were read a third time and passed in the House of Lords on the 6th inst., was one called "Public Health Acts Amendment (Buildings in Streets) Bill." The amendment deals with the much-debated question between urban authorities and property-owners as to the building line to be observed in the erection of property. Up to a recent period it was generally thought by the law advisers to the different urban authorities that the 156th section of the Public Health Act, 1875, applied to new as well as to old buildings, but in the case of *Williams v. the Wallasey Local Board*, heard in the Court of Queen's Bench, March 20, 1886, it was decided by Justices Mathew and A. L. Smith that the section as it was then framed did not apply to new buildings in course of erection on land never previously built on. In consequence of this decision builders could build their houses just as they pleased without any regard to the building line, and the urban authorities could not prevent them. The 156th section, which permitted this, was repealed last week, and in lieu thereof it has been enacted:—"That it shall not be lawful in any urban district, without the written consent of the urban authority, to erect or bring forward any house or building in any street, or any part of such house or building, beyond the front main wall of the house or building on either side thereof in the same street, nor to build any addition to any house or building beyond the front main wall of the house or building on either side of the same."

### The Recent Art Congress at Liverpool.

SIR,—The eloquent president, Sir Frederick Leighton, informed the listeners to his opening address that, although there is "a considerable and growing number of those in whom the sense and perception of beauty is astir and active; although vast sums from the public purse are annually devoted to the promotion of art; that schools of art multiply, almost swarm over the face of the land; that municipal bodies are not remiss on this score; that day by day efforts in this direction become

more marked and effectual; yet the sense of abstract beauty with the mass of our countrymen is dull, blunt, sluggish, and superficial; the æsthetic consciousness is not with them a living force, impelling them towards the beautiful or shocking them with the unsightly and the hideous."

Yet, Sir, is not this rather a rhetorical flourish than a logical and practical address? and will you pardon my boldness in venturing to raise the question, and to make a proposal founded thereupon?

It is admitted that there is much to be satisfied with that, as a nation, we pay a liberal tithe in the interest of art. History shows that the great art epochs were a work of time, that many generations of architects, sculptors, and painters succeeded one another before perfection was reached. We—and especially the artists—of this present year of grace, of this wonderful Victorian era, have certainly advantages that are without precedent. I boldly assert that, as Englishmen, we possess genius for the arts, for no country need despair that can show the works of a Reynolds, a Turner, a Constable, a Leighton, a Millais, a Poynter, and others too numerous to mention. An English school of painting of very high repute was established by Hogarth and Gainsborough. Can it be said that it has no worthy representatives at the present day, or that there is no appreciative public? Sir Frederick's confessions would go far to refute the charge.

I think, then, that what is really desired by our artists is a quickening of the pace towards an epoch—a modern epoch—of British art, and that they make a mistake in thinking that lecturing and discussing will bring about the widespread love of art for its own sake which in the past has always distinguished those brilliant periods when no edifice was considered complete without sculpture, mosaics, and frescoes, and the furniture of ordinary mansions was fit for a king's palace, and "there was nothing vulgar or hideous" even in a cottage. I beg, then, to offer the following plan for consideration.

Let an influential and well-selected deputation of men known for their love of art and of artists wait upon the Government to urge the necessity of a Council of Art being established for the following purposes amongst others:—  
1. The purchasing or otherwise distinguishing works of the highest art character annually produced. 2. The purchased works thus honoured to be placed with some public ceremony, in which the successful artists should be conspicuous, in a gallery to be built or set apart for them at South Kensington.

I venture to think that, if something of this kind could be done, enthusiasm in the community would be excited, critical knowledge would soon be improved, and that enlightened public feeling, which in past times created universal good taste, would at no distant time be established in this country; for we should possess constantly before our eyes lofty standards of excellence which all young artists would feel they must attain to. And in the meantime love of art in the general public, the "æsthetic consciousness" of the masses (for whom Sir Frederick pleads so eloquently) would be a daily growing result. At all events, it appears to have been under some such circumstances as these that art and artists flourished during the great epochs of art.—  
Yours faithfully,  
HENRY TRAVIS.

The Limes, South Streatham: Dec. 11.

### BUILDERS' BENEVOLENT INSTITUTION.

AN election of one pensioner on the funds of this Institution was held at Willis's Rooms, St. James's, on the 6th inst., Mr. T. G. Smith (vice-president) in the chair, in the unavoidable absence of the president, Mr. J. Howard Colls. There were three candidates for the one vacancy, viz. two men and one woman. The poll was open from two to five P.M. Shortly after the close of the poll, the scrutineers, Messrs. C. Russell and Thomas Stirling, announced the result of the polling to be as follows, viz.:—James Pickering, 19 Mantua Street, Clapham Junction, aged 62, builder (fifth application), 2,079 votes; Ann Winter, 47 Maygrove Road, Brondesbury, aged 63, widow of Benjamin Winter, builder (third application), 2,185 votes; and Henry Whimple, 12 Devonport Road, Shepherd's Bush, aged 71, builder and decorator (first application), 1,817 votes (including 30 votes in respect of former subscriptions). The successful candidate was therefore declared to be Ann Winter. Among the friends of the Institution (other than those already named) who took part in the proceedings were Messrs. Thomas Hall, R. Perkins, R. Richardson, F. Foxley, G. B. New, and J. T. Bolding. A vote of thanks to the Chairman closed the proceedings.

### CHURCH BUILDING AND RESTORATION.

St. Olave's, York.—The following report from Messrs. Demaine & Brierley was read at a late meeting of the parishioners:—In accordance with your instructions, we have pleasure in submitting for your consideration designs for im-

proving the nave and north aisle roofs of your church. As to the nave roof, we propose to take off the present lead and deal boarding, and to straighten and refix the rafters where necessary, to lay thereon oak boarding covered with felt, and to recast the old lead and relay it on deal battens and boarding. On the underside we suggest curved and moulded braces to the principals, finished with angels carrying emblems, a carved and moulded cornice against the wall, and carved pateræ on each of the intersections of the principals and purlins. The new work will be of dark oak, to match the old. The north aisle roof will be entirely new, of Stettin oak, and will consist of curved and moulded principals, intermediates, and purlins, and moulded rafters covered with oak boarding, and a carved and moulded cornice along the wall. The outer covering will be of strong lead, laid on deal battens and boarding. We estimate the cost of carrying out these works as follows:—Nave roof, 280*l.*; north aisle roof, 275*l.*; architects' commission, 30*l.*; contingencies, say 15*l.*; total, 600*l.* The work, when carried out, will greatly add to the beauty of the church. It was resolved, that subject to the sum of 500*l.* being promised by January 1, an order be given to the architects to proceed with the work.

**Ballynascreen.**—This church, which is in the diocese of Derry, was recently consecrated. The building of the church, which is now, with the exception of the tower, new throughout, was originally begun as but an improvement and remodelling of the old church. Hence, as it stands upon the lines of the old external walls, arises a somewhat unusual plan. The church now consists of a choir or chancel 35 feet long by 16 feet, with lateral aisles or transepts, and a short nave and south porch. The tower has been converted into a baptistery, and a lofty arch opened out on its western wall. To the south of the southern aisle is a lean-to aisle or ambulatory, which gives another entrance to the church. The vestry and its porch are placed in the north side. The chancel proper extends 10 feet eastward of the transept arches, and is entirely reserved for the offices of the Holy Communion, while the floor is extended westward as far as the central columns of the transepts and enclosed with a low stone curb, thus marking off the portion of the church set apart for the officiating ministers, according to the ancient arrangement of the *chorus cantorum* in the primitive church. The eastward windows, a triplet in the chancel, and a double in the south aisle, are filled with stained-glass by Messrs. Clayton & Bell, which are reproductions of windows in Christ Church, Dublin. The new church is heated by Grundy's system of hot fresh air. The church has been designed and carried out under the care of Mr. Thomas Drew, R.H.A., diocesan architect of Down, Connor, and Dromore. Mr. John McNally, of Cookstown, has been the contractor.

### GENERAL.

**Princess Christian** visited the Royal Female School of Art, Queen Square, on Monday, to open the new studio—erected under the supervision of Mr. Ernest Turner—and for which a sum of 300*l.* is sought from the supporters of the school.

**Lord Windsor** opened the winter session of the South Wales Art Society and Sketching Club on Saturday. It was announced that among the artists who had promised to contribute to the next Exhibition were Mr. Holman Hunt, Mr. Walter Crane, Mr. Onslow Ford, Mr. Arthur Gilbert, and Mr. Henry Moore.

**An Industrial Exhibition** is proposed to be held at Ipswich in 1890, at which prizes will be awarded.

**An Exhibition of Pictures** was opened at Kilmarnock on Tuesday, the number of works exhibited amounting to 867.

**Mr. Samuel Sanders**, of Trinity College, has offered to present six handsome stone urns or vases to be placed on the southern and eastern pediments of the Cambridge Senate House, in order to complete the original design of the architect.

**Mr. John Hutchison, R.S.A.**, has just finished in the clay a statue of the late Dr. Gregor, for erection in the town of Nairn. It is 8 feet high and will be cast in bronze. A realistic treatment is adopted for the figure.

**Mr. Muir**, one of the Glasgow city councillors, has purchased Mr. Pettie's picture, *Two Strings to Her Bow*, and presented it to the Municipal Art Gallery. It is the first gift from a member of the Council.

**Mr. Henri Lafort** has been elected for the third time as president of the Society of French Aquafortists.

**A Competition**, restricted to architects, with prizes of ten guineas and five guineas, is announced in the *Journal of Proceedings* of the Institute for the design of the vaulting over the entrance hall of a public building. Mr. Harvey, in order to prepare competitors for the above, announces that he will undertake to hold a new class at the Guilds Institute, South Kensington, on Tuesday evenings. The course will comprise

thirty lessons; fee, two and a half guineas. In order to enable arrangements to be made for beginning the lessons on January 1, intending pupils should send in their names at once to Mr. Lawrence Harvey, F.R.I.B.A., 10 Great Queen Street, Westminster.

**The Countess of Warwick** on Saturday distributed the prizes to the students of the School of Art and Warwick Art Class at Leamington.

**The Anglo-Australian Society of Artists** have elected the following members:—Sir J. E. Millais, Hon. R. W. Allan, R.W.S., W. Follen Bishop, F. Bourdillon, F. Bramley, E. F. Brewtnall, J. M. Bromley, Percy Craft, Ed. Harris, A. Hartley, E. Blair Leighton, W. S. Llewellyn, J. M. McIntosh, Frank Short, W. Christian Symons, Percy Thomas, Frank Walton, R.I., and Hugh Wilkinson.

**Mr. John Honeyman**, of Glasgow, has taken as a partner Mr. John Keppie, who was principal assistant to the late Mr. James Sellars. The business will be carried on under the title of John Honeyman & Keppie.

**Mr. William Dawes**, of Manchester, has been successful in the competition for the additions to the Buxton Hydropathic Establishment and Winter Residence.

**Mr. A. Addinell** delivered a lecture in the Art Museum, Nottingham, last Friday, upon "Athens and Athenian Art." He said that Greek art flourished under a democratic Government, when all worked for the benefit of the State. English art had flourished under a limited monarchy, where everybody worked for themselves. What was needed in England was less selfishness in regard to art.

**Alterations** have been made to the General Post Office, London, embracing the ventilation, the latest improved form of Messrs. Robert Boyle & Son's patent self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

**A Church** is to be built at Haydock, near St. Helens, towards the cost of which Mr. T. W. Legh, M.P., has promised a subscription of 2,000*l.* and a site.

**The Stained-glass Window** forming part of the Montrose memorial in St. Giles's, Edinburgh, has now been completed. It is entirely heraldic in design, and contains upwards of thirty coats-of-arms, representative of relatives and companions in arms of the great Marquis. The committee who have had the charge of the erection of the whole memorial have, in arranging the window, had the benefit of the advice of Sir Noel Paton, Mr. Burnett, Lyon King of Arms, and Mr. George Seton. The monument itself is designed by Dr. Rowand Anderson.

**A Free Library**, erected by the inhabitants as a memento of the Queen's Jubilee, has just been opened at Nantwich by Mr. Brunner, M.P.

**The Memorial-stone** of the new town-hall to be erected at Fulham was laid by the Rev. F. H. Fisher, the vicar and chairman of the vestry, on Monday.

**Mr. Stead**, of Bradford, has been appointed borough surveyor of Harrogate in place of Mr. E. W. Harry, appointed to Cambridge.

**The Foundation-stone** of a new eye and ear hospital which is being erected at Hereford, from the designs of Mr. E. Lingen Barker, has been laid.

**Mr. William Owen**, architect, has been placed by the Chancellor of the Duchy of Lancaster on the commission of the peace for the borough of Warrington.

**Mr. Charles Mason**, of Nottingham, has been appointed assistant borough surveyor at Leicester. There were 165 applicants.

**The Leeds Town Council** have decided to borrow 200,000*l.* for carrying out town improvements. The Council have also purchased the Coloured Cloth Hall at a cost of 66,000*l.*, and it is suggested that a new central post-office should be built on the site.

**A Cottage Hospital**, fully equipped, and containing six beds, has been presented to the borough of Carnarvon by Mr. John Jones, to commemorate his election for the third time to the Mayoralty.

**Mr. W. A. Eekersley** will read a paper on the "Oroya Railway in Peru" before the members of the Civil and Mechanical Engineers' Society, at the Westminster Palace Hotel on Wednesday next.

**Mr. W. E. Cox**, at a meeting of the Historic Society of Lancashire and Yorkshire on Thursday, read a paper entitled "Notes on some of the Antiquities of Garston, and an Attempt to recover the Plans and History of the early Church of St. Michael from its recently-discovered Remains."

**The City Lands Committee** of the Corporation have agreed, subject to the approval of the Home Secretary, to demolish Newgate Prison and the Central Criminal Court, and to erect upon the site a new Sessions' House, suitable to the modern requirements, as well as a fine row of shops.

### EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

### TENDERS ETC.

As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 p.m. on Thursdays.

Correspondents, when writing to notify an extension of time, or an alteration of the date of sending in Competitions or Contracts, are requested in their letter of advice to write at the head of the required change—"Contract Reporter to THE ARCHITECT."

### NOTICE TO THE PUBLIC.

By the Post Office arrangements THE ARCHITECT can now be sent to any part of the United Kingdom by an affixed Halfpenny stamp; hitherto the postage has very frequently been twopence per copy. The Publishers will be happy to forward, for 20s. per annum, post paid, THE ARCHITECT, to residents in towns and neighbourhoods to which there is no easy access by railway. Terms for the half-year, 10s.

Our readers are invited to address us on subjects of interest to themselves or the public. We shall be always ready to insert letters asking for a solution of any suitable questions of a professional or practical nature, and to receive replies to such inquiries.

### COMPETITIONS OPEN.

SOUTHAMPTON.—Feb. 1.—Designs are invited by the Executors of the late Mrs. H. Bellenden Sayer for the Erection of a Drinking Fountain. Messrs. Sharp, Harrison, Turner & Turner, Solicitors, Southampton.

YORK.—Feb. 16.—Designs, &c., are invited for the Erection of Courts of Justice and Police and Fire Brigade Stations. Premiums of £100, £50, and £25. Mr. George McGuire, Town Clerk, Blake Street, York.

## TRADE NOTES.

AT the last meeting of the Kilmarnock Town Council, plans for the Jubilee scheme for the erection of a bridge over the Irvine and a drive to Bellfield were considered, and that of Mr. Tait, Forth Bridge Works, was adopted, the premium of 10 guineas being awarded. The entire scheme is expected to cost about 2,500/, provided partly by rates and partly by public subscription.

THE new bridge between Glasgow and Hillhead, for which tenders are now being received, and which is to cross the Kelvin at Great Western Road, will be a handsome structure of granite, with iron arches. It will be 60 feet broad, or 20 feet wider than the present bridge. The work of reconstruction will be commenced in February next.

THE Oldbury Local Board have approved of a report of the Public Buildings Committee recommending the Board to purchase the freehold reversion in the land upon which the Public Hall stands, and the land adjoining, upon which it is proposed to erect the public buildings, containing 967 square yards, from the Oldbury charity trustees, at a cost of 400/. Also that Messrs. Wood & Kendrick, architects, of West Bromwich, should be requested to submit plans and estimates of the work for the proposed public buildings.

AT a meeting of the Evesham Rural Sanitary Authority on Monday, tenders for the supply of pipes for Wickhamford and Badsey Waterworks were opened, and that of Messrs. Firmstone Brothers, of Stourbridge, accepted, at the following prices:—3 in. pipes, 4/ 3s. 6d. per ton; 2 in., 4/ 3s. 9d. per ton; special castings (about 17 cwt.), 7/ 15s.

AT the monthly meeting of the Failsworth Local Board, plans of the proposed sewage works were submitted by Messrs. Lomax & Lomax, engineers, of Bolton, the estimated cost being 14,620/. Mr. C. J. Lomax, of the above firm, was appointed surveyor to the Board for a period of twelve months.

THE suggestions by the Local Government Board's architect of alterations in the plans of the proposed new cottage homes at Wednesfield have been adopted by the Wolverhampton Poor Law Guardians. This reduces the cost by 120/.

AT a meeting of the Ludlow Town Council a letter was read from Mr. Price, the contractor for the new Market Hall, asking the Council to allow him 50/ for Ruabon bricks for the facing of the new Market Hall, as he was unable to get the quantity

of pressed bricks locally, and he was anxious to push the building forward. If the Council allowed the 50/, he would still be at a loss of 35/ himself. It was decided that the Council ask the Market Hall Committee to grant the 50/., the money to come out of the Jubilee Fund.

AT Carlisle Mr. McKie, the city surveyor, has prepared a report for the consideration of the authorities and the citizens generally, upon the necessity for an extension of the main out-fall sewers and storm outlets of Carlisle, at an estimated cost of about 13,000/.

MESSRS. STEELE & WOOD, of Stoke-on-Trent, have just issued a sheet of designs, chromolithographed in numerous colours, of painted tiles for stoves, hearths, dados, pilasters, &c. Most of the sketches are well executed and very artistic.

THE ninth Architectural and Building Trades' Exhibition will be opened at the Royal Agricultural Hall, London, N., on Monday, April 1, 1889, under the management of Mr. Philip Shrapnel, of 20 Bucklersbury, London, E.C.

IT is stated that the Glasgow Corporation Street Improvement Trust has purchased the Gaelic Free Church, situated at the corner of Gordon and Hope Streets, at a cost of 31,000/., for the purposes of street improvements.

THE Honorary Freedom and Livery of the Worshipful Company of Turners of London has been conferred upon Mr. David Kirkaldy, M.Inst.C.E., "in recognition of his valuable services to Metallurgists, Turners, and all branches of Engineering, by his system of machinery and inventions for testing the strength and other properties of every variety of material used in the constructive arts."

WE are requested to state that Messrs. Keller Bros., of Hopton Wood Quarries, supplied the stone for the base of the Gordon Memorial.

A LINE of gas-piping has been completed at Pittsburg, Pa. The line is formed of 22,700 feet of cast-iron pipe and 400 feet of wrought-iron pipe, the inside diameter of the pipe being 36 inches. The cast-iron pipe weighs 485 lbs. per foot, and is 1 1/4 inches thick; the wrought-iron pipe is 3/4-inch thick, and weighs 190 lbs. per foot. The former has lead and asphaltum joints, with double escapes; the latter has an asbestos flange joint. All caulking is done from the inside of the pipe, so that the pressure of the gas will only serve to make the joint tighter. The pipe, when tested at the works, stood 300 lbs. pressure, and 80 lbs. pressure when laid.

ELSTOW, near Bedford, well known as the birthplace of Bunyan, has just had its church restored under the care of Mr. T. J. Jackson, architect, and a handsome clock has been erected by Messrs. John Smith & Sons, Derby. The clock is fitted with all latest improvements. All the main wheels are of the best gun-metal, with their teeth cut from the solid, so as to be perfectly accurate and smooth. The main frame is arranged so that any separate part may be removed without interfering with the remainder, and steel wire ropes carry the weights. Messrs. Smith & Sons guarantee the clock to go with very great accuracy, and to form a standard of timekeeping for the place. The clocks at Wootton and Goldington, near Elstow, were also made by the same firm.

THE London Street Board School, Edinburgh, is warmed and ventilated throughout by means of Shorland's patent Manchester grates, supplied by Mr. E. H. Shorland, of Manchester and London.

A SUGGESTION for the construction of a deep-water dock at Workington is under consideration. The construction of a deep-water dock has also been proposed for Harrington. The Workington Town Council intend to try and induce the promoters of the scheme to co-operate with Workington.

#### REGISTRATION OF PLUMBERS.

AT a public meeting in connection with the registering of plumbers held in the Carlisle town-hall the Mayor presided, supported by Canon Ware, Mr. Crowder, Dr. Barnes, Dr. Lockie, Mr. Richard Forster, town clerk, Mr. L. H. Armour, secretary to the District Council for the North of England, and others.

Mr. Hepworth, C.E., secretary of the local Association affiliated with the District Council at Newcastle, read a letter from Mr. William Brown, Medical Officer of Health for Carlisle, who said:—"While doctors and pharmaceutical chemists are subjected to the most searching tests as to their fitness for their respective callings, plumbers, who, from the very nature of their work, are much more potent for harm, are allowed to practise their craft free from fear of exposure, without any tested qualification whatever. I maintain that a plumber ought to be not only instructed in the *technique* of his handicraft, but ought to have forcible mental

pictures presented to him, illustrating the disastrous consequences to which his incapacity or neglect may give rise. Such instruction would have a powerful influence in preventing the deplorable prevalence of wrong and imperfect workmanship, which, I believe, results more from want of special knowledge than indolence on the part of those who perform it."

The Mayor said that there was some want of technical education in the art of plumbing. We were all much in the hands of plumbers, and it might be taken as a sign of the interest in the trade, that there were so many doctors present. The object of the meeting, however, was to see if they could not pay rather less to the doctors and rather more to the plumbers. Plumbing was different from most other trades, and there was a responsibility, dignity and skill required in the art of plumbing which made it second to no trade in the country. The Prince of Wales, after a certain illness, declared that if he had not been Prince of Wales he would have liked to be a plumber. The Plumbers' Guild, one of the most ancient Guilds in London, intended to do all they could to help the plumbers of England and Scotland. He had been present at the recent banquet of the Guild when the master made a very interesting speech on plumbing and sanitation; but the real gist of the matter was that they had held examinations of plumbers all over England lately and only 30 per cent. had passed.

Mr. Armour, of Gateshead, alluding to the movement which the Guild had volunteered to support with its corporate funds, said that in early days plumber's work partook largely of a decorative character, but now it was more utilitarian. Sanitation had made wonderful strides, and the plumber of to-day should be a man who could not only bend lead but who knew how it should be put in when it was bent. He should have some knowledge of chemistry, of hydraulics, and a great many other things, and it was to induce men to acquire the necessary qualifications that registration had been established. For the younger members of the trade the establishment of technical classes would be encouraged. One of the objects of the meeting was to elect representatives to the district council. The number for Carlisle would be nine, of whom three would be elected by the public, three by the master plumbers, and three by the operatives.

Mr. Crowder said he had attended in London last year, and had then heard sufficient to convince him of the importance of the work in hand.

Mr. C. J. Ferguson, architect, said that many of the

### SHORLAND'S PATENT COMBINATION OPEN FIRE-PLACE MANCHESTER STOVE, With Ascending or Descending Smoke Flue.

Made in Various Designs and Sizes. Thousands in Use.

SUCCESS GUARANTEED.

Very largely used in HOSPITAL WARDS, for which the draught arrangement, as now shown, is specially suited. As now being supplied throughout the Hospital Wards of the New Workhouse Infirmary, Birmingham, Oldham, &c., &c. Drawings, Prices, Testimonials, &c., on application.

MANY THOUSANDS IN USE.  
SUCCESS GUARANTEED.

By using the Patent Syphon Pipes the Heating Power of the MANCHESTER GRATE is increased, and the whole arrangement rendered simplicity itself.

The MANCHESTER GRATE combines great Radiating Power with Economy, and will burn Coke or any kind of fuel.

It delivers volumes of Pure Warm Air into the room in which it is fixed, and also into rooms above or adjoining, maintaining an equable and agreeable temperature throughout.

New Illustrated Catalogue Free on Application.

plumbers in Carlisle were registered workmen and were as anxious as any one could be that there should be no work ill done. It was exceedingly desirable that the registration of competent men should become general.

Dr. Barnes said that one of a doctor's functions was to prevent disease, and in that he would be helped by the present movement. Plumber's work, being covered up, was often scamped; but he believed it was imperfectly done from ignorance rather than design.

Mr. Armour mentioned there were about 4,000 plumbers registered throughout the country, and that architects were beginning to stipulate that only registered plumbers should be employed. He added that candidates for examination, who passed with honours, gained the Freedom of the Plumbers' Company.

The meeting then appointed representatives, and the Mayor distributed certificates granted by the Plumbers' Company to the following operatives of the city:—James Routledge, John Blair, John Routledge, John Graham, and William Brown.

#### WINDOW-CLEANING ACCIDENTS PREVENTED.

MR. W. YOULTON has invented a simple and inexpensive form of sash-fittings which, when applied to ordinary sliding sashes, enable the windows to open inwards for the cleaning or painting of the outsides without necessarily removing any flowers from the sills. The patent "Accident-preventing" sliding sash-fittings may be fixed in a few hours by an average handy man with only very slight interference with the wood-work and to any size window. Their general adoption will obviate the lamentable and frequent fatal accidents attending outside cleaning. The cleaning difficulty is solved in a remarkably simple and practicable manner, without additional draughts or detrimental strains. We recommend our readers to test the merits of the invention for themselves. Messrs. Lloyd & Co., 37 Great James Street, Bedford Row, W.C., are the sole agents at present, but arrangements are pending for the supply of the fittings in complete window sets by all iron-mongers. Mr. E. R. Robson, architect to the Education Department, has highly approved of the invention, and has adopted it for the Queen Anne's Mansions extension, of which he is architect, and also for the application of the fittings to all the windows in the existing building.

#### MESSRS. W. SCUPHAM & SONS.

AMONG the industrial establishments in the North lately visited by us is that of Messrs. W. Scupham & Sons, of Leeds, which was recently referred to in *The Architect*. Messrs. Scupham & Sons are timber and mahogany merchants, manufacturers of all kinds of moulded and cabinet work. The firm has lately issued a new illustrated catalogue under date of November 1, 1888. First are illustrated several mirrors in best English gold frames, varied in character and detail. Next come overmantels, so much in favour now, on the shelves and ledges of which nick-nacks and curios can find place. These are followed by gold mantel-glasses in differently designed frames. The black and overmantel glasses are characterised by taste in the samples illustrated. Looking-glasses for toilet purposes, cheval glasses, &c., are given in much variety, and then come sundry little specialties in the way of hang-up glasses, ovals, lavatory, and bath-room glass. Moulded cornice poles, straight and angular, and such like fittings, are also introduced, with articles of furniture of everyday kind. The wood mortice door furniture, such as knobs for door handles, are made in oak, ebony, and partridge wood—these are Longbottom's patent adjustable door furniture, of which Messrs. Scupham & Sons are the sole makers for the North. They have been used by Her Majesty's Board of Works, and also secured the gold medal at the Royal Jubilee Exhibition held at Saltaire last year. The firm have again lately extended their works, absorbing an adjoining estate, containing over 1,000 square yards, on which are four rooms 92 feet in length. In addition to the above, they have opened a commodious wharf near Crown Point Bridge, with a frontage to the river of 180 feet. These are fitted up with new and specially designed machinery for the sawing and working of timber. Overhead is a travelling crane, running the entire length of the yard and partly over the water, for landing logs from the boats and conveying them to the different tiers. In Saxton Lane are the drying-sheds, and at a distance of a minute's walk is the manufactory in Mill Street. In the turning-room the lathes are seen at work, square turning being also carried on extensively. In the picture-frame department are lengths of mouldings in gilt, walnut and gilt, black and gilt, bronze, silver, oak, maple, rosewood, &c. In an adjoining room is the machinery for converting them into frames. There is a picture store-room, and in another large room are men engaged in the

## Wilson's Patent Dioptrical Pavement Lights.

WILSON & CO. beg to call the attention of Architects and others to the superiority of Wilson's Patent Dioptrical Lenses for pavement and floor lights. These Lenses are constructed on strictly scientific principles, and have been approved by some of the highest authorities on Light. They are made of the Best English White Flint Glass of high refractive power, and transmit more light than any other form of Lens yet introduced. The reflecting surface being spherical, the rays of light are distributed in every direction.

Wilson's  
Patent Lenses  
for  
Floor Lights,  
Deck Lights,  
and  
Pavement  
Lights  
of every  
description.  
Sample Lenses  
on  
application.

Fig. 1 shows the ordinary prism or semi-prism, by receiving the rays on a plane reflecting surface, throws them forward at one angle only, in parallel lines close to the ceiling.

Fig. 2 represents the Patent Dioptrical Lens, and shows by comparison how the rays of light, striking on the curved inner surface, are reflected forward through the face of the lens in every direction, filling the whole angle of 90°, thus illuminating the apartment from floor to ceiling and from wall to wall.

From the above diagram it will be seen wherein consists the advantages claimed for Wilson's Patent Lenses. The objection to the semi-prism is that it reflects the light, as shown in Fig. 1, at such an angle as to be of little use, and more especially if the line of the ceiling is below the line of the pavement; then the value of the semi-prism as a light projector is entirely lost.

It will be seen also, on reference to the above diagrams, in Fig. 1 that the first row of semi-prisms obstructs the rays of light from each succeeding row, whereas in Fig. 2 the bulk of the rays of light are projected at such angles as to pass unobstructed into the room.

The correctness of these illustrations can be practically demonstrated to any architect desirous of testing them.

PRICE LISTS AND ESTIMATES ON APPLICATION TO

WILSON & CO., 117 Charterhouse Street, Charterhouse Square, London, E.C.

manufacture of toilet and mantel-glass frames. In the finishing-room the glass-cutters are at work, supplying the sizes required, the fitters putting them in the frames and adding the backs, after which they are passed on to the packers. In a workroom near by a number of women are busily engaged in polishing knobs, rings, spindles, cornice poles, &c.; others are finishing mouldings and different articles of furniture. A visit would hardly be complete without an inspection of the various stock and showrooms in the establishment. Mr. Scupham, senior, the founder of the business, is still the presiding genius of the establishment, besides being well known as a town councillor, and having taken great interest in all public affairs connected with the town for many years past.

#### AN ELECTRIC TRAVELLING CRANE.

THE application of electricity to the working of cranes has been increasing of late. Perhaps the first practical use of this agent for lifting purposes was the electric hoist of Dr. J. Hopkinson, exhibited at the Paris Electrical Exhibition of 1881. Since then it has been applied to hotel lifts and cranes, but not to any great extent. Quite recently, however, an electric crane of great power was described by Mr. W. Anderson at the Bath meeting of the British Association; and another large travelling crane, worked entirely by the electric current, has been introduced into the well-known timber-yard of Mr. Herrmann, at Limehouse. This crane has been adopted to avoid the insurance rates required for steam-cranes, which are obviously dangerous in a wood-yard. It has been designed by Messrs. R. E. Crompton & Co., of Chelmsford, and is found to do its duty very satisfactorily. Hydraulic power might have been used for the crane, but there was already an electric plant for lighting purposes on the premises, and hence electricity was adopted. The new crane runs on a tramway along the roof of the timber warehouse, and is used to raise the incoming logs of timber from the canal. An electric motor is attached to the frame of the crane, and geared with friction gearing of the Raworth type to a central shaft, which, by means of three levers and a foot-brake, performs the three operations of hoisting, slewing, and propelling the crane. The current is conveyed to the electric motor by two copper tubes, laid along the tramway, and taken off suitable contacts. In other respects the crane is of the ordinary build. The power is derived from an 18-unit Crompton

ton dynamo, which also supplies 300 incandescent lamps employed for lighting one of the factories. It gives a current having an electromotive force of 110 volts; and some 30 amperes are used to work the crane. It was specified that the crane should lift 15 cwt. as a *maximum* load, raise 10 cwt. at a speed of 80 feet per second, and slew at the same speed; but, as a matter of fact, it can lift 18 cwt., and in other respects the specification values have been improved upon.

#### CIRCUS BUILDING.

AN action has been decided in the Court of Session, Edinburgh, in which Mr. A. Stewart, builder, of Dundee, sought to recover 1,718*l.* 12*s.* 7*d.* from Mr. Newsome, the circus proprietor, as balance of an account for erection of a new circus in Edinburgh. From the evidence it appeared that Mr. Stewart was instructed in September or October last to build the circus, and it was represented to him that it was of great importance that it should be ready for occupation before the end of December or the New Year holiday season, and that he pressed on the building operations and had the circus so far completed as to get it licensed and ready for occupation within the desired time. The account for preparing plans, obtaining the authority of the Dean of Guild Court, and for erecting and furnishing the circus, amounted to 4,718*l.*; and he had received 2,000*l.* and a bond for 1,000*l.* over the property. The action was opposed on the ground that the work was performed under a contract by which it was a condition that the circus should be ready for occupation during the New Year holidays; that the price, including furnishings, was 2,700*l.*; that the 300*l.* over that sum which had been paid amply covered any additions or alterations; and, besides, that any addition or alterations were made on the builder's own responsibility and without instructions.

According to Mr. Newsome, his circus in Nicholson Street was burned down in September 1887, and Mr. Stewart, who was then employed by him to build a circus at Bradford, applied for the job of rebuilding the Edinburgh one. He agreed to give him the work of rebuilding it upon a plan similar to that of the Bradford one, and Mr. Stewart undertook to have the necessary plans prepared for the Dean of Guild Court, and to construct the building in accordance therewith, including the necessary fixtures and decorations, in time for the holiday season, for 2,000*l.* Plans were submitted to the Dean of Guild

# FIRE! FIRE! FIRE!

## GRIFFITHS' "PYRODENE" FIREPROOFING LIQUID

(NON-POISONOUS).

Transparent Liquid for Rendering Woodwork Uninflammable,

Without altering its appearance, and where Painting is not desired, such as Wooden Fittings in Exhibitions, Churches, Pews, Matchboarding, Theatre Scenes, Wooden Stairs, Joists, Beams, Floors, Factories, Stables, Mills, &c., in fact, Structures of an inflammable nature of all descriptions. Acts as a priming for new Woodwork for Paint or Varnish. Also for rendering Theatrical and Ball Dresses, Curtains, Paper, Felt, Canvas, &c., perfectly inflammable.

Griffiths' Liquid penetrates the pores of the wood. It lasts as long as the wood itself. It prevents Dry Rot and decay in house timbers. It does not crack, peel, or rub off.

It is perfectly innocuous and free from smell. It will keep any length of time. Any one can apply it. One gallon will cover double that of any other priming.

AND

All Woodwork in new houses should be fireproofed with this liquid, the cost is so trifling in comparison with the preservation of the timber and freedom from risk of fire. If work is desired to be painted afterwards, Griffiths' Pyrodene Paint is best for the purpose.

## GRIFFITHS' "PYRODENE" FIREPROOF PAINT.

READY FOR USE.

NON-POISONOUS.

ALL COLOURS.

This Paint is manufactured for preservative and decorative purposes equally as for its FIRE-RESISTING qualities. The Fireproof Paint and Fireproofing Liquid is used at some of the principal Theatres in the United Kingdom.

#### RECENT TESTIMONIALS.

From Messrs. MAXWELL & TUKE, Architects, 29 Princess Street, Manchester: December 28, 1887.

DEAR SIR.—We used your Paints in nearly the whole of the works for the Royal Jubilee Exhibition, and with very satisfactory results.

Yours truly, MAXWELL & TUKE.

To Messrs. Griffiths Bros. & Co., Dashwood House, London, E.C.

From S. O. LOWE & SON, House Decorators, 33 Cavendish Street, Stretford Road, All Saints, Manchester: November 22, 1887.

DEAR SIR.—In reply to your inquiry, we, as one of the contractors for the painting Manchester Jubilee Exhibition, which closed on the 10th of this month, have pleasure in stating that both your "Aqual" Paint, and also your "Pyrodene" Fireproof Paint, have given great satisfaction. We found them work easily with a covering power of from 30 to 40 per cent. over ordinary paint. Although applied during intense frost, and having been subjected to an almost tropical summer, followed by the drenching rains of this autumn, they are as fresh in colour and have as firm a grip as when applied, and appear quite unaffected by the nine months' exposure. We consider them, therefore, well adapted for all work in any climate.—Yours truly, S. O. LOWE & SON.

CHEAPER AND MORE DURABLE THAN ORDINARY PAINT.

GRIFFITHS' "PYRODENE" FIREPROOFING COMPANY, Limited,  
4 & 5 DASHWOOD HOUSE, NEW BROAD STREET, E.C., LONDON.

Court on October 27, but they were not passed till November 17, and that on certain conditions which were agreed to by plaintiff on his own responsibility without consulting him; and during the progress of the work plaintiff never intimated any additions. Mr. Stewart intimated on November 8 that he had made three plans, so as to suit the Dean of Guild Court, the Surveyor and Firemaster, and adjoining proprietors, and that he would require 2,500*l.* To this Mr. Newsome replied that he would give 2,700*l.* if finished in time for the holidays; and this sum and more has been paid, and he does not admit any extras. In answer, Mr. Stewart denied a contract for 2,200*l.*, and said that the character of the building was entirely changed after the 2,200*l.* was referred to, and that the change was very much to increase the expense. Both the public authorities and neighbouring proprietors insisted on these changes, which involved among other things the substitution of iron for wood, and the providing of additional exits and other precautions for the cases of fire occurring. The defendant was aware of these matters at the time, and that it would not be possible to reconstruct the buildings without expending much more than 2,200*l.* Defendant, after the plans had been prepared, instructed plaintiff that he wished the building to be such that it might be used as a music hall as well as a circus, and this added largely to the cost; and it was quite understood by all parties that the cost of the work so altered would be much above 2,700*l.*, and that plaintiff was to receive much more.

Lord Fraser, in giving judgment, said the question was whether the plaintiff contracted to build a circus for the sum of 2,700*l.*, and if he did not do so what sum was due for building it. The main difficulty arose from the discordant evidence of two persons, who he believed honestly intended to tell the truth according to the best of their recollection. The pursuer and Mrs. Newsome were hopelessly at variance as to a conversation which they had at Bradford as to the conditions on which the circus was to be built. Evidently they had not understood each other. Their letters and telegrams showed that they both laboured under difficulties of grammar and spelling, and it was evident that they did not express themselves with that precision which the circumstances required. Mrs. Newsome wanted the circus built speedily and cheaply, and the plaintiff said he would do his utmost to oblige her, and this was translated by her to mean he would build the circus for 2,700*l.*, a sum that had been named under totally different conditions from those under which the circus was actually built. Mrs. Newsome was anxious to have the circus opened by the New

Year, and plaintiff was anxious to have it completed, and put much energy into it. Objections were taken in the Dean of Guild Court, and new plans had to be got. As the burgh engineer said, there had been a kind of panic owing to the Exeter disaster a short time before, and more was required than would otherwise have been necessary. The rejection of the plans of November 10, his lordship said, brought matters to a crisis. Plaintiff went to Bradford, and, according to his evidence, he told defendant that the building could not be built for 2,700*l.* or 3,000*l.*, and the defendant agreed to pay whatever sum was necessary to build the circus by the New Year. On the other hand, Mrs. Newsome said that no agreement was come to, and there was no conversation about the price. The Court must decide between these contradictory statements. The Lord-Ordinary could not hold that there was a contract to build the circus for a specific sum as it was ultimately built. The building, according to one witness, was the quickest job he ever saw done; and he had been 50 years in business. Pressed by Mrs. Newsome to enable her to earn 1,000*l.* during the New Year holidays, which she described as their harvest, the plaintiff hurried on his operations without making those prudent arrangements with sub-contractors which he would have made if he had been acting under a specific contract. Plaintiff, must, therefore, be paid for the work and labour done and the material supplied, and the only course was to see what was a reasonable sum. Plaintiff had been paid 3,000*l.*, and claimed in all 4,718*l.* 12*s.* 7*d.* Now, if the defendant paid that sum he would get value for the money; the circus had been leased for three years at a rent of 1,300*l.* a year, and that was an excellent return. The building being fireproof it could be insured at a reasonable rate. His Lordship quoted the evidence of Mr. Barton, a professional witness, who stated that plaintiff's prices were reasonable, and seemed to be very fair, taking into consideration the short time in which the work had to be done. The building was up to the price charged; and the result was that he must give decree for the sum sued for, with expenses.

ROYAL PRINCESS'S THEATRE, LONDON.—The Christmas bill of this theatre will include the production at daily matinees, except Saturday, of "Oliver Twist," in which drama Miss Grace Hawthorne will appear as Nancy Sykes. These matinees will commence on Monday, 24th inst. "Hands Across the Sea" continues in the evening bill.

WORKS:

FIFTEENTH YEAR OF PUBLICATION. NOW READY.

## "THE ARCHITECT'S DIARY" FOR 1889.

Specially prepared for the use of ARCHITECTS, SURVEYORS, and ENGINEERS.

These Publications contain not only the usual Diary, ruled and printed to a particular form, specially adapted for professional use, but, in addition, an Index, a Note-Book, a Rent and Insurance Register, a Cash Book, and a Ledger, with all the usual diary information, and much special matter referring to the various Architects' and Engineers' Associations; a digest of all the Acts passed last Session; contain also cases decided in the Superior Courts of Justice during the legal year, from November 1887 to August 1888 of interest to the Profession; complete list of Metropolitan Surveyors and Districts, with Official and Private Address; Alphabetical Index to the Practical Statutes, Stamp Duties &c., the whole forming in ONE VOLUME A COMPLETE SET OF BOOKS for the YEAR. The Editions are—

No. 12.—One page to a day, size 8½ in. by 5 in., cloth, gilt, 4/6. No. 13.—Two pages a day, size 8½ in. by 5 in., cloth, gilt, 5/6.

## "THE BUILDER'S DIARY" FOR 1889.

Specially prepared for the use of BUILDERS and CONTRACTORS.

No. 11.—Two days on a page, ruled and printed to a special pattern; also contains Bill Register, Note Book, Rent, Insurance, and Mortgage Register, Cash Book, Ledger, and 130 pages of Tables of great value to all engaged in the Building Trade, in all 460 pages, size 8½ by 5, bound, whole cloth, gilt. Indexed, and paged to end of Diary. Price 4*s.* 6*d.*

"For use in the office of Architects and Builders they are better fitted than any diaries with which we are acquainted."—*The Architect.*

"Messrs. Hudson & Kearns's Diaries need no recommendation save a trial."—*The British Architect.*

"The novel and valuable feature of these Diaries is that each volume forms in itself a complete set of books for the year."—*The Builder.*

"We have used them ourselves throughout the year with much satisfaction, and are glad now to draw attention to the new batch sent us."—*The Building News.*

"The Diaries published by Messrs. Hudson & Kearns are quite unrivalled for convenience and comprehensiveness."—*Building World.*

"These Diaries may be said to have become the Diaries for the professions for which they are issued."—*Illustrated Carpenter and Builder.*

Sole Publishers, HUDSON & KEARNS, 83 Southwark Street, London.

## CITY OF LONDON COLLEGE.

ON Thursday, the 6th inst., a visit of the Science Society of this college to the Millwall Docks was arranged by Mr. Henry Adams, M.Inst.C.E., who accompanied the members. Mr. F. E. Duckham, the engineer to the Dock Company, met the party at the railway station, and was most assiduous in showing and explaining the many interesting details with which the Dock abounds. Among the points noted were some economically built sheds with compound iron and wood roof trusses, and other very light galvanised roofs of 60 feet span. When first opened the Dock was fitted with fixed hydraulic cranes on the quay; these have been supplemented by portable hydraulic cranes, which are found much more convenient, and they have since been largely adopted elsewhere. The arrangement of the pipe mains was explained, and the method by which a breakage at any point could be shut off by means of stop-valves, so as to permit the machinery at other parts to continue working. Branches at intervals allow connection to be made with the portable cranes, and the telescopic pipes provided give a considerable range of movement. The grain machinery was next inspected, with the automatic weighing gear and self-emptying buckets, and Mr. Duckham's pneumatic apparatus for discharging mud from the dredger barges was seen in operation. Much interest was taken in the hydraulic engine-house and the various pumping apparatuses, which were fully explained to the visitors. To prevent damage to the engines an ingenious self-acting relief-valve is used, by which a large area is opened to allow the pressure-water to flow back into the tank when the accumulator reaches the top of its stroke, and the draught of water from the main is suddenly reduced. The graving dock was fortunately empty, so that its construction could be seen, together with the flat-sided caisson at its entrance, a large ship being on the blocks in course of scraping and painting; and the noted 75-ton shears, by Messrs. Day & Sumner, of Southampton, were observed with some interest, owing to that subject having been set for the home work of students in machine construction at the last May examination of the Science and Art Department. By the courtesy of Messrs. MacDougal, their extensive wood-fibre paper-making plant was next seen in operation, from the arrival of the spruce fir logs at one end to the packing of the bales of finished paper at the other. The whole of the processes were in full swing, but an intimation was given that the visit was considered to be "private and confidential."

Before separating, Mr. Adams proposed a vote of thanks to Mr. Duckham for his kindness in allowing the members to visit the Docks, and especially for the trouble he had taken to explain everything likely to interest them. Also to Messrs. MacDougal, as the members who were unable to accompany the party certainly missed a treat in the unexpected addition of their works to the programme. Mr. Duckham, in replying, said he had not shown half there was to be seen, and he would be happy to meet the Science Society again to show them the remainder. This offer was fully appreciated, as the swing and drawbridges, dock gates, capstans, &c., could not be inspected, owing to darkness setting in. After partaking of Mr. Duckham's hospitality, the members returned to town, "sad" that winter days should be so short, but decidedly "wiser" than they set out.

## ENGLISH TRADE WITH NORWAY.

THE report of Acting Consul-General Hearn on the trade of Norway in 1887 states that the most noteworthy fact, from a British point of view, is the elevation of Great Britain to the first place in the value of the imports, a position which has hitherto been held by Germany. Although the surplus over the imports from Germany is only 23,000*l.*, or 4 per cent. of the total imports, still, in all previous years the balance has been very much the other way; and, at a time when the trade of Germany is being pushed to its utmost, and the competition with England is so great, it is satisfactory to find that the trade of Great Britain with Norway more than holds its own. At the same time, the imports from Great Britain increased by 50,000*l.*, or 1 per cent. of the total imports over 1886; while the imports from Germany decreased by 172,000*l.*, or 2 per cent. of the total. With regard to the exports, Great Britain took 31,000*l.* more than in 1886, which was, however, a decrease of 7 per cent. on the total exports; while Germany took 55,000*l.* more than in 1886, an increase of 5 per cent. on the total exports. The total trade with Great Britain increased, therefore, by 81,300*l.*, or 3 per cent. of the total commerce, and that of Germany decreased by 116,000*l.*, or 1.1 per cent. of the total foreign trade of Norway. The value of metals imported in 1887 reached 537,000*l.*, of which 276,000*l.* falls on raw and half-worked metals, and 261,000*l.* on worked-up metals. Among the former are included 182,000*l.* for pig-iron, steel, bar-iron, and iron plates, of which 34,363 tons were imported, which is

rather more than the average of late years. The import of pig-iron was 12,791 tons, or much more than the average of the ten years 1876-1885, which was 9,996 tons. The amount of bar-iron imported has been steadily increasing, and exceeded in 1887 17,032 tons, against an average of 15,663 tons for 1881-1885. On the other hand, the 3,650 tons of iron-plates imported were considerably less than usual.

SPANISH EXHIBITION, 1889.

ALL matters have now been definitely settled for holding a Spanish Exhibition next year at Earl's Court, upon the site of the late Italian Exhibition, when the president will be the Duke of Wellington, Grandee of Spain, and the vice-president, Colonel G. T. North. The most elaborate preparations are being made, and some very important arrangements have been entered into by the authorities. The Industrial Section of the Exhibition will consist of a magnificent display of the various manufactures of Spain and her colonies, whereby the public will be enabled to form some idea of the latent resources of the Spanish peninsula. A special selection of paintings and sculpture by Spanish artists, and representative collections of articles from the chief centres of the Spanish industry, including laces, Cordova leather, Toledo steel, Damascene ware, &c., will be included. Many descriptions of products will also be on view, including the raw materials, food stuffs, minerals, &c.; and a great feature will be made of the costumes worn in the different provinces. Spanish streets, villages, and shops will be erected and peopled by the men and women from the different districts, in their picturesque dresses. The process of manufacturing cigars from the tobacco leaf up to the finished article will be made a strong feature of, and last, but not least, ample provision is being made for the Amusements Section, always keeping in view the nature of the Exhibition. There will be daily exhibitions of bull-fights, with one very strong point, viz., without the accompanying cruelty usually practised. A large number of bull-fighters and assistants have been engaged, and a herd of Andalusian bulls will be imported. It speaks volumes for the energy displayed by the promoters of this Exhibition that they have been able to arrange for the exhibition of these famed bulls, as we understand none have ever been allowed to be taken out of the country before.

It is needless to say that music will be thoroughly well

looked after, several bands being engaged, including Spanish regimental bands, the Estudiantina band of guitars, castagnets, &c., and a troupe of dancers will be provided, consisting of men and women in their native costumes. A regular series of evening concerts will also be given, and ten noted players of the attractive game "Pelota" have been specially engaged from the Basque provinces. There will also be members of the Civil Guards in their attractive dresses, barbers in Figaro dresses, bandits in their picturesque attire, and various other attractions. It is anticipated by the authorities that the Exhibition will be open to the public about the middle of April next.

SANITARY SOCIAL PROBLEMS IN GLASGOW.

A MEETING of the Philosophical Society of Glasgow was held on the 5th inst, when Mr. John Honeyman, president of the Sanitary and Social Economy section, delivered his opening address for the session. Some years ago, he said, a good deal of harm was done by the late Dr. Farr's want of discrimination in dealing with statistics, which he (Dr. Farr), held, proved that the rate of mortality depended on the density of population. This seemed to confirm the erroneous theory which lay at the root of our own city improvement scheme, and against which he (Mr. Honeyman), among others, protested at the time of its inception, namely, that the dispersion of the population over a wider area was the best means of securing the proper housing of the poor. This view was at once superficial and fallacious. It was superficial because it ignored the fact—recorded in the report of the Royal Commission on the Housing of the Working-classes—that the root of the evil was to be found in "the poverty of the poor." That was the depth below the surface which we must reach if we were in earnest; a depth so dark, so mysterious, so beset with difficulties as to bid the boldest pause. It was fallacious because it attributed to density of population a result due to concomitant but absolutely independent causes. There was, in fact, no necessary connection between density of population and a high death-rate. Dr. Russell brought them much nearer the truth when he showed them the connection between small houses and high death-rates, although, as Dr. Russell himself acknowledged, even this only brought them a step nearer the real causes of mortality in crowded districts—poverty, starvation, vice, disease, and foul air in overcrowded, badly-planned houses. Nothing was more certain to aggravate all the evils which they at present deplored

than the erection of dwellings for the working classes by the Corporation of Glasgow, and it was astonishing to him that shrewd business men, as the majority of the Town Council are, failed to apprehend the futility, and the danger as well, of attempting to banish inexorable economic laws to Saturn or anywhere else. They were not to be got rid of at pleasure, and when violated exacted the penalty surely and remorselessly. He had not a word to say against the buildings erected by the Corporation in the Saltmarket. He agreed with Dr. Russell in thinking them excellent of their kind. But some town councillors seemed to think that by the erection of these buildings they had done the ignorant architects and builders of Glasgow a good turn by showing them how to get up dwellings for the poor. Now, that was an absurd mistake. There was no difficulty in designing or building dwellings quite equal to these in every respect, but the plain fact was that no sane builder would do anything so foolish, even if he were in the lucky position of being able to borrow money at  $3\frac{1}{2}$  per cent. It might suit the Corporation to erect these buildings so as to occupy and bring back population to some of their vacant ground, but to the community, apart from its slight interest in the "common good," these buildings were absolutely of no use either as models or in any other way. Let them consider them a little—first, negatively—as old divines used to say—and, secondly, positively. Firstly, they are not dwellings for the poor. The Corporation, with all Dr. Russell's facts before them regarding the wretched condition of ticketed houses, their faulty arrangements, and lamentable death-rate, might have been better excused had they attempted to show by their building operations some practical way of meeting this gigantic evil. A model block, showing how this could be done in a way sufficiently remunerative to tempt builders to imitate it would have been of immense value, and could not have been objected to if the Corporation pledged themselves not to erect another. This would be more apparent when they considered, secondly, the positive aspect of their conduct. When the first block was erected it was to be a model, but, as they had seen, it turned out to be a model which no sane builder would dream of imitating, because it would not pay him to do so. In the face of that fact, the Corporation resolved to imitate it themselves, with no excuse except that they could make it pay sufficiently to satisfy them. It was evident that they thus entered directly into competition with the builder, in circumstances which put anything like fair competition out of the question. Now, unfair competition inevitably led to monopoly, and he knew nothing

which in the long run would prove more injurious to the working classes than a building monopoly. The Corporation were bound to consider not merely the immediate financial results to them, but also the consequences which must follow their driving the ordinary builder from the field, in the shape of scarcity of house accommodation and increased rents; and they might depend upon it that a continuance of their present policy would surely lead to these results. At the annual meeting of the Kyrle Society the Lord Provost made some eminently sensible remarks on this subject, and also on one-room houses, which he cordially endorsed. If the Corporation really desired to benefit the working classes in this matter, their simple and only safe course was to give up building definitely, and to sell their vacant ground at prices which ordinary builders could afford to pay. But a much wider and more difficult economic question was suggested by the lamentable condition of the poor in all great cities, and in the country as well. He meant the great and interesting question of the better distribution of wealth. Except in so far as it contributed to this result, the better distribution of land was a matter of altogether secondary importance; but it seemed to appeal more directly to the popular fancy and interested demagogues, and certain sections of the press had therefore made the most of it. We really needed, and the need became pressing, something more radical still, something which would affect every class of society, from the highest to the lowest, and every variety of industry and commerce, in the way of regulating the distribution of wealth so that it would conduce to the greatest good of the greatest number. But it was well that we should ever remember that it was vain to expect that anything of this kind had the slightest chance of success if it either violated economic laws or in any degree discouraged individual enterprise. It could never be if either of these conditions were violated, and yet he ventured to express the opinion that the accomplishment of this great means of ameliorating the condition of the poorer classes was not impracticable. The more he thought of it the more he felt convinced that they must deal with poverty, the root of all grinding "sweating" slavery, not by diminishing the chances of the unhappy victims getting any employment at all, but by increasing those chances by the combined means of a greater diffusion of money and enlightened public opinion. There was nothing inconsistent in a keen Conservative favouring a Radical change in this respect; at all events, he regarded the claims of our terribly down-trodden poor as paramount, and his complaint against his Radical

brethren in this case was, not that they went too far, but that they went astray, and belied their profession and their name by ignoring altogether fundamental principles. He need hardly point out that as they could not increase the wages of the poor by throwing difficulties in the way of their getting work, no more could they facilitate their better housing by providing them with dwellings which they could not afford to pay for. It was a strong conviction of this which had led him more than once to protest against the imposition of such restrictions on buildings as had tended to keep the land in Glasgow belonging to the Improvement Trust vacant, and hindered the erection of dwellings of the humblest class. They might be able to effect many improvements which cost nothing, and sanitary authorities in Glasgow and other large cities had done much commendable work in this way; but such interference must not be carried beyond the rigid limit he had indicated; it must not increase the cost of the dwelling, or we did our poor brethren far more harm than good. Under present social conditions, then, there were two things almost equally essential to the well-being of the poor—first, that they do not get better houses than they can afford to pay for at less than a remunerative rent; and, secondly, that nothing should be done by local authorities to diminish or hinder the supply of houses suitable to the circumstances of the poor, that is, so cheaply constructed that the poor can afford to pay remunerative rents for them. It seemed impossible to drive the economic fallacy out of some people's heads that they could burden landlords without burdening their tenants. He referred to a scheme adopted by Miss Octavia Hill, and said that if the Glasgow Kyrle Society adhered closely to that method they would succeed, but he feared they must aim at obtaining from their property more than 4 per cent. Miss Hill obtained 5 per cent. after paying all expenses, including the usual commission for factorage, and if that was possible in London there ought to be no difficulty about it here, and it would no doubt go far to insure the steady development of the greatly needed and most praiseworthy work. In conclusion, he referred to what had been called "the sewage problem," which had within the last few days been once more brought prominently before them by Mr. Young. Mr. Young's proposal was probably the best which had been suggested. It was in his opinion the best non-precipitation scheme, but he must not discuss it now. It did not come under their notice because they were the sanitary section, but entirely because they were the social economy section. It was, in short, purely an

economic problem. It was thirty years since, in a paper read before the Architectural Society, he endeavoured to convince his fellow-citizens of this same fact, but during all these years proofs of the fact have been accumulating. Notwithstanding the enormous increase in the quantity of sewage thrown into the river, the death-rate of the city had gradually fallen from something like 35 per 1,000 to the very satisfactory rate of 17. In view of these facts, it appeared to him to be perfectly absurd to say that the general health of the community was affected by the condition of the river. Why, then, should the citizens be asked to pay a large sum of money for its purification? Only one satisfactory answer to this was possible, viz., that the operation would be remunerative—that we would thereby turn our sewage to profitable account instead of wasting it. But how did the matter actually stand? According to this very reasonable and economical scheme of Mr. Young, the ratepayers of Glasgow would be saddled with an annual deficit of upwards of 44,000*l.* And who were the ratepayers? He need not remind them how large a proportion of the rates in Glasgow came out of the pockets of the working-classes. It was they who would have to pay the greater part of this sum, for which they would get absolutely nothing in return. In contrast with that result, only imagine what 44,000*l.* per annum might do for us if we left "the sewage problem" unsolved. Five years of it would solve several other problems in which the working-classes were very much interested indeed. They would give us a respectable library, a museum, a school of art, a technical college, and another park—substantial and permanent advantages, in the enjoyment of which the five years of heavy taxation would soon be forgotten. The economist—and especially the social economist—must be satisfied that he got full value for what he spent, and when a proposal to spend so large a sum as 44,000*l.* per annum was made, there should be no difficulty in stating categorically the benefits which were thereby to be obtained. Health was not one of these—what was? It could surely be specified and appraised. He had searched for it in vain through all that had been said or written on this subject. They would all, he dared say, like to see at Stockwell Bridge the salmon running up in the pellucid stream as of old, and the fisherman playing his craft at Glasgow Green; but nine-tenths of the ratepayers never saw the Clyde; and even now it was not the domestic sewage which kept the salmon out, nor had we by any means done all that was possible to prevent pollution.

On the motion of the President, a cordial vote of thanks to Mr. Honeyman for his address was agreed to.

## NOVELTIES FOR THE HOME.

MESSRS. GODFREY GILES & Co.'s cosy corner supplies a long-felt want in small rooms where there is a recess each side of the fireplace, or in large rooms where there is an awkward corner. The difficulty is always what to put there that will be useful and at the same time artistic. These cosy corners are, as the name implies, very cosy and comfortable, and form a delightful nook in any room for a quiet read or a friendly chat. They are fitted with spring-stuffed seats and cushioned backs, and are made up in an inexpensive but artistic cretonne, unless specially ordered to be finished in a more costly covering. Often for drawing-room work they are covered with silk plush or silk tapestry. For morning-rooms, smoking-rooms, or snuggeries they are covered with a heavier tapestry or an art serge, and for bedrooms they are usually covered with

wood—and above this is fitted a little shelf to hold plates, or china nick-nacks. This invention, besides being artistic and also most useful in the shape of a sofa or easy chair, is very ingenious, as the whole takes to pieces in a few moments, and can be folded and packed away in quite a small space, which makes it very portable and convenient for travelling, removing, or stowing away temporarily when the space it occupies is otherwise required. By unscrewing two screws and unfastening the hook the end is released, the seat folds in half, the back cushion is hinged in the angle and folds back to back, the top frame, to which is fastened the shelf, lifts off, and also folds back to back. These corner seats will also be found most useful to fit in the corner of a staircase-landing when the room in which they usually stand is required for a dance, and they will also be of much use for divans in fitting up smoking-rooms or snuggeries in the Oriental or other styles, the low price

cretonne, chintz, dimity, or any other suitable covering to correspond with the surrounding drapery of the room. The cosy corner from which our sketch is taken had all the visible wood-work painted and enamelled white, although they are made sometimes of hard wood and polished, such as mahogany, walnut, &c., or they can be ebonised, if desired, to correspond with the rest of furniture in the room. For large rooms, where the distance between the fireplace and the corner of the room is too great for one of these cosy corners to be fitted as shown in our illustration, they are made to stand in any suitable corner, and are fitted with two ornamental end standards instead of one, the additional one being fixed where the chimney breast is shown in sketch. The ornamental work above the back cushion is the Lincrusta work for which this firm is so celebrated, and is treated in the same manner as the woodwork—*i.e.* either enamelled or decorated to correspond with polished

placing them within the reach of any of our readers. We would strongly recommend any one to write for full particulars, or call at the Lincrusta showrooms, 19 Old Cavendish Street, Oxford Street, W., and see these novel and artistic pieces of furniture. Another advantage this article has is that people who have a country house as well as a town one, can, when moving from one to the other, pack up the cosy corner, and in as few minutes fit it up in the house into which they are moving.

## THE SALISBURY ESTATE IN THE STRAND.

THE mode of laying out the Salisbury Estate, off the Strand, which the Marquis of Salisbury was recently able to dispose of under the Settled Estates Act, has just been decided by the

new freeholders. The estate comprises the whole of Cecil Street and Salisbury Street, which will be entirely absorbed under the plans about to be carried out; also the low-lying land between the south ends of those streets and the gardens of the Thames Embankment. It appears that many rival schemes have been proposed for laying out the estate, but the idea of retaining the privacy of the property has found most favour. One of the schemes proposed the retaining of the streets and merely rebuilding the houses, but the one which has been adopted provides for dealing with the site as a cleared one. In carrying out the undertaking the general idea of the Adelphi and its substructures has been agreed upon as the principal feature of the scheme. A plateau level with the Strand, over the whole area of the site, will be first constructed, having beneath it, and forming the substructures of the buildings to be erected over, a storey about 35 feet high, entered on a level with the Embankment, and altogether distinct from the Strand level. The plateau over this is proposed to be laid out as a square, entered from the present Cecil and Salisbury Streets, and surrounded by the several buildings to be erected. This square will be altogether private, and closed by gates at the entrance from the Strand. At the southern end a theatre is to be erected, drawings for which are now before the Board of Works. There will also be an hotel, with entrances to it on both the Embankment levels, there being restaurant accommodation on the lower level of the hotel. Messrs. J. W. Hobbs & Co. are the purchasers of the freehold from the Marquis, and Messrs. Perry & Reid are the architects. They have already designed a palatial building of six storeys, which is to be erected on the plateau, having its frontage overlooking the river and the Embankment gardens.

## PATENTS.

*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]*

## APPLICATIONS FOR PATENTS.

17446. George Humphrey, for "Improvements in weather bars and thresholds for doorsteps." November 30, 1888.

17452. Frederick William Jones and Alfred Thomas, for "An improved blind-cord holder." November 30, 1888.

17457. Hildebrand Henry Oakes, for "Improved soap and sponge tray, to be used in connection with a bath." (Complete specification.) November 30, 1888.

17502. Samuel Fisher and William Edward Fisher, for "Telescoping or collapsing handle for doors, cupboards, safes, and windows." December 1, 1888.

17525. Burton Richard Phillipson, for "Improvements in the ventilation of drain and soil pipes." December 1, 1888.

17570. Jesse Carpenter, for "Improvements to sliding sash-windows." December 3, 1888.

17578. Samuel Augustine de Normanville, for "Improvements in taps, cocks, or valves." December 3, 1888.

17583. Julius Frederick Moore Pollock, for "Improvements in machinery for moulding and compressing blocks of coal-dust, clay, cement, or similar material, with or without agglomerates." December 3, 1888.

17609. John Brown, for "Improvements in apparatus employed in the manufacture of gas and for prevention of stoppages in pipes." December 3, 1888.

17612. Urban Armstrong Smith, for "The sewerage of districts, towns, and places," to be called "The Urban Smith siphon sewerage system." December 3, 1888.

17620. William Preston, Campbell Everden and Edward Taylor, for "Improvements in the means and modes of collecting the laths of venetian blinds." December 3, 1888.

17641. John Ogg, for "Improvements in cutting and dressing stone and other hard substances, and in apparatus therefor." December 4, 1888.

17654. Albert Green, for "A gulley for streets, or any purpose for which it can be used." December 4, 1888.

17730. Clarence William Crossley, for "Improvements in the arrangement of propellers or their equivalents, for use as fans, air-propellers, and similar apparatus, for moving air fluids and gases for ventilating and other purposes, and in the manner of revolving such apparatus." December 5, 1888.

17731. Joseph Edward Aykroyd, for "Improvements in, or appertaining to, the ash-pits of domestic fire-grates." December 5, 1888.

17739. Hermann Marx Cornelius, for "Improvements in lock or fastener." December 5, 1888.

17752. William Millar, for "Ventilating boarded floors where the outside ground or pavement is level with or above

# The Architect.

## THE WEEK

THE buildings on the Champ de Mars which are assigned to the section of the fine arts of the International are found to be inadequate for the number of works which will be exhibited. M. FORMIGÉ has prepared plans for additions, and no time must be lost about the works if the new galleries are to be ready for the pictures which are about to be sent to Paris.

IN selecting Messrs. SHANNON, PICKERING, and KENNINGTON as members, the Institute of Painters in Oil Colours have recognised three able artists. Unless he is spoiled by praise and patronage, Mr. SHANNON should be among our foremost portraitists. Mr. KENNINGTON has mainly painted as if art were a handmaiden to the Charity Organisation Society, but can hardly fail to find subjects which are better adapted for so much grace as he can impart. Mr. PICKERING may also be expected to justify the choice of his fellow-members.

THE late Mr. RICHARD REDGRAVE, R.A., could hardly be called one of the great masters, but his work during thirty years for the promotion of art training in England deserves to be remembered. When he helped FELIX SUMMERLY in making designs for all sorts of things he risked much, for the experiment was understood by no more than a few people, but he demonstrated that he knew something about what was then called "practical art." It was a recognition of that skill when he was asked to report upon Industrial Design, as it appeared in the contents of the Exhibition of 1851. When the Government took up the teaching of art on a large scale he was called in. There were few artists who would undertake co-operation with a dictator like HENRY COLE, but Mr. REDGRAVE worked harmoniously with him for a very long period. He was not a genial director of art schools, but he had the credit of impartiality, and the most distant school was treated by him in the same way as the Training School. He had fixed notions about the limits of art when applied to manufacture, but now they are not generally accepted as canons. As a figure-painter he preferred subjects like *The Governess*, but if he had kept to landscape, we fancy that his name as an artist would now stand higher.

THE election of the council of the Société Centrale des Architectes has taken place with the following result:—President—M. CHARLES GARNIER. Vice-Presidents—M. A. NORMAND, M. E. DE JOLY. Principal Secretary—M. EUG. MONNIER. Associate Secretary—M. ED. LOVIOT. Assistant Secretary—M. F. ROUX. Archiviste—M. G. RAULIN. Treasurer—M. SIMON GIRARD. Censors—M. BAILLY, M. DAUMET, M. ACH. HERMANT. Delegates to the Council—M. BARTHAUMEUX, M. P. WALLON, M. DESLIGNIÈRES, M. HÉRET, M. JULIEN BAYARD, M. GUADET, M. SÉDILLE, M. JACQUES HERMANT, M. BONNET, M. EUGÈNE SAINT-PÈRE. The forthcoming year is an important one, and a good choice has been made of architects who will be able to represent the profession before the crowds who will meet in Paris.

THE annual distribution of prizes in the West London School of Art took place last Friday, the 14th inst., at the school in Great Titchfield Street. Mr. G. A. THRUPP, the chairman of the committee, presided, and was supported by Mr. SEYMOUR LUCAS, A.R.A., and Mr. G. A. STOREY, A.R.A. Mr. SEYMOUR LUCAS, in distributing the prizes, commented on the exhibition of students' works which, on the whole, he considered much above the average quality of work done in such schools, and he gave the students some useful hints as to methods of treatment for future guidance. He also bore eloquent testimony to the capability of Mr. JOHN PARKER, the new head-master, as a teacher. Mr. STOREY read an interesting paper on "Meissonier," whose life and works he cited as an example of perfection in art attained by unremitting care and attention to every detail consistent with a true study of nature. The committee having recently secured the services of Mr. JOHN PARKER, R.W.S.,

as head-master, have made other changes in the teaching staff likely to materially develop the efficiency of the school in future. There are now separate life classes for male and female students, as well as a special class for the study of flower-painting from nature, under the direction of Miss LOUISA AUMONIER, whose work is well known to the frequenters of our principal galleries, while the class for design is most ably conducted by Mr. M. COULSON. The school is within five minutes' walk of Portland Road Station. The "Mence Smith" travelling studentship, value 50*l.* (given by a member of the Painters Stainers Company for "colour decoration," and open to all the Schools of Art in London), was gained by Mr. JAMES WEST, while Messrs. WM. WOOL-LAMS & Co.'s annual prize for the "best design for a wall-paper" was awarded to Miss AMY WOODALL.

THE winter session of the Munich Academy of Painting and Sculpture has commenced this week. There are 356 students in the classes. Bavaria is represented by 131, the remaining German states by 105, Austria and Hungary send 73, and the balance of 47 students may be credited to the rest of Europe and America. The students can be classified in another way. The life classes are attended by 121, the painting classes by 117, the sculpture classes by 56, and composition and engraving have 62 students. The Prince Regent has nominated several artists as honorary academicians. Among them are Mr. WHISTLER, M. DAGNAN-BOUVERET of Paris, Herr ANGELI, the Court portraitist, and Herr SEIDL, the architect.

THE scheme of the Commissioners of the Exhibition of 1851 for the erection of houses on the south side of the Albert Hall does not augur well for the Indian Section of the South Kensington Museum. The examples of Indian art are unworthily housed at present, but it is better to be in wooden sheds than suffer an eviction with no better prospect than damp cellars. Up to the present the authorities have not appreciated Indian art. To visit the museum in the India Office one had to undertake a climb to the top of the building, and a day's study in the Indian sheds is likely to be rewarded by a chill. More should have been done to enhance the interest of the objects by means of a suitable building. Owing to Mr. PURDON CLARKE'S zeal the defects of the wooden buildings were minimised, and we have not met an officer in a Government department who was more ready to impart his knowledge of the things around him. Thanks to him, people are thinking more about Indian art than formerly. It will be a disaster if a stop is put to the excellent work which, after years of neglect, is now being done in the Indian Section.

THE Scottish Court of Session has recognised the distinction between an action taken under common law by a workman against an employer for compensation for injury, and one taken under the Employers' Liability Act. The circumstances were novel. In 1885 a workman was injured by the collapse of scaffolding, and he sought 1,000*l.* damages from Messrs. MORRISON & MASON, the contractors. With the object of gaining a large sum the action was not taken under the Employers' Liability Act. The jury, however, awarded only 200*l.* and costs. The contractor appealed, but the verdict was not altered. The costs amounted to 510*l.* 8*s.* 1*d.* It was partly to avoid an expense of that kind that the Employers' Liability Act was passed, and we are surprised, considering the amount awarded, that a lower scale of charges was not recognised. Messrs. MORRISON & MASON were insured in the Scottish Employers' Liability and Accident Assurance Company. They applied to the company for payment of 710*l.* 8*s.* 1*d.* disbursed, but the company declined any liability as the action was not brought under the Employers' Liability Act, and the contractors had not been paying the extra premium which is demanded in order to provide for claims under the common law. In this case also judgment went against the contractors in the first instance, and it was confirmed on appeal. The case is instructive, for it shows what is sometimes forgotten, that the Employers' Liability Act does not do away with the old course for obtaining damages, which, indeed, offers advantages to men who are dilatory in making claims against an employer.

## PROVENCE AND THE RIVIERA.—II.\*

THE buildings in Mr. MACGIBBON'S book which represent the post-Classical period may be said to consist of churches and castles. There are few houses to be found which can be called ancient until we come to the chapters on San Remo, Monaco, and Taggia. But the importance in the eyes of the author of the above period is evident when we say that the greater part of the book and nine-tenths of the illustrations relate to Transition and Mediæval works.

As we remarked before, the love of what was Classic always lingered in the district of Provence. It is seen not only in churches which might be taken for late Roman, but in the treatment of details. The pointed arch was employed at an early date in the district, but Mr. MACGIBBON says "it was limited to the vaulting, the round arch being preferred for all the ornamental parts of the architecture, and it continued to be so employed till the thirteenth century." Taken as a whole, Roman work may be called severe in spite of the occasional exuberance of the ornament, and severity obtained a new lease of life through the influence of the Cistercians. St. BERNARD, who was one of the law-givers of the Order, was indifferent to everything which could give pleasure to any of the senses. He brought himself into such a condition that he would not permit his eyes or ears or tongue to perform the ordinary functions for which they were given to us. His panegyrist, FLECHIER, says that St. BERNARD only lived in spirit, that he saw things like a blind man, listened like one that was deaf, and took food as if he were deprived of taste. The only created things he seemed to care for were the beeches and oaks of the forest, which he called his preceptors and masters. To a man like St. BERNARD architecture became a danger, and if he lived in our time his favourite temple would be probably one of corrugated iron or pitched boards. It is not plain how men could believe that their souls were safe if they worshipped in a church with square piers, while round columns with capitals marked the broad way to destruction. Evidently that sort of feeling towards architecture was sufficiently strong to compel the abandonment of details which had grown familiar to the people of the South of France. But nature is not to be resisted for ever. The Cistercians themselves felt that allowance must be made for the weakness of humanity, and they also encouraged the imitation of the flowers of the field as a means towards the beautifying of churches. In course of time a new impulse was also given to the architecture by the rise of artists who could practise the art. On this subject Mr. MACGIBBON says:—

The monks, who had hitherto been the sole possessors of the requisite knowledge and practical skill, had, by their schools, and by the guilds of tradesmen which they had encouraged, sown the seeds which were now springing up in a form they had not looked for, and producing a crop of lay artists who were soon to leave their old masters behind. The monastery system of carrying on everything according to rule had long held architecture in bondage. Under the new impulse all conventional rules were abandoned, and the artists trusted to the inspiration of nature for their guidance. Hence it followed that, whether in planning, in construction, or in ornamentation, the forms so long reverently followed by the architects of the monasteries were speedily dropped by the lay artists of the town, and a new art sprang up with the most marvellous rapidity. To the new school of artists nothing which would naturally and logically suit their requirements came amiss. The round arch was the traditional form of the ecclesiastics, but, the lay architects of the North finding (as the builders of the South had long previously done) that the pointed arch was more flexible and amenable to their requirements, forthwith adopted it. This enabled them to overcome what had hitherto been the great difficulty with the round arch, viz. to erect intersecting vaults over spaces of any form, whether square or oblong, and at the same time to keep the apex of all the vaults at any desired height. The transverse arches and the wall arches being thus pointed soon led in the most natural manner to the window arches within the latter being also made in a pointed shape, so as to conform to the outline of the wall arch, and by an easy transition the pointed arch was soon adopted for all the wall openings as the most flexible and most in accordance with the spirit of the new style.

Everyone who turns over the pages in Mr. MACGIBBON'S book will be struck with the variety that appears among the churches. In Lyons and Vienne we see towers which are reminiscent of Italy. The church at Cruas seems trans-

planted from the Rhine district. St. Paul-trois Châteaux has pilasters, an arcade, and other details which "might be part of a Roman amphitheatre." The south porch of Ste Martha, Tarascon, has nook shafts with caps partly copied from the Corinthian and partly carved with Romanesque figures. The arch mouldings, too, "contain a curious mixture of Roman and Mediæval ornaments in the Classic egg combined with the Gothic dog-tooth enrichments." Cistercian severity is to be found in St. Trophime, Arles, but the ornate porch, with its frieze suggestive of the *Dies Ira*, its sculptured interspaces of the columns, and tympanum showing CHRIST with the Evangelistic symbols, is in a different style. Some see in it evidence of the reaction, and suppose it to have been erected at a later time than the nave, but Mr. MACGIBBON believes it to be "part of an older building which has been preserved in the reconstruction of the nave." In any case the difference between outside and inside is very remarkable. In a somewhat similar style is the triple porch of Saint Gilles, but it is a far finer example of the Provençal style. Les Saintes Maries presents an example of a church which could be used as a place of safety by the parishioners. Another is Saint Victor, Marseilles. The most remarkable example of a fortified church is, however, the cathedral of Béziers, a town which was left without inhabitants during one of the massacres in the crusades against the Albigenses. At Moronet is a Cistercian abbey church which seems to be little altered. In it "the piers of the nave are simply portions of a side wall set on square slabs as a base." St. Maximin possesses a church which, as a good specimen of Northern Gothic, seems out of place in the district; the west front, however, is incomplete. Trejus Cathedral is covered with round intersecting vaulting, with deep groins springing from massive square piers or interior buttresses. The octagonal baptistery, with columns of granite having white marble capitals, which are placed at the angles, is as interesting as the neighbouring church. At Trejus the cathedral, tower, cloisters, baptistery, and palace are all united, forming a fortified group. The apse is utilised. The interior is circular, but the exterior is only slightly rounded, "and is carried up to a considerable height as a tower of defence, and armed with an embattled parapet at the top, supported on bold corbels with machicolations between them." The cloisters have arcades of a much later construction; the coupled columns bear beautiful caps.

The little island of St. Honorat opposite Cannes is described by Mr. MACGIBBON as possessing "the most interesting series of buildings in the Riviera, combining, as it does, some features of the architecture of every period and style of Provençal art, whether ecclesiastical or civil." Among the buildings illustrated is the ancient Chapel Ste Trinité, which is plainly but solidly built, with a triapsal choir. Mr. MACGIBBON supposes it to be "a rude attempt to imitate the triapsal and domical forms originally used in the Early Christian architecture of the cemeteries at Rome, and afterwards more fully developed in the East." The doorway has a massive lintel that would do credit to a cyclopean structure. Further on, at Grasse, columns are seen in the cathedral which resemble Norman work. The vaulting has deep square groins springing from square caps. At Biot is a church which at one time must "have been interesting, for it belonged to the Templars in the thirteenth century, but it is modernised" into a commonplace Renaissance chapel. But to enumerate all the churches along the azure coast which Mr. MACGIBBON describes would need more space than can be afforded. One thing may be remarked, that there are no repetitions among the churches he selects; each has something characteristic, and the majority are interesting.

The castles compete with the churches in attracting the attention of the reader. In the same way as proximity to the Mediterranean favoured the introduction of new ideas in art, it facilitated also the attacks of pirates. It was necessary to be prepared for resistance. In no part of Europe are so many remains of fortified castles to be found, and what remains are picturesque. Some, as Avignon, are of great size, but the smallest would make a subject for an artist.

Mr. MACGIBBON has carefully studied the books of MERIMÉE, VIOLLET-LE-DUC, and LEUTHERIC, but he has been more self-reliant when describing the churches and fortresses. His book will be an invaluable companion for

\* *Architecture of Provence and the Riviera.* By David Macgibbon. Edinburgh: David Douglas.

visitors to the South of France and the Riviera, and it will also afford information concerning an important phase of architecture.

### SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.

AT the meeting of the Sheffield Society which was held last week, Mr. H. W. Brewer read a paper on "The Smaller Mediæval Municipal Buildings of Central Germany," which was illustrated by a fine collection of unique pencil and water-colour drawings. Mr. Brewer explained the origin and marvellous development of municipal institutions in Germany and the Low Countries during the Middle Ages. They suited the character and genius of the people, and were especially vigorous in the free towns and those under the sway of the Prince Bishops. Municipal life and character flourished throughout the German Fatherland at that period to an extent unknown elsewhere, and in its free and bracing atmosphere architecture and all the arts and crafts flourished. The lecturer proceeded to describe in detail the interesting Rathhauses or municipal halls of Wurzburg, Munster, Hildesheim, Ratisbon, and Prague; and those of a smaller and less known type, such as Rothenburg and Dettlebach. Referring to an exquisite sketch of the latter, he pointed it out as an example of the ingenuity and inventiveness of the old architects, who generally turned difficulties to advantage. This building, so to speak, stood on no ground at all, being partly over a street and a river, and there were many such examples of the utilisation of difficult town sites which were invaluable to the architect of to-day. He alluded to the interesting Rathhouse of Ochsenfurth, where the council chamber has the original tables and furniture of carved pine wood, and a unique bronze pint or measure now in daily use, and dating from the fourteenth century. He pointed to sketches of these interesting fittings, and concluded by relating a humorous story about the abuse of municipal institutions in modern Germany, especially in the smaller towns and villages, where red tape and officialism are rife.

Mr. C. Hadfield, in moving a vote of thanks, remarked that the drawings had the graceful touch, feeling, and accuracy of a Prout, and evidenced that the labours and researches of the lecturer had been a labour of love. The important question of new municipal buildings in Sheffield was within measurable distance, and he had every confidence that the municipal life and character of their old town to-day would be able to produce happy results if only the work was undertaken in the common sense, practical, and artistic spirit that characterised the buildings of the old German burghers. Mr. Hemsoll seconded, and a hearty vote of thanks was awarded to Mr. Brewer for his interesting paper.

### EDINBURGH ARCHITECTURAL ASSOCIATION.

THE paper read at the meeting on the 13th inst. was by Mr. Archibald C. Elliott, D.Sc., assistant to the Professor of Engineering in the Edinburgh University, being "Recent Departures on Electrical Engineering." The subject of artificial lighting, he remarked, belonged to the utilitarian rather than to the artistic side of the architect's business, and in his vocabulary was one of a set of three—lighting, warming, and ventilating—none of which had, unfortunately, hitherto received from him all the attention which was justly its due. Restricting the scope of the paper to the recently developed systems of distribution at high pressure from main generating stations, Dr. Elliott hastily glanced at the history of the subject, which, he stated, might be said to commence with the lighting in 1884 of several stations on the Metropolitan Railway by the system of Messrs. Gaulard & Gibbs. Until then, engineers had thought that there was no help for it but to let from 50 to 75 per cent. of the prime cost of an installation be sunk in copper mains; but on the new system the electrical energy was transmitted through comparatively light mains at enormous pressure—from 1,000 to 10,000 volts—and, by means of "transformers," placed at convenient points, was delivered to householders at the quite harmless but useful pressure of 50 to 100 volts. Dr. Elliott then showed how, in the modern transformer, the usually intractable property of self-induction turned itself to good account, and was the means of rendering the apparatus almost perfectly self-regulating. The efficiency of a transformer was rather difficult to measure; and that in some degree accounted for the distrust with which it was at one time regarded. The theory had, however, all along pointed to a high efficiency; and it might now be said with safety that the efficiency of a good transformer at full load was considerably over 90 per cent. In order to show the great advance which had been made, he had calculated the cost of a distributing main for 5,000 lamps, extending, say, from some distance west of St. Mary's Cathedral to somewhere beyond

St. Andrew Square, to be, on the old parallel system, 14,000*l.*; on the three-wire system, 10,500*l.*; and on the new high-pressure transformer system, 4,200*l.*; and, in addition to the saving in cost, the transformer system, he pointed out, had the advantage of a much more constant pressure in the mains. Mr. Ferranti, the engineer to the London Electric Supply Corporation, whose company at present worked the Grosvenor Gallery installation, had decided to use in the new Deptford installation, which would be without exception the largest in the world, no less a pressure than 10,000 volts. The expansion would be carried out in two stages—first, from 10,000 to 2,400 volts, and then from 2,400 down to 100 volts in the consumers' mains. On the advice of Sir William Thomson, Mr. Ferranti was going to use for the 10,000 volts mains a conductor of two concentric hollow copper tubes separated by an insulating compound. The outer tube would be at the potential of the earth, so that although the main might be transmitting energy at the rate of 5,000 horse-power it might be touched with impunity. Mr. Heaviside had shown that the copper near the axis of a conductor carrying alternating current was, owing to self-induction, much less effective than the outer part; and it would be interesting to see how far this conclusion was borne out practically at Deptford. Through the kindness of Mr. Ferranti an actual 2,400 volt transformer and some other apparatus for the Deptford installation were exhibited to the meeting.

### HOUSE PROPERTY IN GLASGOW.

AN ordinary meeting of the Architectural Section of the Glasgow Philosophical Society was held on Monday night in the Rooms, 207 Bath Street, Mr. James Thomson, president, in the chair. Mr. James Chalmers, architect, read a paper on "Some Considerations Affecting Unremunerative Property in Glasgow." Whether a property was remunerative or unremunerative depended, Mr. Chalmers said, on the return or the rate of interest it yielded on the money invested. The City Improvement Trust, in order to save a certain loss, combined with the pleasure of providing a few houses for the poor, were willing to consider a small interest as an ample recompense for their expenditure. But a distinction must be made between business and philanthropy. Property was remunerative or otherwise according as it returned an adequate or inadequate interest. Mr. Honeyman thought 5 per cent. a fair interest on the housing of the poor, and others considered 4 per cent. sufficient, holding that plenty of capital would be forthcoming at that rate. In the case of Mr. Goschen's conversion scheme, we found investors taking 2½ per cent. on first-class security, but this was only practicable on the part of Mr. Goschen because there was such an amount of money in the country seeking an investment of some kind. The question came to be this. If 3¼ per cent. was considered a fair remuneration on such securities as railways and Corporation stock, what was a fair amount on property rent? Clearly the difference in risk. That varied very much, and he found that corresponding periods had somehow occurred after intervals of ten years. These were made up of about three years of depression, three years of steady trade, and three years of excited trade, the last of these bringing on the depression again and creating panic and collapse. As a matter of fact, property was often remunerative or otherwise very much in sympathy with the divisions of these trade or credit cycles, and what they had to do was to try and find out the causes of them. Those who had experienced the results of the inflated period which terminated in the collapse of the City of Glasgow Bank should not find that very difficult to do. When it was believed that property was the investment of the future, speculators rushed into building operations, with the result that the supply exceeded the demand, and the investment became an unremunerative one. That was the case at the time of the building mania, 12 or 15 years ago, the result of which was that the public had no confidence in property as an investment. If property were bought when at its cheapest, and the investor could afford to hold it, he was sure to gain; but if bought at its dearest he was sure to lose, unless he could hold until another inflated time came. Regarding the houses inhabited by the poor, Mr. Chalmers said that if they were not remunerative it was because these slums had changed hands at an inflated value, and the present holders must be taking extraordinary means to retain a sufficient interest on this value. He thought that after allowing for taxes, repairs, and depreciation, the risk in this class of property should be amply covered by a return of 4 per cent. Referring again to the tenements erected by the Improvement Trust in Saltmarket, he said it seemed to be admitted on all hands that they were not dwellings for the poor. The rent the poor could afford was 7*s.* 6*d.* to 10*s.* per month, and as the rent charged was more than that they were valueless to the poor. He thought property was taxed too highly, and that all real property, or actual income, should be taxed as well as property.

## TESSERÆ.

## Generalising in Art.

SIR C. L. EASTLAKE.

IN representations which depart altogether from nature, and belong to the regions of poetry, those details are suppressed which would betray the convention of the idea. In very abstract representations of nature, also, all circumstances which would diminish the grandeur of the impression are omitted. There is evidently, then, a necessity for generalising in every branch of art; there is always much to be omitted, and the omission of useless or pernicious detail only makes the whole, the ruling idea, more impressive and distinct. In the imitation, therefore, of nature the great question is, What is the general character of the impression received? and next, What are its chief causes? If these are duly ascertained, the opposite circumstances which counteract the impression are easily detected and suppressed, or only hinted at. It is not uncommon to find persons who have the truest feeling for the poetry of a scene (and even artists are among them) who in imitating the same scene on paper or canvas make such things prominent as destroy the very feeling they experience. This translation of a feeling into picturesque analogous representations is an art of itself. There can be no doubt that our memory of nature is composed entirely of general ideas, and art must be generalised to meet this idea of beauty. The mere copying of nature in detail is not only objectionable, because it does not correspond with our impression of her, but it immediately suggests the feeling of its inferiority to nature, and the more so the closer it is. Thus an imitation so close as to produce illusion to the eye would be precisely that which would be considered defective, because whatever remains unaccomplished—sound, motion, &c.—would be felt to be wanting.

## The Pantheon, Rome.

VIOLET-LE-DUC.

What, in the Pantheon at Rome, is it that produces the most lively impression? It is that immense vault which derives all its decoration from its very structure; it is that single opening for light, 26 feet in diameter, perforated in its summit, through which the zenith is seen, and which throws upon the pavement of porphyry and granite a large circle of light. It is there that the genius of the Roman appears in full strength. So great is the elevation of this orifice above the floor, that its enormous opening scarcely affects the internal temperature. The most violent storms scarcely send down a breath of air on the head of a person standing beneath its orbit; and when it rains, the drops are seen falling perpendicularly down upon the pavement of the Rotunda, on which they describe a circle of wet. The cylinder of raindrops, falling from that height through the space of the building, renders sensible the immensity of that space. It is in conceptions like this that the Roman is really grand, because they are the outcome of his own genius, and because for their execution he borrows from no one, nor asks the aid of any artist whose nature is foreign to his own.

## Nero and the Burning of Rome.

G. H. LEWES.

There is no assignable motive which can point suspicion at Nero, and he happened to be absent from Rome when the fire broke out. The silly credulity which for centuries has accepted this story, with its mythical embellishment of Nero in mad exultation at the success of his wantonness fiddling above the burning ruins, is a striking example of what will pass as history. Suetonius gravely relates that some one having quoted a Greek verse, the meaning of which is, "After my death I care not if the world perish in flames," Nero exclaimed, "Nay, let it perish while I live." "And," adds the historian, "he acted accordingly; for, pretending to take offence at the ugliness of the old buildings and the narrowness of the streets he set the city on fire, and this was done so openly that several consulars found tow and torches in the houses of his attendants, but were afraid to meddle with them. He knocked down the walls of the granaries, which were of stone, in order that the flames might spread. The fire he beheld from a tower on the top of the villa of Mæcenas, and being hugely diverted with the splendours of the flames, he sang the 'Destruction of Troy' in the dress worn by him on the stage." Yet the people patiently submitted to be ruined, and thus openly mocked, not even wreaking their vengeance on the attendants! Suetonius in a previous chapter has recorded of Nero that he ordered piazzas to be erected before all the houses, great and small, in order that in case of fire there might be a commanding position for extinguishing the flames; and these piazzas were constructed at his expense, so little did he disregard the interests of his subjects. Tacitus, a graver writer, tells the story with less manifest fiction. He says that the fire was by some attri-

buted to accident, and by others to the wickedness of Nero, adding, "Nero at that time was at Antium, and only returned to Rome on the day when the flames approached his own palace, which he had built to join the palace of Augustus with the garden of Mæcenas. This palace and all the buildings around it were burned. To console the people, wandering and houseless, he opened the Campus Martius, and the monuments of Agrippa, as well as his own gardens. Here sheds were hastily constructed to shelter the poorest. Furniture was fetched from Ostia, and the price of corn was considerably reduced." Thus the public acts of Nero are not only those of one innocent of the imputed crime, but are those of an emperor really concerned for the misfortunes of his people. It is quite possible that such acts may have been mere hypocritical attempts to disarm suspicion; and if the crime were proven, or even probable, such an interpretation might pass. But what evidence, what probability is there, to justify such an accusation? The vague rumours of an exasperated people. How these arise, and how supremely they dispense with evidence, need not be told. Have we not in our own time known the famine in Ireland boldly assigned to the wrath of Heaven because the words *Defensor Fidei* accidentally were omitted in a new issue of silver coin? and this accusation proceeding, not from ignorant and turbulent mobs, but from the ignorant and bigoted "religious world," as it unjustifiably calls itself. Jurymen accustomed to deliver verdicts in cases brought by fire insurance offices must know the kind of evidence which they demand, before they believe that a fraudulent tradesman has set fire to his own premises. I ask them if they can see anything of this kind in the accusation against Nero? Without demanding the completeness of circumstantial evidence which would coerce their verdict against a living man, I simply ask whether there is any evidence against Nero? All that historians have produced has been given in the foregoing narrative; its value may now be estimated.

## Admission of Air to Rooms.

D. GALTON.

Air should be introduced and removed at those parts of the room where it would not cause a sensible draught. Air flowing against the body at, or even somewhat above, the temperature of the air of a room, will cause an inconvenient draught, from the fact that, as it removes the moisture of the body it causes evaporation or a sensation of cold. Air should never, as a rule, be introduced at or close to the floor-level. The openings would be liable to be fouled with sweepings and dirt. The air, unless very much above the temperature of the air of the room, would produce a sensation of cold to the feet. It may be regarded as an axiom in ventilating and warming that the feet should be kept warm and the head be kept cool. The orifices at which air is admitted should be above the level of the heads of persons occupying the room; the current of inflowing air should be directed towards the ceiling, and should either be as much subdivided as possible by means of numerous orifices, or be admitted through conical openings, with the smaller openings towards the outer air and the larger openings towards the room, by which means the air of the entering current is very rapidly dispersed. Air admitted near the ceiling very soon ceases to exist as a distinct current, and will be found at a very short distance from the inlet to have mingled with the general mass of the air, and to have attained the temperature of the room, partly owing to the larger mass of air in the room with which the inflowing current mingles, partly to the action of gravity in cases where the inflowing air is colder than the air in the room.

## Endurance of Storey Posts.

E. M. SHAW.

The contents of a building have undoubtedly much to do with its safety or danger; but, in estimating the whole risk, the materials of which the building is constructed must never be put out of consideration. Every building cannot be erected with brick columns and groined arches; but there is a vast range between these and the miserable cast-iron posts too commonly to be seen, many of which have been put in without having been tested for strength even at the ordinary temperature of the atmosphere, much less at that of a fire. The following illustration may be given of a fact well known to all firemen of experience, but seldom proved to demonstration for those not specially interested. A fire occurred in a warehouse of enormous proportions, and raged with great fury for five hours, at the end of which time it was extinguished, and a very large proportion of the building and its contents saved. The warehouse was constructed of brick walls; it had wooden floors, supported on wooden beams, which in their turn were carried on wooden storey-posts about 12 inches thick; and, although serious damage was done, not one portion of the heavy woodwork was destroyed. After the fire the proprietors allowed the chief of the fire brigade to remove one of the storey posts, with a section of the beams and other parts surrounding it above and below. This post had been subjected to

the full action of the fire during the whole of its duration, as already mentioned, or, making full allowance for everything, including the delay of the fire attacking the particular spot on which it stood, and the time at which the cooling process commenced, certainly not less than four and a half hours. As large quantities of water had been used, and it was probable that everything had been saturated, the wood was carefully dried before a strong fire until not a trace of moisture remained in it. It was then set on end in an open yard, exactly as it had stood in the warehouse, with the pedestal underneath, the cap above, and the beam across the cap; more than a ton of shavings, light wood, and heavy wood were placed round it, and after the whole heap was saturated with petroleum a light was applied to it; and, after this, large quantities of petroleum and turpentine were pumped on it. At the end of two and a half hours the post, beam, and other parts were withdrawn from the fire, and within a few minutes from the time at which they were withdrawn they ceased to burn. A few feet were then sawn off horizontally, at that part which had suffered most from the flames, and afterwards the same piece was split longitudinally with steel wedges, in order to examine its condition. The post was of pitch pine, about the most inflammable wood known, and yet after exposure for seven hours to fires, the fury of which could not be exceeded except in blast furnaces, it contained within it a quantity of perfectly uninjured and apparently fresh wood, probably capable of supporting the whole weight which the original post was designed to carry. Immediately after the saw-cut, and again after the cleaving with steel wedges, the centre was carefully examined and found to be just perceptibly warm to the touch, but nothing more, thus proving that the fibre in which the strength lay was quite uninjured.

#### First Steps in Painting.

T. EAKINS.

The brush is a more powerful and rapid tool than the point or stump. Very often, practically, before the student has had time to get his broadest masses of light and shade with either of these, he has forgotten what he is after. Charcoal would do better, but it is clumsy and rubs too easily for student's work. Still the main thing that the brush secures is, the instant grasp of the grand construction of a figure. There are no lines in nature, as was found out before. Fortuny exhibited his detestation of them; there are only form and colour. The least important, the most changeable, the most difficult thing to catch about a figure is the outline. The student drawing the outline of that model with a point is confused and lost if the model moves a hair-breadth; already the whole outline has been changed, and you notice how often he has had to rub out and correct; meantime he will get discouraged and disgusted long before he has made any sort of portrait of the man. Moreover, the outline is not the man; the grand construction is. Once that is got, the details follow naturally. And as the tendency of the point or stump is, I think, to reverse this order, I prefer the brush. I do not at all share the old fear that the beauties of colour will intoxicate the pupil and cause him to neglect the form. I have never known anything of that kind to happen, unless a student fancied he had mastered drawing before he began to paint. The first things to attend to in painting the model are movement and the general colour. The figure must balance, appear solid, and of the right weight. The movement once understood, every detail of the action will be an integral part of the main continuous action, and every detail of colour auxiliary to the main system of light and shade. The student should learn to block up his figure rapidly, and then to give to any part of it the highest finish without injuring its unity. To these ends I have not the slightest hesitation in calling the brush, and an immediate use of it, the best possible means.

#### The Object and Aim of Art.

G. W. F. HEGEL.

It is the object and aim of art to bring within the circle of our senses, perceptions, and emotions everything which has existence in the mind of man. Art should realise in us the well-known saying, "Nihil humani a me alienum puto." Its appointed aim is to awake and give vitality to all slumbering feelings, affections, and passions; to fill and expand the heart, and to make man, whether developed or undeveloped, feel in every fibre of his being all that human nature can endure, experience, and bring forth in her innermost and most secret recesses; all that has power to move and arouse the heart of man in its profoundest depths, manifold capabilities, and various phases; to garner up for our enjoyment whatever, in the exercise of thought and imagination, the mind discovers of high and intrinsic merit, the grandeur of the lofty, the eternal and the true, and present it to our feeling and contemplation. In like manner, to make pain and sorrow, and even vice and wrong, become clear to us; to bring the heart into immediate acquaintance with the awful and terrible, as well as with the

joyous and pleasurable; and lastly, to lead the fancy to hover gently, dreamily on the wing of imagination, and entice her to revel in the seductive witchery of its voluptuous emotion and contemplation. Art should employ this manifold richness of its subject-matter to supply on the one hand the deficiencies of our actual experience of external life, and on the other hand to excite in us those passions which shall cause the actual events of life to move us more deeply, and awaken our susceptibility for receiving impressions of all kinds. For we do not here require absolute experience to excite these emotions, but only the appearance thereof, which art substitutes for sheer reality. The possibility of this illusion, by means of the representations of art, rests upon this, that every reality must pass through the representative medium before it can be cognised by the mind or acted on by the will, and therefore it is immaterial whether we are acted on by external immediate reality, or receive our impressions through other means, viz., pictures, signs, or forms which represent the qualities of this reality. Man can also picture to himself unreal things, as if they absolutely possessed reality. Therefore, whether we receive the impression of a situation, a relation, or the subject-matter of a life through the medium of external reality, or only through the representation of it, in both cases we are sufficiently affected to sorrow and rejoice, to be moved or agitated according to the nature of the subject, and in both cases we run through, in quick succession, the feelings and passions of anger, hate, pity, anxiety, terror, love, esteem, wonder, honour, and fame.

#### Towers and Spires.

J. DALLAWAY.

Old St. Paul's spire, of wood and lead, was 520 feet high; St. Stephen's, Vienna, 465; Strasburg, 456; Salisbury, 387; Norwich, 317; and Chichester, 290. The singularly beautiful spire of Louth, in Lincolnshire, was begun in 1502, and finished in ten years, by John Cole, architect, at the expense of 305*l* 7*s* 5*d*; it is 134 feet high, exclusively of the tower—total 282. Grantham, 144. The central spire of Lichfield is 258 feet high, and those of the façade 185 each; St. Michael's, Coventry, 300, which was built in imitation, and very probably by the same architect. The last-mentioned are all of stone. The spire of St. Andrew's, Worcester, which is extremely elegant, was built in the eighteenth century by Nath. Wilkinson, an uneducated mason. The height from the parapet of the tower is 155 feet 6 inches, the thickness of the walls of the spire is 20 inches, and under the capital and weathercock only 6½ inches. From a survey of Salisbury Cathedral it appears that the spire did not form a part of the original plan, but was added many years after its completion. The spire of Chichester Cathedral resembles it very nearly on a smaller scale, and was traditionally the work of the same architect. Of the twenty-two cathedrals in England, Salisbury, Chichester, Lichfield, and Norwich have most beautiful central spires; those of Oxford and Rochester are not worth noticing. The spire of old St. Paul's was finished 1221; Sarum, 1256; Chichester, 1270; Norwich, 1278; Lichfield, 1370; St. Michael's, Coventry, 1395. Magdalen Tower is 122 feet high, diameter 26. The cathedral at Gloucester, 224; Lincoln, 288; Canterbury, 235; Ely, 270; York, 234; Durham, 210; Worcester, 196; Wrexham, 132; Doncaster, 152; Derby, 174. Towers of Beverley, 198 each—the prototypes of those of Westminster; St. Stephen's Church, Bristol, 124; Taunton, Somersetshire, 153; all of which were built between 1400 and 1520. Towers of this age in Gloucestershire and the West of England are very frequent and beautiful. The tower built by Giotto in 1334 at Florence is 264 feet high, with a diameter of 46. The Falling Tower at Pisa is 188 feet high. The tower at Boston, in Lincolnshire, is finished by an octangular louvre, having in the whole an elevation of 282 feet. It was built about the year 1309, probably by the Flemings established there, and is said to resemble that of the great church at Antwerp. At Bruges I remarked a similar tower attached to the town-house, and another at Brussels. The central tower of the abbey of St. Oüen at Rouen, which is octangular and of the same date, is 240 feet high. The lantern tower at Ely is 170, and of a similar construction. Another at Peterborough is 136 feet from the floor. The tower of St. Nicholas in Newcastle-upon-Tyne is 194 feet high, and has a spire formed upon open arches, as a superstructure supposed to have been added in the reign of Henry VI. This idea was afterwards adopted by Sir Christopher Wren, in the tower of St. Dunstan in the East, London.

Mr. Whitworth Wallis, keeper of the Birmingham Municipal Art Gallery and Museum, on Tuesday delivered a lecture to the members of the Birmingham Architectural Association in the library of Queen's College on "Pompeian Art," being the third of a series which he has given before the members of the Architectural Association. The lecture, like those which had preceded it, was illustrated by limelight views.

## NOTES AND COMMENTS.

THE wisdom of the Belgian Chambers in voting a sum of money for the purchase of manuscripts from the PHILIPPS Collection in Cheltenham is now apparent. The country has by means of it come into possession of treasures which will be invaluable to posterity. Sir THOMAS PHILIPPS was one of those men who knew how to turn events to their advantage. Seeing that Belgium was a battlefield during the NAPOLEON epoch, he concluded that many people would in consequence be deprived of means, and would be ready to sacrifice things to obtain money. He was rich and influential. During forty years it was the business of his life to seek after manuscripts in convents that were poor or were about to be suppressed, and he was successful beyond the dreams of collectors. When Sir THOMAS died, his trustees, following the custom that is common, obtained power from the Courts to sell manuscripts to foreign states. Although Belgium was the most profitable field, he did not confine his researches to it, and his collection was enriched with Italian, French and English manuscripts, which will in due course find their way to the proper places. The Bibliothèque Royale, the archives office of Belgium, has secured manuscripts of which the country may be proud. Some are of historical interest, others are beautiful as examples of illumination and calligraphy. For instance, there are thirty-five volumes of the records of the Abbey of Cambron in the twelfth and thirteenth centuries. As the primitive binding of undressed hide is conserved, the volumes will have an additional charm in the eyes of bibliophiles. The records of the Abbey of St. Ghislain go back to the ninth century. The volumes from Villers contain, among other things, examples of fourteenth-century plain-chant. From the Abbey of Aulne, which was burnt by the French in 1794, no less than 110 volumes were saved by the peasants, and once more they find their way back to Belgium. One of them is "Euclid's Geometry," with a thirteenth-century commentary. But an enumeration of the manuscripts would occupy many pages. Some, like the diary of a gentleman in waiting, which is a history of the Spanish court between 1587 and 1599, with an abundance of pen sketches, should be reproduced. The charters and other documents relating to the cities and towns will be prized by a country where there is a passion for municipal history.

MR. WALTER EMDEN (who is a candidate for a seat on the County Council of the Metropolis) has offered to the Society of Architects three premiums of ten pounds each, which will be awarded for essays on constructional subjects, according to conditions which are to be arranged by the council of the Society. This year "Constructional Iron-work" is selected. The essays are to be sent to the Secretaries on or before February 28, 1889, and the prizeman is to read his composition on the following April 9. An essay is to contain 3,000 words, at least, and is not to exceed 6,000 words. It may be illustrated by five clearly drawn-up sketches.

TWELVE of the leading sculptors of France have agreed to take part in the competition for the memorial of CLAUDE GELÉE, or LORRAIN, the landscapist, which is to be erected in the public park of Nancy. A sum of 45,000 francs is fixed as the limit of the expense, and the work is to be handed over to the committee on April 1, 1890. The figures are to be in bronze and the pedestal is to be of stone or marble. The models, which are to be submitted before February 20, 1889, are to be one-fifth the contemplated size, and each competitor is to give a guarantee that the work will be completed for the stipulated amount. To the design placed second a premium of 1,500 francs will be awarded, and to the third one of 1,000 francs. The authors of the fourth, fifth and sixth designs will each receive 500 francs. All the premiated designs are to become the property of the committee, who will give them to the musées of the district.

M. PETITGRAND, one of the architects attached to the Historic Monuments Commission, and who has directed the restoration of the cathedrals of Puy and Séz, has been nominated as the successor of M. CORROYER in the charge of the works at Mont Saint-Michel. A letter to the Director

of the Beaux-Arts from M. CORROYER has appeared. He says he is less grieved by his dismissal than by the disloyalty which was shown to him in the defence made on his behalf before the Chamber. For fifteen years M. CORROYER has acted as architect at Mont Saint-Michel, and during that period he was compelled to struggle against the bishop, the monks, the municipality, and the engineers, all of whom were inspired by interests of their own, and in his contest he was loyally upheld hitherto by ministers and directors of the Department of Fine Arts. The book on Mont Saint-Michel which M. CORROYER brought out ten years ago was supported by the then Minister, and was crowned by the Institut. His independence created enemies, but the worst that could be brought against him was that he was a believer in religion. For that crime M. CORROYER has been turned adrift. He says proudly that his name is too closely associated with Mont Saint-Michel for any official act to erase it.

LOCAL Boards do well to insist on observance of by-laws, but they are not impeccable, and, as architects and builders well know, great inconvenience is often caused by their arbitrary decisions. A lesson has been taught to the Farnworth Local Board which we hope will have some effect in mending official conduct in other towns. A Mr. MULLINEAUX, or MOLYNEUX, was summoned before the Petty Sessions for a breach of the by-laws. On October 12 he deposited plans for a house and shop he proposed to erect. A week afterwards he received notice that his plans were rejected, but the Local Board did not condescend to give any reason for the withholding of approval. It was known that on two former occasions plans were lodged for the premises, but they were also unsuccessful. The building owner having three times failed, resolved to run the chance of having his buildings pulled down if they exhibited any deviation from the by-laws. It appears what the Board wanted was the forming of a street at the back of the premises. After hearing both sides the Justices decided that the local by-laws were observed in the construction, and they declined to grant a case for a superior court. It was held that a Local Board has no right to reject plans without pointing out the defects in them, and that a Board could not make it penal for a man doing something which he had a right to do. Elsewhere a different decision may be arrived at, but the Farnworth case deserves to be made a leading case.

It may not be known to all people who read articles about M. CLUSERET—the general of the Communists, whose election for Var has startled politicians in France and elsewhere—that he lives by the money obtained for his paintings. In the last Salon there were a couple of his paintings of scenes in Constantinople, in which city he appeared to have settled down as an artist after his condemnation to death in Paris for his services under the Commune. Few of the visitors to the galleries were able to recognise them as the work of the revolutionist who is a terror to the bourgeoisie. Latterly M. CLUSERET has taken to ceramic painting, and he was engaged in that kind of work when he was elected.

It is rather remarkable to find a work by a foreign artist on one of the walls of the Luxembourg Galleries. This honour has been accorded to M. ZORN, a Swedish artist, for his *Port d'Angleterre*, which figured in the last Salon and now finds a place among the works of modern French artists. Generally it was believed that the contents of the Luxembourg Gallery were to be entirely by Frenchmen.

By an Order in Council it is declared that the conditions of the Patent Act, 1883, under which an application for a patent is not to be invalidated by the exhibition of an invention at an international exhibition, are to apply to the Paris Universal Exhibition. Exhibitors are also to be relieved from the conditions of the Act, under which they were required to give notice to the Comptroller of Patents of their intention to exhibit the article afterwards sought to be patented. The regulations also apply to designs intended to be registered.

YORKSHIRE PENNY BANK, HALIFAX.

THIS building is situated at the corner of Waterhouse Street and John Street, Halifax. On the ground floor is a large, well-lighted banking-room, with manager's-room, packing-room, and safe; retiring-rooms for clerks, and additional store-room on the basement. The banking-room is heated by hot-water pipes and lighted and ventilated by means of a sun-burner, additional light being obtained from Wenham lamps fixed on the clerks' desks and public counter. Warm fresh air is supplied by passing it over the pipes before entering the room. The building is faced with Halifax stone (Ringley), and covered with green Westmoreland slates. All the windows are fitted with wrought-iron casements fixed to the stone jambs, and glazed with plate-glass and clear glass in leads. The banking-room is fitted up with walnutwood counter and desks and panelled dado; the floor in front of the counter is of mosaic, and behind of polished wook blocks, and the ceiling is richly panelled with moulded ribs and cast ornaments of plaster. The staircase is of hard stone, with wrought-iron balustrade, and has a dado of unglazed tiles which extends round the corridors. This stair is continued to the top of the building, and receives additional light from the lantern which forms the turret at the angle of the building. The offices are arranged in pairs, the woodwork being mostly pitch-pine, finished with varnish. They are provided with open fireplaces, having polished wood chimneypieces and grates set in tiles, and are supplied with fresh air from a "patent ventilating lintel" over the doors, at times when it is not convenient to open the windows. Each set of offices is also fitted with speaking tubes from the entrance in John Street, with electric call-bells instead of the usual whistle. The building has been erected from the designs of Messrs. PERKIN & BULMER, architects, of Leeds. The bank fittings were specially designed by the architect; the mosaic floor and tiles are by Messrs. E. SMITH & Co., of Coalville; and the wood-block floors by the Wood-block Flooring Company, Hartlepool. Messrs. KAYE & SONS, Leeds and London, supplied the locks; the pavement lights are by Messrs. HEYWOOD & Co., London. Mr. CLIFF acted as clerk of works.

The cost of the entire scheme (not including site) will be about 5,000*l.*, and the work has been carried out by Messrs. J. CHARNOCK & SONS, Pellon Lane, Halifax, as the general contractors.

At the opening of the building it was stated that in 1864 the business of the branch was conducted in the basement of the Halifax Mechanics' Institution. In 1876 it had so grown that it was necessary to open the branch daily. At that time 53,000*l.* was due to depositors, but the amount has increased to 647,000*l.*, 600,000*l.* of which was calculated to belong to the artisan class.

## THE ARCHITECTURAL ASSOCIATION.

THE fifth ordinary meeting of the Association took place on Friday evening, Mr. H. D. Appleton, president, in the chair.

The following gentlemen were elected members:—Messrs. A. Campbell, A. G. Wyand, D. M. Litster, J. K. Hunter, G. A. Luden, and A. W. Earle.

The PRESIDENT said a valuable studentship of 15*l.* was offered by Mr. Arthur Cates to enable a student to go to Paris to study the International Exhibition, both in regard of the construction of the buildings and the manufactures and architectural exhibits. The details, though not then finally settled, would, he hoped, be in their hands in a few days.

A hearty vote of thanks was spontaneously awarded to Mr. Cates.

Mr. WILLIAM DOUBLEDAY then read a paper on "Symbolism," which was well illustrated by drawings exhibited on the walls. On the conclusion of the paper a vote of thanks was passed to Mr. Doubleday.

## ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AN ordinary meeting of the Institute of Architects was held on Monday evening, Mr. Alfred Waterhouse, R.A. president, in the chair.

The SECRETARY announced the decease of Mr. C. F. Hansom, of Clifton, Bristol, and of Mr. H. J. Paull, of Manchester.

Mr. MACVICAR ANDERSON, hon. secretary, announced the award of the Ashpitel Prize, as made by the Board of Examiners, to Mr. H. E. Stelfox, of Manchester. Mr. Paul Waterhouse, M.A., and Mr. H. W. Burrows, had run Mr. Stelfox so closely for the prize that the examiners had great difficulty in deciding who was highest in point of merit, and it had been determined to award these two gentlemen exceptional prizes of merit.

The PRESIDENT stated that the following gentlemen had ceased to be members:—Messrs. W. J. Audsley, C. F. Livezey, P. J. Byrne, J. L. King, E. L. Swatman, and J. J. Woodman.

A ballot then ensued, when the following were elected:—*As Fellows.*—Messrs. H. Lord, Manchester; H. Bridgford, Manchester; W. Horton, Manchester; J. Ely, Manchester; J. Littlewood, Associate, Manchester; W. H. Littlewood, Associate, Manchester; J. S. Crowther, Manchester; J. W. Trounson, Penzance; J. Maxwell, Manchester; W. C. Tuke, Manchester; T. E. Bridgen, Manchester; E. Schröder Prior, M.A.; O. C. Wylson, Associate; and W. T. Allen. *As Associates.*—Messrs. P. E. Barker, Rusholme; J. D. Mould, Manchester; and J. A. Berrington, Liverpool.

Mr. JOHN BELCHER read a paper, of which the following is an abstract, on

## Musical Requirements in Church Planning.

Mr. Belcher said that the development of ecclesiastical music of late years forced certain problems upon the attention of the architect, and that in church planning the position of voices and instruments had now to be considered. The first introduction of organs was in the seventh century, but they were generally used in conjunction with other instruments. Minstrels' galleries might still be found in small churches, the west end being the favoured position. During the period from Henry VIII. to Queen Elizabeth instrumental music was still adhered to, but the objections of the Puritans were such that in 1644 nearly every organ in use had been destroyed. From the Restoration, however, to the present day, organs were recognised as essential. It was only fifty years ago that 32-foot pipes were first used in England, although on the Continent the organ became very large at the end of the fifteenth century, reaching a climax in the seventeenth and eighteenth centuries. In most cases they were forced to migrate from the chancel to the west end, in some to the transept, and where neither position was available, they were relegated to the triforium of the nave. The choir being seated in the chancel, the position of the organ near them seemed essential, but other eventualities, such as additional bodies of singers and an orchestra, had to be remembered. In future church planning these requirements would have to be considered. The organ should be in a position not less or much less in height than the nave and transepts, the so-called "organ-chamber" being a mistake. The size of an organ should not be regulated by the size of the building, but by the number of "stops," the combination of which regulated the extent of the volume of sound. A good foundation tone was always necessary, to secure which speaking room had to be provided for 8-feet, 16-feet, and even 32-foot pipes on the pedal organ. These dimensions had to be considered in providing sufficient space. The top of a chancel-screen or rood-loft was hardly a suitable position for an organ of any size, as, although it possessed attractions from an artistic point of view, it was prejudicial to the organ tone. Organists and organ-builders generally considered that in fairly large churches the organ should be raised about 12 feet above the ground, and a divided organ could not be recommended. Proper and easy access to every part for repairs and tuning should be provided, and attention given to the position and space for the "feeders." An equable temperature was also important. The organ-case might be treated as an enclosure, in the way usually adopted by the Italians, having no special relation to its contents, wholly or in part concealed; or in the general, and the author thought appropriate, way of using some of the pipes themselves as decorative features in a framework enclosing the other parts of the organ. The use of iron in the construction of an organ-case he protested against, while wood was a material in sympathy with the organ, and the most consistent for the construction of its case. Sound travelled so slowly, that any division of choir, organ, or orchestra was destructive of precision, and they should therefore be compactly arranged, and as far as possible on the same plane. Mr. Belcher then described a sketch of a plan by himself to illustrate his meaning. The organ was placed in a special transept, east of the great transept, equal in height to the rest of the church, and forming the western end of the morning

chapel; it was virtually open on three sides, but was slightly sheltered; outside the main wall, and between the buttresses, a staircase with a wide landing served as a tuning-place for an orchestra before entering the gallery; this gallery, projecting into the chancel, gave space for an orchestra, which might be extended eastwards if required. The floor of the organ was 12 feet from the ground, the music gallery was lower, and as the floor of the chancel was raised by steps, all the performers were brought into close relation with each other and the organ. The usual north transept afforded an excellent position for grouping large bodies of voices adjoining the organ and orchestra, and easily under the control of a conductor at the western angle of the gallery. A corresponding gallery on the opposite side of the chancel would provide for female singers at ordinary services.

The PRESIDENT invited a discussion of the paper, which, he said, was both interesting and suggestive. The only fault he could find with the paper was it had been so short.

Mr. STATHAM proposed a vote of thanks to Mr. Belcher for the exceedingly practical paper. As to its brevity, also, it might serve as a model for other papers. He was much pleased to have heard the subject dealt with from so useful a point of view by an architect of Mr. Belcher's ability. One thing he hoped they would feel, namely, that the organ chamber was doomed. It was a cruel thing to place an organ there, for it was utterly lost in such a position. The difficulty was that various complications arose from the requirements, first of ritual, secondly of singers, and thirdly from the question of money. He did not profess to know much about ritual requirements, but he knew that many a modern clergyman would look black at a proposition to place the organ at the end of the chancel or behind the altar. But from a musical point of view that was the best position. The organ should have a central position that the sound should go well down the church; it should be near the voices, and the voices in front of the chancel, so that the position behind the altar, if unorthodox as to ritual, was musically orthodox, for it combined the fullest musical effects with the very practical matter of supporting the voices. Next best was the old position in the west end. There a fine organ was always built, but an organ far too large to accompany the choir. The organist had in it what he wanted, namely, an instrument to show off his fugues on. One way out of this difficulty was by use of the long movement which electricity had put in our power, but he thought the real solution would be to have a small choir organ near the choir, as well as the large organ at the west end for grand musical effects. He differed with Mr. Belcher that it was disadvantageous to the organist to be at a distance from the choir. But where money was not limited there could be a small choir-organ, and a large one for grand occasions and for accompanying congregational singing. He did not think the position on the rood screen in cathedrals was at all a bad one, though it was something strange to hear that the position was considered good for artistic effects, when they remembered the complaint of the architectural effect at St. Paul's being spoilt by the "box of whistles." If the organ thus placed sounded harsh, that he thought would be the fault of the organ. The position was a capital one; but this position was abandoned when organs became very large, and then the organ—as at Worcester Cathedral—was stuck about in all corners of a building. In such a case he would place the manual pipes on the screen, and the pedal pipes lower down. In the design of organ cases he thought an effect of harmonious contrast might be made with the large pipes, which were mostly of wood, and generally kept in the background, and the metal pipes. In the St. George's Hall organ the wooden pipes were disposed in a semicircular arrangement at the back.

Mr. WM. WHITE, F.S.A., seconded the vote of thanks. He said he did not remember that the subject had ever before been discussed at the Institute, though it was one of the most practical of questions in regard of church arrangements with which architects had to deal. He agreed with Mr. Statham's suggestion for two organs for large churches, though they would hardly be required in a small building. In the case of two organs, the position of the choir-organ was open to question on several accounts; but the position over the chancel screen was a very good position, if kept sufficiently low and subdued so as not to interfere with the general effect. The organ must not be too large for the building, or it would be an obstruction to the chancel. Mr. Statham had referred to western organs in Roman churches. It was not a question as to Roman and English churches, but as to the manner in which the church services were conducted. In English churches, the first consideration was that of congregational uses and not the æsthetic portions of the service—parts of the service that might and ought to be purely æsthetic, and that were to be listened to but not joined in by the congregation. In this case a western organ was essential unless an orchestra were substituted for it. Much had been lost in English churches by a too great abandonment of singing, which was superseded by the organ. That had its origin in the dull, dreamy tunes of the old

performers in the western galleries. When a change came in the services, a change necessarily followed in the character of the accompaniment; but instead of substituting an orchestra at the western end, the radical plan of sweeping away the western organ altogether was adopted. It was impossible either to look for or to expect æsthetic services in the large bulk of country or village churches. There were not the voices nor the means to provide them, and consequently the services must be almost exclusively congregational, and the organ must lead and support the choir in front without drowning it. The evil was that an organist was not content without an organ for æsthetic purposes, and he had little regard for drowning the choir. Organ-builders would strive after large instruments, and organists supported them in that regard. Not one organist out of ten but cared more for the organ than for the choir. As to placing the organist's seat under the canopy, organists preferred to have the seat there. The organist preferred to be somewhat sheltered from the great volume of sound that would come to him if seated to the front, and he could thus better judge if the performance of the choir and congregation and the instrument were in proper touch. In dealing with the organ-case, his (Mr. White's) first requirement was to know from the organ-builder and organist the arrangement and position of the pipes that they decided as the most fitting for the construction of the particular instrument, and, informed on these points, he endeavoured to clothe the work in architectural form. The aim should be to harmonise the requirements and construction of the organ as determined by the particular necessities, so that they should fit in with the purposes of the building.

Mr. C. FORSTER HAYWARD, F.S.A., said that organs were often overdone in English churches. Not only were choirs drowned, but the organ was too large for the building; and he knew of many places where this arose from having too much money. In the last case he had to deal with it would have been much better if there had been 200% or 300% less to spend on it. The organ was placed exactly in the position on one of the plans shown by Mr. Belcher as an example of what to avoid, and the pipes were so near the roof that if the full power was used something would occur; some said the roof would come down. The organ was blown by hydraulic power accompanied by a continual squeaking, a disagreeable accompaniment that apparently could not be got over. He wished the use of instrumental music besides that of the organ were more common in English churches. As to organ-cases, the finest, he believed, was one put up of late years by Mr. Burges—and none of the pipes were to be seen—in the speech-room of Harrow School. The arrangement of western organ and choir organ was carried out at Amiens Cathedral with a most beautiful effect.

Mr. M. B. ADAMS referred to Mr. Street's treatment of the organ at St. Mary's Church, Paddington, and at St. Augustine's Church, Kilburn. He (Mr. Adams) was not in favour of florid music, or anything approaching a concert in churches.

Mr. RALPH NEVILL, F.S.A., said one of the most important points brought forward was that relative to placing the organ at the east end, behind the altar. As Mr. Statham said, it would be a capital place for sound. Many parsons would hold up their hands with horror at the proposal, but there were many also on the look-out for novelties who would be pleased with it. Builders, too, would only be too glad to get out of having to put in an east window. There was no necessity to show the pipes of the organ. The front of the instrument could be designed as a reredos, and thus give an appropriate and ornamental ending to the church. The apsidal form could by this expedient be well utilised. The altar must be, as they had been shown, in the chord of the apse, and not placed against the wall, and then the inner and outer effects of the apse would be fully gained. In placing an organ a certain amount of compression was required to give full effect to the volume of sound from the instrument. It was advantageous to have the organ at a little distance away from the choir, as it gave the choir a better chance of being heard. As to the position on the screen, it depended where the congregation was placed. In cathedrals there were occasionally two congregations, one in the nave and the other in the choir; and in an ordinary way it might be a good plan to have the organ between the two. The western position was, after all, the best place. The greatest success he knew of was at the pro-Cathedral, Kensington. The organ was a splendid instrument, and there were first-class singers. The effect of the organ's tones rolling away through the building overhead was such as he had never before heard. No organist, he thought, could by the use of electricity get quite the grip necessary to produce the proper effects.

Mr. E. J. TARVER said that organs were placed on the north side of churches because the temperature in that position was more equable. At the church of the Miracoli, Brescia, a most ornamental feature had been effected by placing the organ boldly in the western end.

Mr. G. AITCHISON, A.R.A., said the only organ-case of any merit that he knew of was at Siena.

The President then put the vote to the meeting, and it was carried by acclamation. Mr. Belcher replied, and the proceedings terminated.

### MANCHESTER ARCHITECTURAL ASSOCIATION.

AT the fourth ordinary meeting held on Tuesday at the Diocesan Buildings, Mr. A. H. Davies Colley, the president, in the chair, a discussion was opened by Mr. H. B. Bare upon "Architects and Handicraftsmen." The foundation of a chair of architecture and the allied arts, such as sculpture and decorative painting, was suggested as very desirable at Owens College, Manchester, and other colleges of the Victoria University. The professor would direct a course of mental and manual artwork for those who afterwards might adopt any of the special branches of artistic professions or handicrafts. The result would be a sounder and wider education in art, and a greater sympathy between all professions and all handicrafts, which must before long improve art of every kind. Messrs. Hodgson, Mould, Stelfox, Mee, and the chairman took part in an animated discussion which followed.

### CAVE ARCHITECTURE.

A MEETING of the Archaeological Section of the Birmingham and Midland Institute was held at the Institute on Wednesday, when Major-General A. Phelps read a paper on "The Cave Architecture of Western India." Mr. Howard S. Pearson presided, and, in introducing the lecturer, said that he was sure they would all listen with pleasure to the lecture, the subject of which was of great archaeological interest. The lecturer having briefly referred to the cave-temples of the Island of Elephanta, so named after the great elephant carved in stone which had formerly stood there, said that the oldest caves were the work of the Buddhists, who had been forced to flee into the jungle and other hiding-places on account of their religion. These caves, which had sprung from single cells, were all carved out of the solid rock. They had in all probability been picked out with hammer and chisel, as chisel-marks were to be seen on portions of the rock. There were over a thousand such caves in India. Limelight views of some of these caves were exhibited, as well as several views of Hindoo temples also carved out of the solid rock. One of the temples shown was, so the lecturer stated, 150 feet in height and 270 feet in depth. A vote of thanks was passed to Major-General Phelps.

### THE GLOUCESTER CATHEDRAL REREDOS.

A SPECIAL meeting of the Provincial Grand Lodge of Gloucestershire Freemasons was held at the Masonic Hall, Cheltenham, on Tuesday, Sir M. E. Hicks Beach, Bart., M.P., Provincial Grand Master, presiding, to consider resolutions of the committee appointed at the last meeting on the subject of the decoration of the reredos in Gloucester Cathedral. The reredos was erected fifteen years ago by the Freemasons of the province, at a cost of £1,300, the work being executed by Redfern from designs by the late Sir Gilbert Scott. It is a white stone structure, divided into three principal compartments, in which are groups of figures representing the Nativity, the Entombment, and the Ascension of Our Saviour; figures of Moses, St. Peter, St. Paul, and David occupy the minor niches at the sides of these compartments; and under the canopies formed by the tabernaclework above are nine figures of angels, bearing the emblems of Our Lord's Passion. The cathedral authorities being desirous of decorating the interior of the niches of the reredos in order to throw the figures more into relief, and also of gilding the details of the tabernaclework, a communication on the subject was laid before the meeting of Provincial Grand Lodge at Stow-on-the-Wold in May last, and a committee was appointed to ascertain the views of the brethren of the province, and to take such action in the matter, by sanctioning the work or otherwise, as might seem to them desirable. The committee authorised as an experiment the decorating tentatively of a section of the reredos in the way proposed; and this having been done, and the work inspected, the committee approved of its effect, but decided to ask the Provincial Grand Master to relieve it of further responsibility by again referring the question to Provincial Grand Lodge. The proposal to accede to the request made for the decoration thus came forward for discussion at the meeting on Tuesday, supported by the approval of the committee, and endorsed by the unanimous vote of the Royal Gloucestershire Lodge of Gloucester, which promised twenty-five guineas towards the

cost of the work. Mr. Nelson Foster proposed that the decoration of the reredos be carried out in accordance with the plan approved by the committee at a cost not exceeding 300*l.*, and Mr. J. Walker seconded the proposition. An amendment was proposed by Mr. Gwinnett practically negating it, and this was seconded by Mr. Moore. The Provincial Grand Master expressed his opinion in favour of the decoration, and Mr. J. Winterbotham his against it. On a vote being taken, the amendment was rejected by a considerable majority, and the original resolution carried.

### TECHNICAL EDUCATION.

ON Wednesday Sir Lyon Playfair distributed the prizes to the students of the schools in connection with the City and Guilds of London Institute, and in addressing the assembly observed that when the Guilds were founded in the twelfth century they had a double purpose—first, to protect skilled labour against the encroachment of the feudal laws, the second purpose being more nearly related to that which they were now performing—to restore and develop lost arts and sciences, and to act as teachers to pupils. The word "guild" was a modern innovation. In their ancient charters the guild was called *universitas*—a word which at that time meant a teaching corporation, and it was applied as closely to a university of smiths, or tailors, or carpenters, with the same object and with the same right to use it, as to the Universities of Oxford and Cambridge. The whole idea was founded upon teaching. The apprentice was bound to learn and the master was bound to teach, and a better technical education for the period he could not conceive. The effect of the introduction of machinery was to make the guilds alter their functions altogether, and the relation of master and apprentice was by the same cause changed into the position of capitalist and workman. Machinery brought about a great subdivision of labour, by which the workman was relegated to one small corner of his industry, and did not know the whole mystery of his craft, as he did in the old days. Until recently, the City and Guilds Institute and other promoters of technical education arose, he had no means of dignifying his labour by understanding the whole field of the industry in which he was engaged. The ignorant workman woke one morning and found that a new machine had been invented which dispensed with his labour. He had learnt to do nothing else, and he was added to the large army of the unemployed, not having had the education to adapt himself to the dislocations of labour which were happening every day. The City and Guilds Institute had been formed to give men the opportunity of acquiring knowledge which would enable them to adapt themselves to the new order of things when such dislocations occurred. The competition of the world was becoming a competition of intellect, and if in any one branch we fell below that of a foreign country we should be beaten. The success of nations in the future would depend on the trained intelligence—or, in other words, the technical education—of their working men. The guilds had recognised the necessity of adapting themselves to the industrial progress of the world, and had shown their readiness to promote the industries which they were founded to promote. He considered that the country owed a great debt of gratitude to the City and Guilds Institute, which had set a noble example to the whole kingdom.

### GREEK STATUETTES.

FIFTY terra-cotta statuettes, which were found in the Greek cemetery of Myrina, on the north coast of Asia Minor, about thirty miles from Smyrna, have been lent to the Birmingham Art Gallery by Mr. George Dennis, the Consul-General at Smyrna. They range, says the *Birmingham Post*, from 3 inches to 10 inches in height. The majority of them were probably executed about B.C. 200; but there are some of a later period. It is, however, very difficult to assign a positive date to these terra-cottas. It is customary to attribute those which display the best art, without archaic features, to the earliest dates; those of coarser style, with less attention to detail, to the later period. It is rarely the case that terra-cottas found on the coast of Asia Minor have archaic features, which seems to indicate that the use of these figures as sepulchral furniture was not common in Asia Minor—at any rate in *Æolis*—at a very early period; indeed, their distinguishing features mark them as belonging to the decadence of Greek art, though most of the specimens show exquisite form and some are of exceptional beauty. The feeling, however, for plastic art, which the Greeks possessed in such a high degree, has here given place to a sense of the picturesque, and the sculptors have taken the figures from everyday life—walking, dancing, draperies flying in the wind, with little of that repose which stamps the finest period of Hellenic art. It will be noted

what dexterity of execution and what cleverness of construction these little figures possess. The arms of some are movable, some are evidently mere playthings, yet they are so admirable as to furnish artists and archaeologists with much ground for study. These little terra-cottas were evidently made in a mould, and the artist would remodel or retouch with the modelling tool the various details which could not be brought to perfection or sharpness by any mechanical process. Many of them, like the celebrated Tanagra statuettes, have been coloured; some of the tints still retain their original freshness. In order to colour them they were dropped in a bath of whitewash, and then tinted a pale pink, red, blue, and yellow, and where the colour has disappeared the original coat of whitewash may now be seen. On the shoulders of some of the figures are inscriptions, two or three letters marked in the clay whilst soft, which probably represented the name of the potter.

One of the most interesting figures is that of a woman dancing, gracefully poised on one foot, in the attitude of turning round; she wears a Doric chiton or tunic, which leaves, of course, the right leg bare. The figure is full of expression and vigour of movement, and the flow of the drapery is dexterously rendered. Another, of great beauty, is the figure of a woman leaning against a pedestal, with right hand on hip, whilst the left holds up the mantle or cloak. The head is encircled by a stephane or head ornament worn by a goddess, so well done as to indicate a fine period of art. Some of the figures of Eros, crowned with garlands of fruit and flowers, are excellent, and show a remarkable sense of movement. A figure of a youth, placed on the uppermost shelf, and wearing a short tunic and a chaplet of wool and flowers, is the best. The figure of a winged Victory, with the right arm extended, holding a wreath and wearing a Doric chiton, may be assigned to a late period; the modelling is defective and "scamped." A figure of interest to the archaeologist, and possibly to the dramatist, is that of an actor wearing his mask. Few statuettes of this kind have been found, though at Berlin are three or four admirable examples of the kind from Tanagra. The actor wears a long mantle and a chaplet of flowers and wool; the mask, with a broad grin, and the flowing beard are finely modelled, and the purpose of illusion is fully achieved. Next to this is an exquisite seated figure—only 4 inches high—of a girl wrapped in a cloak, and leaning against a Hermes. This little figure, of great refinement, closely resembles the Tanagra works, as, indeed, do most of those fully clothed. Together with this figure of the seated girl should be noted the poetical little figure of Eros, muffled, and with extended wings. It may be hoped that this interesting collection will be secured as a permanent addition to the gallery.

#### AN IRISH CHURCH.

THE following remarkable statement is by the rector of Ovoca:—

I have noticed for the last three years that there was a considerable amount of damp in the walls and tower of Ovoca Church, and on drawing attention to the fact I was told that there must be something wrong at the roof of the tower, and possibly at the down-spouts, but nothing more than could be easily rectified, or if not this, that the new mortar was merely drying out; and so, waiting a favourable opportunity to have the matter investigated, and not knowing but the latter might be the case, and having very much to do of parochial work in a new parish, I put off the inspection till I could have the damage properly attended to, as we were soon to have our schoolroom repaired. In the meantime, particularly during wet weather, we saw that there must be something radically wrong, or there could not be so much damp visible; and at the visitation before the last I thought right to mention this, when we determined to have a professional inspection of the church.

The consecration dates from 1870—only eighteen years ago—and so the church is practically new, and it is this new appearance which has deceived many as to its true condition. The building cost, I believe, 3,300*l.*, and the church is one of the handsomest in Ireland.

In the spring of this year I had an inspection made by two practical builders, but during last winter I knew enough to satisfy me that the case was much worse than any one thought, for the ceiling of the vestry-room had in part fallen, disclosing the rotten rafters overhead.

The inspection justified our worst suspicions, and we found all the woodwork in the vestry-room, which is under the tower, perfectly rotten. My health, unfortunately, with constant work, could not carry me through the summer; so, much against my wish, I had to postpone this important matter and recruit at the seaside. On my return in September, when I had workmen at the church doing some improvements, I examined with them the roof, and we found that two of the principals had begun to rot. I then asked Mr. Fuller to come

and make a report, which I enclose. The result was worse than before. The tower has four storeys. Of these the floors of three are quite rotten, and before long there will not be a sound plank in the whole tower. The damp, which has already reached the roof, will spread, and I am assured that in less than a good lifetime from the present the church—built only eighteen years—will be simply a ruin if the present state of things is allowed to continue.

To avert this I think it is my plain duty to call attention as publicly as I can to the facts. The cause of the damage is as follows:—When the church was built it was not allowed time to settle, as every building requires, but the pointing was done in cement while the scaffolding was being taken down. The church walls then settled, and the pointing of course broke. The rain beating against the walls enters the cracks and destroys all before it.

If the whole outside of the tower and church is pointed anew, the walls will be safe for the future, but this will cost over 300*l.* As it is, the parish has suffered so many losses, the mines are idle, many people have left, and those who are here, while very willing to help, have not the means to do all this most necessary work. If we erect a scaffolding it is about as much as we can do. The church was built when all the mines were going, and every one was well off, but now things are altered greatly.

If the work is not done one of the finest churches in Ireland will fall into ruin.

[Copy of the Architect's Report.]

I have inspected Castlemacadam Church, as requested by the rector. Much injury is being done by the want of proper staunching of masonry. The two gables at the west end are suffering seriously from damp, which is of course affecting the adjoining roof timbers. Damp also shows at the south-east angle near the chancel arch, and the timber which is in contact with the wet masonry is beginning to decay. The vestry is in a deplorable state. The floor has sunk, which shows that the plates under joists—if not the joists also—have rotted. The joists of the ceiling, particularly on east side, are rotten, and the wall plaster is either off or falling off. On an upper stage of the tower one of the main beams on which the floor is carried is seriously decayed. This state of things should not be allowed to continue. Steps should be taken this spring to cure the defects.

J. F. FULLER, F.S.A., Architect.

#### KIRKSTALL ABBEY.

AT the conclusion of the sale of the Cardigan Estates, the auctioneer, Mr. Chinnock, said he had an intimation to make which he was sure would give the company great pleasure, and that was that Kirkstall Abbey had been sold privately, and though he was not at liberty to mention the name of the purchaser, he could tell them that it had fallen into very good hands. He did not know what to say about the Leeds Corporation, except that they should be a little bit quicker, and adapt themselves more to the times. They had lost a splendid chance. The gentleman who had bought the Abbey, Mr. Chinnock added, was acting on behalf of several gentlemen of the town. It subsequently transpired, says the *Leeds Mercury*, that a contract had been drawn up between some gentlemen and the vendors for the sale of the Abbey and the Abbey House at the reserve price. Mr. Edmund Wilson was informed of the fact by telegram, and he immediately, on his own responsibility, purchased the two estates for 13,500*l.* Mr. Wilson was compelled to take this step on the spur of the moment, without consultation with any one else interested. Otherwise the Abbey would have passed into other hands. It will be remembered that the reserve price put on the Abbey the other day was 10,000*l.*, and on the Abbey House 3,500*l.*, so that the vendors have succeeded in getting the full amount. We are not in a position to state what will be done with the properties, but the public will be delighted to learn that the venerable ruins of Kirkstall have fallen into the hands of Leeds gentlemen in whose care they will not be allowed to suffer.

#### GREEK EXCAVATIONS.

THE Winckelmann anniversary was celebrated on Friday night (writes the Athens correspondent of the *Standard*) at the German Archaeological Institute in that city, when Dr. Dörpfeld, the principal, delivered an important address to a brilliant audience on the results of recent excavations in Greece as bearing on the history and development of ancient art. Dr. Dörpfeld, who, with Dr. Schliemann, has made a special study of the discoveries at Mycenæ, Tiryns, and Orchomenos, proceeded to enumerate the relics of prehistoric palaces and other edifices recently brought to light in the territories inhabited by

the ancient Greeks. On examination and comparison with other ancient monuments, these remains showed an unmistakable resemblance to ancient Asiatic architecture, while at the same time they were not dissimilar to the Hellenic temples of later periods. Dr. Dörpfeld holds that the ancient Greeks borrowed their different styles from Egypt and from several of the ancient peoples of Asia. The builders of the Mycenaean period were, he believed, Phoenicians. The remains of the edifices at Mycenæ and Tiryns bore a wonderful resemblance to the Jewish Temple at Jerusalem.

#### Longton Cottage Hospital Competition.

SIR,—Will you afford us space for protest against another unsatisfactory competition? The above-named was limited by special invitation to some seven or eight local architects, amongst whom we had the misfortune to be included. At the outset we obtained a conditional promise that an assessor should be appointed, or we should not have entered the competition. In due course the secretary apprised us officially of the assessor's appointment, and in reply we wrote expressing satisfaction that the trustees had adopted this course. Later (November 28), he informed us:—"The trustees have now decided upon two sets of drawings to select from, viz., Mr. Ford's and Mr. Taylor's." (He added, "It only remains to say that your plans are at your disposal, and may be removed by you whenever it suits your convenience.") Now from inquiries that have since been made the following facts have been ascertained:—(1) The assessor never saw any of the designs sent in, except those of the two favoured competitors already named, the plans of the other invited competitors being virtually suppressed. (2) The two favoured competitors had access to view the whole of the designs before the assessor entered upon his duties. On the other hand, the unfavoured competitors (such as ourselves, Mr. Lynam, and all the rest), some of whom had asked for, or been promised, that privilege, were never allowed to see the designs at all. Comment appears needless.—We are, yours truly, W. SUGDEN & SON, Leek: December 18, 1888.

#### Cash on Delivery.

SIR,—An instance has recently come before me of a consignment being sent from the Continent by this Company's Harwich route with a considerable disbursement, or "Paid on," and, although the consignee knew nothing of the case, he accepted it, paying the charges. When the package was opened, the contents were found to be of little value, and had never been ordered. The consignee thereupon applied to my Company to refund the disbursement and the charges, but, according to the Continental law, acceptance of goods, and payment of the charges, forfeits any claim against the sender. The proper course would have been for the consignee to refuse acceptance until he had satisfied himself that it was a bona-fide transaction. I shall be glad if you will insert this letter in your paper as a caution to the public against accepting goods on which there are heavy "paid on's" or other charges, and which they do not expect, as this season of the year is particularly favourable to such transactions, on account of the numbers of presents that are being received.—I am, Sir, your obedient servant, F. GOODAY.

Continental Traffic Manager, Great Eastern Railway  
Liverpool Street: December 15.

#### SCHOOL BUILDINGS.

**Stratford.**—New Sunday-schools in connection with the Congregational church have been opened. The schools are built at the rear of the church, with which and the adjacent lecture-room they are connected by means of corridors. Accommodation is provided for about 350 scholars. The buildings have been most substantially constructed of brick, with stone dressings, by Mr. Stanton, of Evesham, from the designs of Mr. T. T. Allen, architect, of Stratford, the total cost being between 600*l.* and 700*l.*

**Shrewsbury.**—The Congregational Sunday-schools have been reopened after extension from the plans of Mr. A. B. Deakin, Shrewsbury. The new buildings, which are built of red brick, with stone dressings and moulded Ruabon brick string-courses, consist of the extension of the schoolroom 10 feet wide, making the size of the room 50 feet by 40 feet, the enlargement of the classrooms over the schoolroom, and the erection of a new wing on the ground-floor, containing infants' schoolroom, library, china closet, lavatory, and other con-

veniences, entrance-hall with stone staircase, and six new classrooms over. A house with all necessary conveniences has also been built for the accommodation of the caretaker. The building is heated with hot water by Mr. Jackson, of Newcastle, and ventilated by Kershaw's pneumatic ventilators and fresh-air inlets. The work has been carried out under the superintendence of the architect, by Mr. Thomas Morris, builder, St. Austin's Friars, and both these gentlemen have carried out their duties in a thoroughly efficient manner. The large schoolroom is lighted by five of the patent Wenham lamps, and the whole of the gasfittings have been rearranged by the Shrewsbury Gaslight Company. The painting was done by Mr. Stanley, Shrewsbury, and the glazing by Messrs. Ravenscroft & Mansell.

#### NEW BUILDINGS.

**Bank of England Branch, Fleet Street.**—The new building near the Law Courts, erected on the site of the Cock Tavern and adjoining buildings, was opened on Monday. The style is Italian. The building has a frontage to Fleet Street of 80 feet and an area of 4,000 square feet. It contains three lofty storeys, besides a deep basement floor, and is surmounted at the south-east and south-west angles by prominent towers, rising to a height of 70 feet. In sinking for the foundations the London clay was reached at a depth of from 18 feet to 20 feet below the street level. The basement walls are formed of blocks of dark Aberdeen and Cornish granite, between 3 feet and 4 feet in thickness, rising to a height of several feet above the ground line. The two elevations are faced with Portland stone, and decorated by the introduction of Shap and Peterhead polished granite columns. The principal entrance to the bank is under an archway and porch at the west end, about 9 feet in width, the entrance being fitted with ornamental iron gates, in the centre of which is the inscription "Bank of England." The banking-house, with the adjoining offices, occupies the whole of the ground floor, being 70 feet in length and 40 feet in width. The floor of the public part is laid in mosaics by Messrs. Burke & Co. The upper floors will be occupied as the manager's residence. The strong-rooms are in the basement, and are entirely enclosed within walls built of Staffordshire blue brick, consisting of several courses, each course being intersected and bound by strong hoop-iron. Messrs. Hobbs, Hart & Co. have supplied the safes and iron doors and grilles. The building will be lighted by electricity as well as gas. The premises has been erected from the designs of Mr. A. W. Blomfield, M.A., A.R.A., architect, Messrs. Dove Bros. being the contractors. The cost of the site was about 35,000*l.*, the foundations and basement cost 17,000*l.*, and the superstructure nearly 45,000*l.*

**Alloa.**—The town-hall and library presented to the town of Alloa by Mr. Thomson Paton, of Norwood, has been opened. The buildings are Gothic in style. They are built of sandstone, and present externally an imposing appearance, forming an important addition to the architectural features of the town. Mr. Alfred Waterhouse, R.A., is the architect, and under his direction a structure has been erected which, while it is picturesque so far as its exterior is concerned, is commodious and attractive inside. The style of architecture is a broad treatment of domestic Gothic. The building consists of two portions, one four storeys in height, and covering nearly the whole width of the site towards Church Street; and the other two storeys in height, extending backwards at right angles from the front portion. The library, reading, and recreation and classrooms are to the front, while the town-hall occupies the whole back portion. The central block of the front part projects beyond the general building line. The upper part is broken off with pilasters, and the centre terminates with an ornamental gable top. The main entrance is through a large semi-circular headed doorway in the centre of the front. It gives access to a handsome hall that rises right through the building to the roof. The main staircase leading to the various floors ascends at an easy gradient, and is lighted from the well. At the height of the second floor there are polished Peterhead granite columns. The walls of the vestibule and entrance hall throughout are covered with glazed Burmantofts faience in subdued artistic colours. There are large semi-circular arches at each side of the commencement of the staircase, and elliptical arches of various sizes are worked into the design at various parts of the staircase. Light for the hall is derived from the roof through a glass ceiling painted in conventional designs. The first flight of steps leads up to the mezzanine or entresol floor, from which the reading and billiard-rooms are entered. They are both spacious apartments, capably lighted from large windows which extend almost from floor to ceiling, and form one of the chief features in the front of the building. Oak galleries extend round three sides of each room at a height of 10 feet from the floor, and are lined with bookcases, while in the reading-room there are other cases containing books for reference placed round the lower portion of the apartment. Each room measures

32 feet by 19 feet. The librarian's-room is situated on the first floor, in a position from which easy access can be had to the galleries. The science and art classrooms occupy the other floors of the front building. The town-hall is a very handsome oblong apartment with covered roof, which has been so well arranged that from every seat in it a good view can be had of the platform. A large organ has been fitted up in it, and the walls and ceiling, the latter of which has been divided into compartments with heavy Gothic mouldings, have been decorated from designs prepared by the architect.

**Ditchingham.**—On Tuesday last a new mission-house was opened at Ditchingham, Norfolk. It consists of one room, 50 feet by 24 feet, easily divisible by a movable partition. Attached to the room is a small residence for two sisters in charge, and a small oratory. The roof of mission-room is of pitch-pine, and has trusses with cut queen-posts and wave boards. It is brick built, part half-timbered, and rough cast, and has cost 1,050*l*. This makes the eighth building erected by the All Hallows community since their settlement in this parish in 1859, when they built the House of Mercy. Since that time they have built two orphanages, a country hospital, and a priest's house. Since the year 1876 the Community House (a residence for the community), Holy Cross House (a memorial wing to the late Rev. W. E. Scudamore), and this mission-house have been erected, from designs and under the superintendence of Mr. Augustus Frere, F.R.I.B.A., London, the whole work having been ably carried out by Mr. Robert Morriss, builder, Ditchingham.

**Birmingham.**—At the expense of Mr. J. C. Holder some important additions have been made to the structure of the hospital (one of the oldest in the country, having been erected about the year 1780), with a view to improve the lavatory arrangements of several of the wards. The work consists of lavatory annexes to two of the pavilions containing the wards. The new building may be described as square towers with the angles taken off, forming on plan an irregular octagon, each being four storeys high, connected with the block to which it belongs by intercepting lobbies to secure independent ventilation. In each floor of the towers is a bath-room, lavatory, water-closet, and a wash-up sink, each with its separate enclosure for privacy. The floors are covered with sheet-lead. The walls have a high dado of white tiles, the upper part being cemented. Hot and cold water are supplied throughout, and the whole of the hydraulic and draining arrangements are in accordance with the best sanitary knowledge of the present day. In addition to the above gift, Mr. Holder has also defrayed the cost of ventilating the main drains, a work urgently required. The works have been executed in the best and most substantial manner by Mr. James Moffat from the designs of Messrs. Yeoville Thomason & Whitwell, architects, of Cannon Street, Birmingham.

**Saltash.**—The Cottage Hospital and Convalescent Home of St. Barnabas, built by the munificent generosity of Mrs. Ley, of Claremont, Saltash, was opened on Tuesday, December 11. The building occupies an elevated site in Upper Port View Road, commanding extensive views of the Hamoaze and neighbourhood. It is built of red brick, tile hung, with half-timbered oakwork. A conspicuous feature is the circular end of the chapel on the east side. Internally no expense has been spared to make the arrangements as perfect as possible. The whole of the east end of the building is occupied by a chapel. It is apsidal in form, and the interior is of red Berkshire brick, relieved by stone dressings and labels, the archery over the windows being of rubbed gauged brickwork. The roof is barrel-vaulted. The chapel is lighted by seven tracery-headed windows, three of which are filled with coloured glass. Seating accommodation will be provided for 24 persons. At one end of the chapel is a small gallery on a level with the upper landing, from which it is separated by a glazed screen. It is intended for the use of patients in the upper wards who may be too weak to walk down stairs. On the north side is an arched recess for the harmonium. In the opposite wall are two sliding lights, which, when open, will enable the inmates of the male wards to hear the singing in the chapel. Near the organ recess has been hung the dedication picture, depicting St. Barnabas, painted by Mr. E. Fellowes Prynne. When completed there will be a division between the sanctuary and the nave, and the panels on the walls will be decorated. On the basement are a heating chamber, kitchens, scullery, ice-house, laundry, and mortuary. As the ground slopes to the south, the basement rooms are not underground and gloomy, but well lighted and cheerful. Special attention has been bestowed on the sanitary arrangements, which are made as perfect as possible. Each ward has its own lavatory and other conveniences, and there are no drains running under the building, all the pipes being carried away on the outside and ventilated. The whole building is heated by hot-water pipes, supplied by Bennett Bros., Liverpool, and the wards are fitted with Messrs. Malcolm, Tester & Co.'s pneumatic bells. There is also a lift communicating with the upper landing. A good supply of water is

obtained from a well on the premises. The work has been substantially carried out by Mr. R. W. Rowse, builder, of Mutley, from the designs of Mr. George Fellowes Prynne, architect, of London and Plymouth. Inclusive of the site, the cost has been about 4,500*l*.

**Birmingham.**—The ceremonial opening of the new work-house infirmary is fixed to take place on January 9 next. The infirmary is one of the largest in the world. The guardians determined that they would erect a plain substantial building, without unnecessary ornamentation, but that it should be fitted up in the best possible known way to insure its efficiency for the work it would be called upon to do. With this end in view they appointed a deputation of four of their number, namely, Mr. E. J. Stout, Dr. Barratt, Mr. Price, and Mr. Jerrett, who, with the architect, Mr. Ward, were instructed to visit any institution in the kingdom they thought advisable, and to "gather up," as it were, all the good things they could find in the way of appliances, fittings, machinery, &c. They accordingly visited a large number of public institutions in England and Scotland, and availed themselves largely of the opportunities given to them for this purpose. The result has been that an infirmary has been erected which, the guardians believe, is one of the most perfect in the kingdom. The cost will be about 85,000*l*. exclusive of the land, which was already the property of the guardians. Some portion of the old infirmary will be joined to the new building, and accommodation will be obtained for 1,700 beds, allowing 1,100 cubic feet of space for each bed, and 2,400 feet per bed at the infectious block.

### CHURCH BUILDING AND RESTORATION.

**Strathpeffer, N.B.**—A new church for the use of the members of the Established Church and the large number of visitors who annually visit the parish is to be erected at Strathpeffer. Plans have been prepared by Mr. Jones, architect, of a building capable of accommodating 600 persons, and these have been adopted by the Presbytery. The church, which is to be erected on a site in front of Kinnetas House, will cost 2,500*l*. or upwards. Grants have been promised from the Baird Trust, the Highland Committee, the Home Mission Scheme, and friends of the church. The erection of the church will, it is expected, be commenced early in the new year.

### GENERAL.

**Mr. Milo Griffith** was the designer of the silver shield presented by the people of South Wales to the Prince and Princess of Wales in commemoration of their silver wedding.

**The War Office** authorities have purchased several acres of ground situated between Epping and Ongar, as a site for the erection of military barracks. The spot selected is on high land, only a short distance from the Ongar branch of the great Eastern Railway. The barracks will provide accommodation for five thousand men, and the work of erection will commence immediately after Christmas.

**A Bridge** is to be constructed across the river Danube in connection with the Fetesci-Cernavoda Railway. The plans have obtained the sanction of the Roumanian Minister of Public Works.

**The Architect** employed to repair Seville Cathedral reports that the condition of one if not more of the pillars justifies serious alarm for the safety of a large portion of the edifice. Energetic measures are being adopted to shore up the faulty pillars.

**A Theatre** is about to be erected on the site of the old Gaiety Theatre, Douglas, Isle of Man, for Mr. James H. Elphinstone, from the designs of Mr. John Taylor, architect, of Longton, Staffs.

**A New Lecture Hall** has been erected at Sunderland, and special attention has been paid to the ventilation, which is carried out on Messrs. Boyle's system, the extraction of the vitiated air being effected by the latest improved form of the patent self-acting air-pump ventilator, and fresh air admitted through their improved air inlets.

**A Preliminary Plan** for the erection of a public hall and hotel at Montrose has been laid before the Town Council. The cost of the buildings is roughly estimated to be between 12,000*l*. and 15,000*l*.

**The Parish Church of Wistaston, Cheshire**, has been redecorated and the sanctuary provided with a new reredos, sedilia, wainscotting, and mosaic floor. Mr. John Brooke designed the work.

**A Site** for the proposed cottage hospital at Forres has been acquired. The subscription fund at presents amounts to nearly 2,500*l*.

**The Blake Memorial**, a stained-glass window placed in the north aisle of St. Margaret's Church, Westminster, was unveiled on Tuesday.

*Special arrangement may be made for a series of insertions on application to the Publisher, P. A. GILBERT WOOD, 175 Strand, London, W.C.*

### TENDERS, ETC.

As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 p.m. on Thursdays.

Correspondents, when writing to notify an extension of time, or an alteration of the date of sending in Competitions or Contracts, are requested in their letter of advice to write at the head of the required change—"Contract Reporter to THE ARCHITECT."

### EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

### COMPETITIONS OPEN.

"THE GOLD MEDAL RANGE."  
WORKS, ROTHERHAM. Estab. 1854.

after considerable alterations and improvements in the interior. Amongst others may be mentioned a handsome brass eagle lectern, which, with chancel standards and other articles, has been presented by a wealthy parishioner. The work was entrusted to Messrs. Jones & Willis, of Birmingham and London.

MESSRS. J. & C. CHRISTIE, of Mansell Street, have executed the plumbing and sanitary work, the fire-mains, and the gallery guard-rails in the new Lyric Theatre.

MESSRS. PITMAN & SON, of Newgate Street, have just completed a large oval-shaped stained-glass window for the chapel of the Poor-house of the City of London Guardians, Homerton. The inscription, "O worship the Lord in the beauty of holiness," is prominent around the outer edge; in the centre is the sacred monogram, with foliage, fruit, &c. It forms an appropriate addition to the important window, "The Good Shepherd," which Messrs. Pitman & Son were commissioned to provide last year, for the same building, in commemoration of Her Majesty's Jubilee.

THE Insanitary Property and Artisans' Dwellings Committee of the Liverpool Town Council have recommended that the Council place at their disposal the sum of 7,600*l.* for the erection of labourers' dwellings, and the sum of 14,000*l.* for the purchase of insanitary property.

THE extension of the works of the Leeds Steel Forge Company, Limited, a new company until recently carried on by the Airedale Steel and Hematite Iron Company, Hunslet, Leeds, is being pushed forward. It is anticipated that by the first week in January the managers of the new enterprise will be able to commence turning out best steel by the basic process. For the purpose of the extension a considerable quantity of land adjoining the old works has been acquired.

GROUND at Clydebank has been staked off by the contractors, Messrs. Hunter & Kerr, Glasgow, for three blocks of dwelling-houses and shops on the south side of the Glasgow Road, opposite Hamilton Place. The tenements are to be three storeys in height, and are the first instalment of twelve or thirteen blocks that are to be built there, and which will give accommodation to eighty or ninety families. The new block of buildings being erected at the foot of Kilbowie Road is nearing completion.

At a meeting of property owners of Northwich held on Tuesday, it was resolved to present a memorial to Parliament asking for the appointment of a Royal Commission to inquire into the injuries inflicted upon property, roads, sewers, gas and

water-pipes of the district by the subsidence resulting from brine-pumping, and to ask for compensation for damage done. Northwich is in a terribly dilapidated state, and the sinking of the public streets threatens to bring the town below the level of the river.

A BILL is to be promoted in Parliament for additional powers for the Bridlington Local Board with reference to the Sea Wall Parade, and the transfer of the existing rights of the lord feoffees of the manor.

A LANDSLIP has befallen the Queen's Parade at Scarborough immediately above the undercliff which the Corporation are transforming into pleasure grounds on the North Cliff. It is feared that the accident will necessitate extra expenditure of money.

A STAINED-GLASS window, in memory of the late Archbishop Strain has been unveiled in the Roman Catholic Chapel, South Queensferry, Edinburgh. The work has been executed by Messrs. Barnett & Son, of Leith.

A MONSTER blast by mining has been effected at Furnace Granite Quarry, Lochfyne Side, of which Messrs. Sim & Co., granite merchants, Glasgow, are the lessees. The mine was bored through the solid rock at a height of 45 feet above the quarry floor. From the mouth or entrance it ran in an easterly direction 59 feet, and at this point sank straight downwards to a depth of 12 feet, and from thence it ran in a north-westerly direction 36 feet, when it reached a chamber in which there were deposited 10,525 pounds, or nearly five tons, of gunpowder. The chamber measured 7 feet in length, 5 feet in breadth, and 5 feet in height. The whole length of the bould rock measured 114 feet, and the rock resting immediately above the chamber was 150 feet. The blast was successfully exploded by means of an electric battery, when about 75,000 tons of granite of fairly good quality were displaced.

THE tender of Mr. Joyce, of Whitchurch, has been accepted for the erection of a new clock in St. John's Church, Coventry. There was a large number of tenders, and those of Mr. Potts, Leeds, and Mr. Gillett, Croydon, ran very close to the accepted tender.

COMPLAINTS have been made as to the nuisance created by the intercepting depôts at Howley and Battersby Lane district, Warrington. The Sanitary Committee and Mr. Longdin, borough surveyor, have just been conducting experiments at the Howley depôt with the object of mitigating, if not entirely abating, the evil. It is claimed that the experiments have been attended with success. The operation consists in the foul air

being drawn by means of a fan through a series of pipes into a large tank containing disinfectants. The air having been purified passes out of the tank, the only smell being that of carbolic.

THE Government surveyor from Edinburgh has been inspecting various sites at Paisley for the erection of a new general post-office. The present post-office was built about ten years ago at a cost of 8,000*l.*, but is now insufficient to meet the needs of the town.

CONTRACTS for a second series of private street improvements at Horwich have been signed by Mr. Cowburn, of Hindley, and Mr. Unsworth, of Earlstown. Upwards of twenty streets will be dealt with under the two contracts, the cost being about 2,300*l.* The first series of street improvements were let to Mr. W. Pollitt, of Bolton.

MESSRS. MANLOVE, ALLIOTT & CO. notify a change in their London address after Christmas from 50 Queen Victoria Street, E.C., to 276 Winchester House, Old Broad Street, E.C.

MESSRS. JOHNSON BROS., of Birmingham and 21 Warwick Square, Paternoster Row, E.C., have brought out a new series of "Planet" pens and "Acme" pens of excellent quality, which for the convenience of purchasers can be had in sixpenny or shilling boxes as well as in gross boxes. The way in which the boxes and labels are got up is creditable, and in keeping with the good quality of the pens contained in them.

THE annual meeting of the Dundee and District Plumbers' National Registration was held in the Guild Hall, Dundee, on Saturday. The secretary, Mr. Farquharson, reported that examinations in practical work prior to registration had been held in various towns, and of 57 candidates 47 satisfied the examiners of their practical efficiency. The Company of Plumbers had presented certificates to 38 masters and 105 operatives in the district.

#### NOTES ON NOVELTIES.

Messrs. Corfield & Morgan, of Cardiff, have recently introduced a novelty to the London market, which ought to find favour amongst a large section of our readers. It consists of a combination of marble mantel and overmantel and mirror, giving a uniformity of effect which is both fresh and artistic. In the ordinary way a mantelpiece was surmounted by a wood

overmantel, with mirror, but we think it does not give a perfect relief to the furniture, as this complete combination of Messrs. Corfield & Morgan's, in which is seen harmony of colour and brightness. Again, there is much more scope for design in the latter in the way of pretty pillars, brackets, and projections, which seems to have been realised by the firm in many of their excellent specimens. This innovation might suggest to architects designs for the manufacturers to copy. Messrs. Corfield & Morgan apply the same principle in slate mantels and overmantels in imitation of griote, malachite, Sienna, serpentine, and other marbles, to such purpose that they can be scarcely distinguished. The quality of the work is especially noticeable in its high finish and variety of design, in which connection we should add that Messrs. Corfield & Morgan import their marble direct, and use their slate direct from the quarry, and in both instances they are chiselled and modelled by the most skilled men, and worked from raw slabs into the artistic specimens of mantels and overmantels. The material used is solid, thick, and durable, as distinguished from much of the cheap imported work. We understand that specimens of Messrs. Corfield & Morgan's combination mantel and overmantel can be inspected in London at Adams's emporium, 67 Newington Causeway, S.E.

#### THE REVALUATION OF THE METROPOLIS.

THE totals of the gross and rateable values of the parishes and unions of the metropolis, to come into force on April 6 next, have just been compiled by Mr. Jebb, the officer appointed under the Act of 1869 (Valuation of the Metropolis), and show an increase of gross value from 37,704,434*l.* last April to 38,028,506*l.*, and of rateable value from 30,975,672*l.* last April to 31,244,495*l.* The increase is not constant over the metropolis, but values have, as a rule, been fairly maintained, and the places which will be assessed at less value are undergoing changes which, for the most part, will lead to higher assessments in times to come.

The highest assessment of any place, parish, or union is the Union of the City of London, and the 112 parishes, precincts, and inns, from the boundaries of Westminster, at the Griffin, Fleet Street, to Aldgate, and from the Thames to St. Giles, Cripplegate, within the City give a total of 4,598,907*l.* gross value as the next assessment, as against 4,556,252*l.* of the present assessment, and a rateable value from next April of

FOR HAND, GAS, AND STEAM POWER.  
THOS. THOMAS & SONS, Acme Hoist Works, CARDIFF.

3,822,571 $\frac{1}{2}$ , as against the present assessment value of 3,792,020 $\frac{1}{2}$ . The Middle Temple and Inner Temple, though forming no part of the City of London Union, are assessed by the committee of the Union, and these places show, in one instance—that of the first-named—an unchanged assessment of 18,608 $\frac{1}{2}$  gross and 15,491 $\frac{1}{2}$  rateable, the same as last year; and the latter is 27,122 $\frac{1}{2}$  gross and 22,697 $\frac{1}{2}$  rateable, as against 27,146 $\frac{1}{2}$  gross and 22,717 $\frac{1}{2}$  rateable of the present year. The other places of the metropolis are taken in alphabetical order, and the comparison of the current year values will show the increase or decrease. Bethnal Green parish will have next year a total rateable value of 403,378 $\frac{1}{2}$ , as against 401,609 $\frac{1}{2}$  this year. The parish of St. Giles's, Camberwell, will have a total rateable value of 1,028,652 $\frac{1}{2}$ , as against 1,016,544 $\frac{1}{2}$ . St. Luke's, Chelsea, will have a rateable value of 629,804 $\frac{1}{2}$ , as against 625,309 $\frac{1}{2}$ . St. John's, Hampstead, will have a rateable value of 620,240 $\frac{1}{2}$ , as against 595,476 $\frac{1}{2}$ . St. Mary's, Islington, will have a rateable value of 1,639,621 $\frac{1}{2}$ , as against 1,631,843 $\frac{1}{2}$ . St. Mary Abbott's, Kensington (gross value 2,269,253 $\frac{1}{2}$ ), will have a rateable value of 1,902,163 $\frac{1}{2}$ —the largest assessment of any one parish—as against 1,876,043 $\frac{1}{2}$  of this year. St. Mary, Lambeth, will have a rateable value of 1,490,965 $\frac{1}{2}$ , showing a decrease from 1,491,123 $\frac{1}{2}$ . The hamlet of Mile End Old Town will have a rateable value of 367,573 $\frac{1}{2}$ , a decrease from 367,793 $\frac{1}{2}$ . St. Mary, Paddington, will have a rateable value (decreased) of 1,274,807 $\frac{1}{2}$ , as against the present rateable value of 1,276,607 $\frac{1}{2}$ . St. Leonard's, Shoreditch, will have a rateable value of 644,246 $\frac{1}{2}$ , as against the present value of 642,133 $\frac{1}{2}$ . St. Marylebone will have a rateable value of 1,433,617 $\frac{1}{2}$ , against the present assessment value of 1,433,029 $\frac{1}{2}$ . St. Pancras will have a rateable value of 1,559,744 $\frac{1}{2}$ , a slight decrease from 1,560,633 $\frac{1}{2}$  of the present year. St. George's-in-the-East will have a rateable value of 188,638 $\frac{1}{2}$ , as against 185,292 $\frac{1}{2}$ . The Union of St. Giles's-in-the-Fields (gross 208,818 $\frac{1}{2}$ ) and St. George's, Bloomsbury (gross 174,176 $\frac{1}{2}$ ), will have a combined rateable value of 382,944 $\frac{1}{2}$ , as against 380,763 $\frac{1}{2}$ . Lincoln's Inn is separately assessed at 21,149 $\frac{1}{2}$ , as against 19,608 $\frac{1}{2}$ . St. George's Union (St. George's, Hanover Square, St. Margaret's and St. John's, Westminster, and the Close of the Collegiate Church of St. Peter, Westminster) will have a rateable value of 2,444,026 $\frac{1}{2}$  (gross 2,932,688 $\frac{1}{2}$ ) as against the present rateable value of 2,433,200 $\frac{1}{2}$ . The Fulham Union (Fulham and Hammersmith) will have a rateable value of 881,335 $\frac{1}{2}$ , as against 863,485 $\frac{1}{2}$ . Greenwich Union (including both the parts of St. Paul's, Deptford, in Kent and Surrey, and St. Nicholas, Dept-

ford) will have a rateable value of 762,340 $\frac{1}{2}$ , as against the present rateable value of 743,754 $\frac{1}{2}$ . The Hackney Union (Hackney and Stoke Newington) will have a rateable value of 1,131,880 $\frac{1}{2}$ , as against 1,121,693 $\frac{1}{2}$ . The Holborn Union (including the parishes of St. Andrew-above-Bars, St. George the Martyr, Furnival's Inn, the part of St. Sepulchre in Middlesex, Saffron Hill, Hatton Garden, Ely Rents, Staple Inn, the parishes of St. James and St. John, Clerkenwell, St. Luke, Middlesex, and the Charterhouse) will have a rateable value of 1,032,699 $\frac{1}{2}$ , as against 1,016,285 $\frac{1}{2}$ . Gray's Inn will have an unchanged rateable value of 16,067 $\frac{1}{2}$ . The Lewisham Union (Lee, Eltham, and Lewisham) will have a rateable value of 657,062 $\frac{1}{2}$ , as against 652,579 $\frac{1}{2}$ . The Poplar Union (St. Mary, Stratford, All Saints, Poplar, and St. Leonard, Bromley) will have a rateable value of 665,025 $\frac{1}{2}$ , showing a decrease from the present value, 673,397 $\frac{1}{2}$ . St. Olave's Union (St. Thomas, Southwark, St. Mary Magdalen, Bermondsey, St. Olave, Southwark, St. John, Horselydown, and St. Mary, Rotherhithe) will have a rateable value of 790,377 $\frac{1}{2}$ , a decrease from the present 805,096 $\frac{1}{2}$ . St. Saviour's (Southwark) Union (Christ Church) St. George the Martyr, St. Saviour's, and St. Mary, Newington, will have a rateable value of 1,044,087 $\frac{1}{2}$ , as against 1,041,942 $\frac{1}{2}$ . The Stepney Union (St. Paul's, Shadwell, the Hamlet of Ratcliffe, St. Ann's, Limehouse, and St. John's, Wapping) will have a decreased rateable value of 303,315 $\frac{1}{2}$ , as against 303,746 $\frac{1}{2}$ . The Strand Union (St. Martin's-in-the-Fields, St. Paul's, Covent Garden, the Precinct of the Savoy, St. Mary-le-Strand, St. Clements Danes, and the Liberty of the Rolls) will have a rateable value of 859,636 $\frac{1}{2}$ , as against the present rateable value of 834,656 $\frac{1}{2}$ . The Wandsworth and Clapham Union (including Clapham, Tooting Graveney, Streatham, St. Mary's, Battersea, Wandsworth, and Putney) will have a rateable value of 1,645,539 $\frac{1}{2}$ , as against 1,598,197 $\frac{1}{2}$ . The Westminster Union (St. Anne's and St. James's) will have a rateable value of 825,213 $\frac{1}{2}$ , as against 819,703 $\frac{1}{2}$ . The Whitechapel Union (including the Precinct of the Old Tower Without, the Holy Trinity, Minorities, Liberty of the Old Artillery Ground, the Hamlet of Mile End New Town, St. Mary's, Whitechapel, Liberty of Norton Folgate, St. Botolph Without, Aldgate, the Precinct of St. Katharine, and Christ Church) will have a rateable value of 385,831 $\frac{1}{2}$ , as against the present rateable value of 379,992 $\frac{1}{2}$ . The Woolwich Union (Charlton, Kidbrooke, Woolwich, and Plumstead), will have a rateable value of 346,712 $\frac{1}{2}$ , as against 339,818 $\frac{1}{2}$ , the present rateable value.

## CONTRACTORS TO H.M. GOVERNMENT.

INTERNATIONAL HEALTH AND OTHER EXHIBITIONS—MEDALS AWARDED FOR

# LEGGOTT'S PATENT ADJUSTMENT

CONTINUOUS OPENER.

SILENS.

THE SILENS, for Fanlights, Skylights, &c. is admitted to be the best ever put before the Public. Can be adapted to any kind of window. Size and height of window no object.

From 4/3 each.

The WILMOS is worked with a rod or endless cord. It is extremely neat, and can be fixed to open either top or bottom, inwards or outwards; no cutting away of frame required. When worked with a rod is most efficient for Public Buildings, as the key can be loose. For Price Lists Illustrations, and Testimonials, write as below.

For Continuous and other Lights, Estimates given.

WILMOS.

NO CUTTING AWAY OF FRAME REQUIRED.

### TESTIMONIAL.

SIRS,—I have pleasure in testifying that I have used Leggott's Silens Adjustments for various buildings to high skylights, fanlights, and top parts of windows, and in every case they gave satisfaction.

They are secure in whatever position, whether the window is open or closed, and are quite simple and workable in their action. I prefer them to any other that I have seen or used for the above-mentioned purposes.

Messrs. W. & R. LEGGOTT, Bradford.

I remain, yours obediently,

R. DAVIES Architect.

BANGOR: N. Wales: Sept. 14, 1885.

Considerably Reduced Price List, November 1, 1887.

ALL WORK ENTRUSTED TO US GUARANTEED SATISFACTORY.

W. & R. LEGGOTT, General Brass and Ironfounders and Finishers, Makers of Patents and Specialties.

235 HIGH HOLBORN, LONDON, W.C.;

109 HOPE STREET, GLASGOW; SILENS WORKS, BRADFORD.

TELEGRAPHIC ADDRESSES—"SILENS BRADFORD"

The totals of 38,028,506*l.* gross value of the metropolis from April 6 next, and 31,244,495*l.* rateable, may be contrasted with the like figures in the first year of the present decennial period, 1881, when the totals were—gross, 33,204,519*l.*, and rateable, 27,402,509*l.* In the first year of the previous decennial period, 1871, the figures were—gross, 24,176,338*l.*, and rateable, 19,900,072*l.* The metropolis thus is shown to have increased from less than 20,000,000*l.* in rateable value to more than 31,000,000*l.* in the eighteen years, and by more than 14,000,000*l.* in gross value in the same period.

#### ELECTRIC LIGHTING IN THE INNER TEMPLE.

A PETITION to the treasurer and benchers of the Inner Temple is being extensively signed by the members of that Inn against the extensive works at present in progress, in the Inner Temple Gardens, in connection with the installation of the electric light in the Inner Temple. The petitioners point out, among other things, that the erection of the engines, dynamos, and works in the Inner Temple Gardens will not only seriously depreciate the value of the chambers in the vicinity, but will constitute a permanent eyesore and disfigurement to the gardens. The petitioners, therefore, pray that if the extension of the electric light in the Inner Temple cannot be carried out except at such a sacrifice, the scheme be forthwith abandoned.

#### LIVERPOOL THEATRES.

At a meeting of the justices of the peace for the city of Liverpool, which was held on Monday, Sir James Picton, who was chairman, explained the action that the bench had taken for the purpose of having precautions provided in the local theatres for the safety of the public. The sub-committee appointed by the magistrates, after visiting the theatres, recommended that certain rules and regulations should be observed by the lessees and others in charge of such buildings, and the licenses were only renewed when those rules and regulations had been to a large extent complied with. The bench recommended the watch committee to appoint an inspector to visit the theatres so as to ensure the carrying out of those rules and regulations, more especially with regard to fireproof curtains and iron doors between the stage and auditorium.

It was reported that the head-constable did not consider that police-inspectors possessed the qualifications for the duties which would be imposed on them by the magistrates, and that the duties would be more than would fill up the whole time of a duly qualified man.

The Chairman remarked that the matter was of such importance that, although it would only be temporarily in their hands, precautions ought to be taken so that perfect arrangements might be handed over to their successors. He had sketched out a resolution, which he would move, viz.:—"At a meeting of the city justices, held on December 17, 1888, the correspondence between the law clerk and the head-constable on behalf of the watch committee having been read, it was resolved that, in the opinion of this bench, it was essential for the safety of the audiences attending the theatres that the precautions and regulations prescribed by the magistrates should be carried out under police inspection; and the attention of the watch committee to the subject is earnestly requested."

Mr. Meade-King thought the justices should in some way or other define what were the rules and regulations which the police-inspector was to observe. It seemed to him that the controversy which the correspondence disclosed arose out of a misconception of what these rules and regulations were. The head-constable stated that no ordinary policeman could possibly superintend the duties expected of him, and he (Mr. Meade-King) contended that the task would be of the simplest possible character.

The Chairman said that, if the watch committee repudiated all responsibility, the magistrates had no power to incur expense. The whole thing would then fall to the ground.

Mr. Patterson: Who will have the power of making the rules after April 1 next?

The Chairman: I presume the county council will.

Mr. Patterson considered that the power was in the hands of the police to see that the rules were carried out, and he saw no reason why the letter addressed by Mr. Ellis to the head-constable, together with Sir James Picton's resolution, should not be sent to the watch committee and await the result. The watch committee would have the whole matter in their charge from April 1 next, and they might as well look a little ahead. He regretted that action had not been taken before. There was one theatre underneath which were a stable and warehouse, separated from the auditorium only by the floor, in which a quantity of hay and straw and some ponies were kept.

The Chairman: To what theatre do you allude?

SAMPLES AND LIST FREE ON APPLICATION.

Mr. Patterson: The one in Paradise Street, if I remember right.

The Chairman: There was a wall carried down there. What may be under the floor of the theatre I don't know.

Mr. Patterson supposed there was some guarantee given to the committee that the ponies would be taken away, but somebody ought to see that the place was not used in a way eminently dangerous. That was the reason he believed the police could look better after the matter than any one else.

Mr. Billson seconded the resolution.

Mr. Behrend drew attention to the near approach of the pantomime season, and said something ought to be done in the matter quickly, owing to the large crowds that always visited the theatres at such a time.

The motion was afterwards carried unanimously.

### THE QUEEN ANNE MANSIONS.

ON Friday, counsel for Mr. James Knowles, architect, who resides in a house known as Queen Anne's Lodge, St. James's Park, moved for an order to commit Messrs. Lucas & Aird, contractors, for contempt of Court. The case arose in connection with the action Knowles *v.* Queen Anne and Garden Mansions Company, Limited, the defendants being the owners of the fee simple of Queen Anne's Lodge. The company were engaged in carrying out a scheme to extend the existing Queen Anne's Mansions by pulling down Garden Mansions and erecting new buildings of a great height. The plaintiff complained that these operations were calculated to cause, and in fact had already caused, considerable damage to his house, by depriving it of the support which it had hitherto enjoyed, and also by reason of the interference with the access of light. He, therefore, moved for an injunction to restrain the defendants, their contractors, agents, and servants, from pulling down or weakening or interfering with the wall separating his house from the defendants' premises or in any way depriving such wall of its present support, or making any openings in the wall or otherwise causing damage to Queen Anne's Lodge, and from erecting or continuing to erect any buildings so as to obstruct or interfere with the access of light to Queen Anne's Lodge. The case has been before the Court on several occasions, but from time to time, on the application of the parties, it has stood over. On November 26, Messrs. Lucas & Aird gave an under-

taking, following upon one previously given by the company, not to pull down or weaken or interfere with the wall in question, nor in any way deprive such wall of its then present support, nor make any opening in the wall or otherwise cause damage to Queen Anne's Lodge by their building operations. Since that date the plaintiff alleged that the contractors had, notwithstanding their undertaking, continued to carry on the building operations by excavating the soil adjacent to the plaintiff's wall, and had so brought about a settlement of the wall and caused serious cracks to appear therein. The plaintiff then moved for an order for commitment. The evidence, which consisted to a great extent of affidavits by surveyors and architects, was very conflicting; that on behalf of the defendants being to the effect that the building operations had been carried out with the utmost care, having regard to the safety of the plaintiff's house, and in fact that its stability had not been in any way injured; that the cracks in the wall were not of recent origin, the house being a very old one, but had probably been caused by the vibration of the trains upon the District Railway, which runs in close proximity to the plaintiff's house, or by some cause other than the building operations. The defendants also alleged that the plaintiff had refused to allow his wall to be underpinned, and therefore they had been obliged to construct the foundations of their buildings in short sections, excavating the soil and filling up the holes thus made with concrete and brickwork as they went along. It appeared that, after the undertaking given by the contractors, they had, acting under the advice of an engineer whom they had consulted, continued the making of the holes and filling them up as described, their opinion being that by so doing they were not breaking the undertaking not to deprive the wall of its support. At the commencement of the case the defendants' counsel gave an undertaking as to the interference with the plaintiff's right to light, which was accepted by his counsel. The defendants also, at the suggestion of the learned Judge, agreed to give an undertaking not to make more than one hole at a time, each hole to be of a stipulated size and to be filled up as soon as excavated in the manner described.

Mr. Justice Stirling after stating the facts and alluding to the evidence, said that it was so conflicting that he should not have been prepared to decide the case upon it without some further assistance from experts. The question was whether the plaintiff was likely to suffer any serious injury, and if the defendants were restricted by the proposed undertaking it did not seem that any serious damage could accrue

to the plaintiff's house; while, on the other hand, if he were to grant the injunction asked for, he might seriously hamper the defendants in the operations which they were carrying on upon their own land. Under the circumstances, he thought he ought not to make any order upon the principal motion. There was another point as to the pulling down of a cross wall, which, it was alleged, robbed the plaintiff's wall of its support. As to that, he thought the evidence was not such as to justify his interference. He had still, however, to dispose of the motion to commit the contractors for breach of their undertaking not to deprive the wall of its then present support. His lordship considered the evidence on that point, and referred to the affidavit of the gentleman whose advice the contractors had taken, and who did not go so far as to say that what had been done after the undertaking had had no effect upon the supports of the wall, but only said that it did not deprive the wall of any support which was "in the least degree necessary" to it. That was not enough to clear the contractors. They were an eminent firm, and had filed evidence in explanation of what they had done, and stating that if they had broken the undertaking they had done it in good faith and inadvertently. His lordship was willing to accept their statement. Nevertheless, it must be clearly understood that such undertakings were sacred and to be obeyed to the letter. Under the circumstances, therefore, he must order them to pay the costs of the action.

#### ELECTRICITY AND ARTESIAN WELLS.

THE discharge of water from artesian wells has for many years been employed as a motive power in France. In the city of Tours there is an artesian well which drives a hydraulic wheel seven metres in diameter, and works the machinery of a silk factory. At Grenelle the heat of the water issuing from a deep well is utilised in warming buildings. A project is now before a Commission of the Municipal Council of Paris having for its aim the utilisation of the power obtainable from the new artesian well in the Place Hébert, at La Chapelle. There are now three important artesian wells in the Paris basin; that of Grenelle being the oldest, and that at Passy the most productive. The new La Chapelle well is, however, situated in an industrial quarter of the eighteenth arrondissement, and is thus well adapted for the experiment of producing motive power. Besides these there are a number of private artesian wells in Paris belonging to manufacturers. The La Chapelle well was

finished in March last, having been begun twenty-four years ago. It reaches a depth of 720 mètres, and the water, left to itself, rises to a height of 35 mètres above the mouth. It furnishes 6,000 cubic mètres of water in twenty-hour hours. The proposal is to utilise the power furnished by the well in generating and distributing electricity for lighting and motive purposes. One object mentioned is the lighting of the park of the Buttes Chaumont, which is situated near the well. Before now electricity has been generated in this manner. At Ponce de Leon, in Florida, there is an hotel having a powerful artesian well, which drives a turbine-wheel and dynamo, thus generating the current necessary to light the building and its grounds. At Yankton, in Dakota, there is a flowing well which drives the dynamos of an electric light company. The well is 600 feet deep, and the water on issuing from it is conducted to a reservoir placed 30 feet above the turbine which actuates the dynamos.

#### TECHNICAL EDUCATION.\*

MOST people seem to be agreed that some sort of technical education is necessary, but they are not at all in accord as to what form this education should take. Many of them, I think, consider that the multiplication of science colleges is all that is wanted; these may do well for the higher class of students who have already received a moderately advanced education, but for all the ordinary purposes, for technical education as I have described it, that is to say, as a preparation for the lifework of 99 per cent. of individuals, they are practically useless; even in the case of the remaining 1 per cent. I think they fall short of what is requisite and especially in workshop practice. I do not think that the workshops attached to these establishments are of much value, except when considered as testing rooms; the work done must necessarily be amateurish, for it is not done for commercial purposes; the objects worked at are frequently old-fashioned and out of date, and thus the knowledge gained is of little value. I believe that it would be far preferable that these colleges should be affiliated to large workshops, in which, and in which only, a thorough knowledge, such as is aimed at, can be obtained. The advantages might be made reciprocal, so that, whereas the pupils at the college were

\* From the presidential address delivered before the Civil and Mechanical Engineers' Society by Mr. Middleton.

## IMPORTANT NOTICE.

**MESSRS. T. F. PINNOCK & CO.**  
**ART-METAL WORKERS,**

Will appear in Special Issue  
of January 4.

80<sup>1</sup>/<sub>2</sub> HORSEFERRY ROAD,  
WESTMINSTER,  
LONDON, S.W.

able to visit the works, so also the draughtsmen, foremen and men from the works might visit the college and attend evening lectures there.

I firmly believe that every engineer, whether he intends to follow the civil or mechanical branches of his profession, should spend a reasonable time in the shops of some large works; and if this is true of the engineer, how much more true must it be of the men who have to pass their lives and earn their livelihood in such works? and this brings us to the question of what is the best form of technical education for the men.

Professor Huxley says, and I fully agree with him, that we are not likely to hit off a perfect scheme at once, but that we can only arrive at some approach to perfection through much blundering; he goes on to say that consistent error is very often vastly more useful than muddle-headed truth, and I think we have all had experience of the accuracy of this statement. Let us hope, nevertheless, that the scheme of education, whatever it is, may approach as nearly as may be to consistent truth.

Let me give you a few facts and figures from a pamphlet by Mr. Alfred Harris on "Industrial Art Teaching and the System of Progressive Schools in Germany."

Mr. Harris says that what we want in this country are progressive schools such as are in use in Germany, the district to which he specially refers being Würtemberg. He contends that we have primary schools and science colleges, but no intermediate education, nothing which will enable the boy who leaves the Board school at the age of twelve or thirteen to continue his education voluntarily up to a time when he might be fitted to enter a science college, or to such an extent, at any rate, that when he had reached the age of sixteen or seventeen he would know more, not less, than when he was ten.

In Würtemberg one such school numbers 300 students, the total expenses being 695*l.*, or 2*l.* 6*s.* 4*d.* per student. Of this sum 116*l.* is provided by the students themselves, and the balance of 579*l.* is borne half by the municipality, and half by the central department.

The subjects taught are:—Geometrical and freehand drawing in its more advanced stages. Careful and correct modelling in wax or clay from well-selected models. Sketching from natural objects and casts, figure drawing from models, ornament and still life, and original design, these being the requirements of the industry which flourishes where the school is situated; payment is not made by result, but the teachers have fixed salaries.

The government of the industrial system is of a paternal character. The central department at Stuttgart is composed of a president, with administrative and technical officers who conduct the general business. They are assisted when required by the teachers in various institutions, and by representative counsellors, merchants, manufacturers, &c., chosen every four years by the Chambers of Commerce in the provincial centres.

Although the Central Department of Industry is supported by the State, it acts rather as an intermediate authority between the industries of the country and the Government than as a bureaucratic department. Its officers are in close touch with the trade organisations of the country on the one hand, and with the higher departments of the Government on the other.

The department acts upon the principle that more is to be gained by practical assistance in the development of industry than by *theoretical instruction*.

There are in Würtemberg, which has a population of 2,000,000, about 690 of the evening classes such as have been described, besides 906 schools and classes for agriculture, with an attendance of 21,000, and 82 agricultural reading-rooms with over 3,000 members.

Mr. Harris maintains that many industries which had almost died out have been revived and made into flourishing businesses by the help of these schools.

Mr. Swire Smith, one of the Commissioners on Technical Instruction, says, in his pamphlet on Technical Education and Foreign Competition:—"The systems of education on the Continent vary in details, but in the leading countries the schools rise in well-defined steps from the lowest to the highest, each grade preparing the student for the next above. Drawing is taught universally, and modelling in most of the French and Belgian schools. The elements of science are taught in Germany and Switzerland, and many pupils in elementary schools throughout France and other countries receive workshop instruction. The whole system is harmonious, elastic, and capable of modification at every step. By the teaching of drawing and modelling, elementary science, and manual occupations, the boys and girls are interested in the development of their skill as a means of obtaining a livelihood; their instruction directs them to suitable callings, and a prepared constituency of young men is formed in every town for the technical schools and evening science and art classes which are attended by tens of thousands of students.

"Technical education has taught foreign manufacturers of all kinds how to adapt their goods to the wants of their

## "THE ARCHITECT'S DIARY" FOR 1889.

Specially prepared for the use of **ARCHITECTS, SURVEYORS, and ENGINEERS.**

These Publications contain not only the usual Diary, ruled and printed to a particular form, specially adapted for professional use, but, in addition, an Index, a Note-Book, a Rent and Insurance Register, a Cash Book, and a Ledger, with all the usual diary information, and much special matter referring to the various Architects' and Engineers' Associations; a digest of all the Acts passed last Session; contain also cases decided in the Superior Courts of Justice during the legal year, from November 1887 to August 1888, of interest to the Profession; complete list of Metropolitan Surveyors and Districts, with Official and Private Address; Alphabetical Index to the Practical Statutes, Stamp Duties &c., the whole forming in **ONE VOLUME A COMPLETE SET OF BOOKS for the YEAR.** The Editions are—

No. 12.—One page to a day, size 8½ in. by 5 in., cloth, gilt, 4/6. No. 13.—Two pages a day, size 8½ in. by 5 in., cloth, gilt, 5/6.

## "THE BUILDER'S DIARY" FOR 1889.

Specially prepared for the use of **BUILDERS and CONTRACTORS.**

No. 11.—Two days on a page, ruled and printed to a special pattern; also contains Bill Register, Note Book, Rent, Insurance, and Mortgage Register, Cash Book, Ledger and 130 pages of Tables of great value to all engaged in the Building Trades, in all 460 pages, size 8½ by 5, bound, whole cloth, gilt. Indexed, and paged to end of Diary. Price 4*s.* 6*d.*

"For use in the office of Architects and Builders they are better fitted than any diaries with which we are acquainted."—*The Architect.*

"Messrs. Hudson & Kearns's Diaries need no recommendation save a trial."—*The British Architect.*

"The novel and valuable feature of these Diaries is that each volume forms in itself a complete set of books for the year."—*The Builder.*

"We have used them ourselves throughout the year with much satisfaction, and are glad now to draw attention to the new batch sent us."—*The Building News.*

"The Diaries published by Messrs. Hudson & Kearns are quite unrivalled for convenience and comprehensiveness."—*Building World.*

"These Diaries may be said to have become the Diaries for the professions for which they are issued."—*Illustrated Carpenter and Builder.*

**Sole Publishers, HUDSON & KEARNS, 83 Southwark Street, London.**

customers, and how to lead or follow the constantly changing fashions. Commercial education has been equally useful to merchants and distributors, enabling them, by a knowledge of foreign languages, to come into direct contact and sympathy with producers on the one hand and distant customers on the other, thereby promoting rapid interchange of ideas for mutual advantage. Distributors have learned from remote customers how to make up their wares so as to suit local weights, measures or fancies, and in a hundred ways to gratify the whims of those for whose business they are catering. These matters may seem to be small and unimportant in themselves, but they are sufficient to turn the balance in all cases of choice, other conditions being equal, and we have seen many cases where the refusal on the part of English manufacturers to alter a pattern or style in order to please a customer, and where, through English ignorance of foreign preferences or tastes in matters of detail, large orders have gone to France or Germany which otherwise would have come to England."

On the other hand, Mr. Swire Smith says that on the return of the commissioners to England, after inspecting the schools abroad, they visited competing establishments, and tested the foreign evidence face to face with all the facts in our own country. They obtained undoubted evidence, proving that, in so far as economy of production is concerned, English manufacturers, despite the higher wages and shorter hours of English compared with those of foreign workmen, have nothing to fear. In respect to machinery, organisation, spirit and energy, they believe the foremost place must be given to English employers and operatives, although in respect of these points the rapid progress of our German rivals during recent years shows unmistakably that there must be neither rest nor sleep if we are to maintain our ground. The best machinery is English; in some of the weaving factories even the yarn is English. The superiority of the foreign establishments is not in machinery, but in men; not in natural faculties, but in training. Nor is this superiority confined to solitary and unimportant industries; it applies not only to machine-work but to hand-work, and to the highest branches of almost every manufactured commodity which enters into the domestic service of man. In textiles the attractiveness of the goods is often strikingly apparent as against English competing goods. The designing is more tasteful, the dyeing and finishing more effective, and the superior "selling quality" thus secured is undoubtedly due to the technical training of the designers and dyers, which they have received in splendid schools provided

by legislatures and municipalities for the purpose. The commissioners would hesitate to express this judgment upon the products of foreign manufacturers and artisans were it their opinion alone, but it is evidently the unbiased verdict of the British public, who purchase the foreign manufactures which the commissioners saw produced on British machines, while at the same time similar machines in England are idle and English operatives out of employment, the bread being literally taken out of their mouths, while the capital of the manufacturers is being eaten away by this alarming competition.

Mr. Swire Smith evidently thinks technical education most necessary, but he is not of opinion that our shorter hours are a disadvantage, or that our manufacturers, merchants and men require more than a better training or a better appreciation of the fact that exertion on all sides and greater adaptability are necessary if our trade is to be maintained. It seems to be believed on all hands that one of the first desiderata is the teaching of drawing, both free-hand and geometrical, but particularly the latter, in all schools. Professor Huxley says that a child who has been taught to make an accurate elevation, plan and section of a pint pot, has had an admirable training in accuracy of eye and hand. This is what is sought to be effected by the teaching of drawing, accuracy of eye and hand. Object lessons such as are used in Kindergarten schools, and the use of tools, is also advocated as tending to secure the same end. It is not desired to form trade schools in schools used for general education, but that the system of education should include lessons which will train the hand and eye as well as the brain, and it is contended that such work will be a relief to the pupil; that, as a fact, he will be able to do his bookwork better and to better advantage, and that he will get a training adapted to the requirements of his lifework.

In support of this view, the work done by half timers in the Board schools is illustrated, it being found that, though they do not work half the time of the full timers, the knowledge acquired is very nearly as great as theirs.

I believe that one of the first and greatest desiderata is a knowledge of modern languages. I think that it would be an exceedingly good thing if every male in the country were obliged to learn at least one modern language.

I feel most deeply the want of such knowledge in myself, and what is easily learnt in youth is not by any means so easily learnt in manhood; I also find considerable difficulty in getting

## GRUNDY'S PATENT WARM-AIR VENTILATING FIRE-GRATE.

The novelty, superiority, and advantage of this patent consist in the heating surface being greater than any other Fire-grate introduced to the public. It is very simple in construction, and is made in the form of a Stove, the back of which is semicircular in shape, with gills behind and smoke-nozzle on top, all cast in one piece. The same can be attached to any design of a Register or Stove front. It is very suitable for schools, class-rooms, waiting-rooms, hospitals, offices, dormitories, and dwelling-houses, from the cottage to the mansion. Design and specification post free on application.

### TESTIMONIALS.

9 Victoria Chambers, Westminster, S.W.  
SIR,—I have much pleasure in testifying to the efficiency of your patent warm-air fire-grate. It has been very successful, and given every satisfaction where I have used it.  
Yours, &c., JAMES WEIR, F.R.I.B.A.,  
6 John Street, Bedford Row, W.C.

To Mr. Grundy.  
From Hon. and Rev. G. G. C. TALBOT, M.A., Withington,  
Cheltenham.

DEAR SIR,—You will be gratified to hear that the school is completely warmed by your new grate. It is the most economical and efficient that I have ever seen.  
Mr. John Grundy.

### ACROSTIC.

Just listen, friends, to what folk say  
Of Grundy's patent warm-air grate,  
How with the fresh air channels they  
Not only warm, but ventilate.

Give wondrous heat, burn little coke,  
Require but slight attention paid,  
Unequall'd for consuming smoke,  
No better grates were ever made.  
Do try just one of Grundy's glow,  
You then will all its merits know.

assistants who can speak the language of the country to which it is desired to send them, therefore I know that, though no doubt there has been an improvement in this respect since my school-days, such improvement has been only on a limited scale and has not gone nearly far enough.

I have already said that, in my opinion, merely theoretical teaching would be useless, or nearly so, that it would not tend to produce either good engineers or good workmen; that the teaching, whatever it is, should be directed primarily to fitting the pupil for his lifework, and that a knowledge of at least one modern language and of drawing is essential. If this view of the matter is correct, how is it to be obtained?

Well, my view is that you must begin at the beginning, that the Board schools must give object lessons, not only in the first standard but throughout the course of study, that drawing must be taught, that for workmen the old system of apprenticeship must be reverted to, and that apprentices must be encouraged, and, if necessary, obliged to attend evening classes, where their knowledge of drawing and of construction shall be extended in accordance with the requirements of the industry in which they are engaged. There is a school of this description in Birmingham, which is, I believe, doing good work, and I understand that there are others about the country.

The tendency is almost sure to be for these schools to be at first too scholastic and bookish, and not sufficiently practical; but I think this will come right of its own accord; if not it will have to be set right by the men themselves, for nothing, in my opinion, is so much to be deprecated as simple theoretical instruction without practical illustration.

If it be granted that technical education, an education supplementary to that of the Board or the public school, and though following on from it, more directly connected with the lifework of the pupil, is necessary, who is to provide these schools, and under whose direction are they to be managed? If the example of Würtemberg is to be followed, there would be a central board, the pupils would contribute their small share of the expense, and the rest would be borne, half by the town or village in which the school was situated, and half by the central departments. I very much doubt, however, if it would be wise to follow the lead of any foreign country in this respect; our individuality is different from theirs, and so are our requirements. Central boards are not in great favour here, and I think that the masters and the men, the merchants and the manufacturers, the agriculturalist and the labourer could manage matters between themselves much better than they could be

managed by any central authority, and that if each district were allowed to tax itself to a reasonable extent for this purpose that would be all that is requisite, the rest would come of itself. It may be said that this would throw a heavy burden on municipal taxes, and that a portion of it should be borne by the imperial taxation, but, after all, what is the difference? If such schools as I have spoken of were universal, as they would have to be if they were to be of any use, the tax, whether paid by imperial or local taxation, would fall practically on the same persons and come out of the same pockets, or if this be not quite true it is very nearly so.

Most towns are given up to a large extent to one industry, therefore the schools in that locality would be directed towards giving instruction adapted to the furtherance of that particular industry.

It has been contended that there would be great difficulty in obtaining teachers, but I think this is a mistake: there are thousands of draughtsmen and foremen in London and the country who are much better able to give instruction in technical work than a simple teacher would be, because they know the practical side of it, and who would be very glad to eke out their not too liberal salaries by teaching.

Finally, the view I have taken is that technical education is necessary, that it should begin in primary schools, where drawing and modern languages should be taught and object lessons given throughout the course, that it should be supplemented by an improved system of apprenticeship, with which should be coupled an obligation or very strong encouragement to attend evening classes, in which the teaching of languages should be extended and instruction given in drawing and in such knowledge as is best adapted to the lifework of the pupil, whether he be a clerk, a draughtsman, a mechanic, an agriculturist, or what not. The subject is such a large one, and, to my mind, of such importance, that I must confess to having fallen far short, in these remarks, of the aim which I had set before myself, but I have found it quite impossible in the short space of an address to deal with it fully, and I can only ask your forbearance in this respect. However, if I have succeeded in giving you cause for thought and for examination into this momentous question for yourselves, I have not altogether failed in my object, which, whether I have taken a right or wrong view of the subject, must always be the advancement and well-being of our native country, and especially of the engineering profession in that country, and I am hopeful that extended education may enable the workmen and the neighbouring

### THE DIVER AND THE OCTOPUS.

A PARALLEL case to the one imagined by Victor Hugo in his "Toilers of the Sea" is reported from Wellington, New Zealand. A man named Alexander McGovan, engaged in the harbour improvement works, went down in his diving-dress for the purpose of setting some large blocks under the water in which piles had been previously driven. As McGovan was in the act of placing one of the blocks, he was seized by an immense octopus. The monster fastened on to the piles at the same time. McGovan at first made an attempt to get clear, but the more he fought the octopus the more he found that it was useless, as its grip became stronger. He then wisely desisted, and in a few moments had the satisfaction of knowing that the octopus had released its grasp of the piles. This was no sooner done than McGovan gave the signal to be hauled up. His signals were quickly responded to, and up went the diver with the creature on his back. Its legs measured 9 feet long. McGovan certainly had a narrow escape, and it was only by his discreet quietness that he turned the tables on the octopus.

### PATENTS.

*This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]*

#### APPLICATIONS FOR PATENTS.

17896. Carl Romany, for "Hasp and staple which can be fixed on any door no matter how limited the space." December 7, 1888.

17916. Sidney Nash Castle, for "An improvement in or connected with rustic or other summer-houses or similar

shaped shelters, band-stands, and like structures." December 7, 1888.

17962. John Wilkinson and James Bingham Allott, for "Improvements in destructors, or apparatus for treating refuse." December 8, 1888.

17966. Cecil George Saunders, for "Improvements in scales for use in enlarging or reducing maps, plans, or the like representations." December 8, 1888.

17970. William Lindsay, for "Improvements in the construction of window-sashes." December 8, 1888.

17990. William Blamforth, for "An improved method of securing door-knobs and the like to their spindles." December 10, 1888.

17991. James Duckett and Alfred Duckett, for "Improvements in and relating to water-closets." December 10, 1888.

17995. John Elliott Hewison, for "A compound set square." December 10, 1888.

18038. John Strachan and John Aleflett, for "Improvements in securing sash-lines to sashes and for similar purposes." December 11, 1888.

18042. Alfred Edward Harris and Howard Joseph Luckock, for "Improvements in spring catches for doors." (Complete specification.) December 11, 1888.

18049. James Hume Gibson and William Glazier, for "Improvements in or appertaining to step-ladders, collapsible A-formed supports, and the like." December 11, 1888.

18070. Thomas Arundel Aldridge, for "An improved chimney-pot and ventilator for insuring an upward draught." (Complete specification.) December 11, 1888.

18073. John Ferguson, for "A fireproof ventilating hearth." December 11, 1888.

18139. Howard Pullar, for "Improvements in devices for securing or locking screw-nuts." December 12, 1888.

18155. Herbert Linskill Joy, for "Improvements in ladders and fire-escapes." December 12, 1888.

18177. Henry Richard Gregory and George Macdonald, for "Improvements in the manufacture of filtering material, applicable to the filtration and purification of water, sewage effluents, saccharine juices, alcoholic liquors and other liquids and fluids." December 12, 1888.

18195. Henry Heaton and Wilbraham Knight, for "Improvements in chimney-pots." December 13, 1888.

18204. Anne Proctor, for "The speedy lighting of fires to be called 'The Instant' fire-lighter and kettle-boiler." December 13, 1888.

## PROVISIONAL SPECIFICATIONS ACCEPTED.

14665. Will Whalley Cottam, for "Improved method of flushing water-closets." October 12, 1888.

15420. Frederick Samacraft, for "Improvements in windows and window fastenings." October 26, 1888.

15461. David Burns and James Blyth Cairns, for "Improvements in apparatus for regulating and fixing fanlights, ventilators, casements, mirrors, and other articles of furniture moving on pivots or hinges." October 27, 1888.

15543. Edgar Newton, for "Improvements in the construction of horticultural and other buildings, and ventilation of the same." October 29, 1888.

16113. Peter Evans, for "Improvements in, and in the manufacture of cement." November 7, 1888.

16169. Francis Fryer Abbey and Albert Walshaw, for "An improved chimney-pot for the prevention of down-draughts." November 8, 1888.

16354. Robert Henry Taylor, for "Double cone mixing-machine, for concrete and other purposes." November 12, 1888.

16574. St. John Vincent Day, for "Improvements in ventilators." (Peter Smith Swan, India.) November 15, 1888.

16774. Burton Richard Philippson, for "Improvements in the disposal of sewage." November 19, 1888.

16901. James Smith Naylor, for "Improvements in and appertaining to automatically-closing doors, applicable for preventing the spreading of fire in mills, warehouses, or like buildings." (Marshall Tillotson, United States.) November 21, 1888.

17312. Richard Warwick, for "Improvements in fibrous plastering work, and in materials used for same, and in the manufacture of slabs or plaques in connection with the same trade." November 28, 1888.

## COMPLETE SPECIFICATIONS ACCEPTED.

Notice is hereby given, that all persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the date of the official *Journal*, give notice at the Patent Office on the prescribed form of such opposition.

17326. James Hill, for "Apparatus for opening and closing fanlights and skylights." December 16, 1887.

284. Moses James Adams, for "Improvements in floor tiles." January 7, 1888.

1295. Richard Ridgway Harrison, trading as Loach & Clarke, for "Improvements in devices for opening, closing, and adjusting fanlights, sashes, and the like." January 28, 1888.

1394. Clement John Heaton, for "Improvements in the production of ornamental work for walls, and other surfaces." January 30, 1888.

1587. Carl Gustave Garbe and Kate Ross, for "Improvements in attaching doors and like knobs, and other handles, to their spindles." February 2, 1888.

1884. Richard Muirhead, for "Improved construction and arrangement of apparatus for the separation of liquids and semi-liquids from solids, especially applicable to sewer sludge, slip, slurry, and other like bodies." February 8, 1888.

2272. John Bassett and Francis Napier Seyde, for "Improvements in the construction of fireproof ceilings and partitions." February 15, 1888.

7211. Isaac Thomas Hawkins, for "Improvements in the construction of sewers." May 15, 1888.

16272. Benjamin Holbrook, for "Improvements in ventilators." November 9, 1888.

## PATENTS SEALED, DECEMBER 14, 1888.

11937. Julius Homan, for "Improvements in the construction of fireproof floors." September 2, 1887.

13133. William Phillips Thompson, for "Improvements in stamping or beating machines for moulding artificial stones and the like." (Joseph Winkler, Germany.) September 28, 1887.

16262. Francis Napier Seyde, for "Improvements in metallic lathing or backing for plaster or cement partitions and ceilings." November 26, 1887.

16375. Alfred Dougill, for "Improvements in baths, or combined bath and hot-water tank or cistern." Nov. 29, 1887.

16578. Samuel Green Bennett, for "Improvements in the construction of hoists and lifts." December 2, 1887.

574. William Joseph Balk, for "Improvements in street gullies and traps." January 13, 1888.

8609. Miquel Pinder, for "Improvements in erasers, and in attaching same to pencils and penholders." June 12, 1888.

10706. George Evans, for "Improvements in the construction of window-frames and hanging the sashes." July 24, 1888.

# THE "THOMAS" LAMP.

Lighting Power with  
ordinary London Sixteen-  
Candle Gas, from tests  
taken by Professor Wm.

Foster, M.A., L.R.C.S.

No.		
10.	11.4	Candle-power per foot.
11.	12.5	" "
12.	12.5	" "

These Lamps are made in three  
sizes, Nos. 10, 11, 12.

These Lamps can be obtained through Gasfitters, Ironmongers and  
Merchants. Foreign Orders through Merchants only.

The advantages of this Patent  
over other existing Lamps  
are:—

Small consumption of Gas  
with great Illuminating power.

No possibility of the Burner  
corroding or getting out of  
order, as is the case with other  
generative gas lamps.

The Lamp can be fitted by  
any gasfitter. No fine per-  
forated metal, gauze, or other  
obstructions are used in this  
Patent, as in other lamps which  
are liable to become choked  
through imperfect combustion,  
rendering the lamps smoky and  
useless.

# The Architect.

## THE WEEK

VISITORS to Paris next year will be able to see several examples of panorama painting. The last century will be unfolded on the great canvas which MM. GERVEX and SARGENT have in hand. The fifteenth century will reappear on one which will be devoted to the life of the heroic JEANNE DARC. The latter will be exhibited in a structure in the Avenue Bosquet, which will be, to some extent, a reproduction of the cottage in Domrémy where the Maid of Orleans was born in 1412. The designs have been prepared by M. FRANSQUIN-ARVENT. The paintings will be the work of M. PIERRE CARRIER-BELLEUSE, a son of the late sculptor. He is about to visit Compiègne, Rheims, Domrémy, Vaucouleurs, and the various scenes of incidents in the tragic history of the heroine. By February 1 it is expected the materials will be collected and the sketches completed. The canvas will then be attacked, and if all goes well the panorama will be opened on May 8, the anniversary of the birthday of JEANNE DARC.

THE Munich Academy of Art insists on expedition as a quality for painters and sculptors. The schools were opened in the last week or two, and the subjects for competition are now prescribed. The works must be completed by January 15 of next year. For the painters one subject is assigned, viz. *Evening*, which may be treated as a landscape, as *genre*, or as history painting. The sculptors can take a subject from the legend of PSYCHE, and from it produce a single figure, a group, or a relief.

THE Waterford guardians of the poor are too generous. They have just issued an advertisement in the form of a poster for a plan and specification for a hospital building 100 feet long and 18 feet wide, which are to be submitted to those worshipful gentlemen on or before Thursday next. The documents are to be accompanied by "a statement of the architect's fee," but it is not to be supposed that all the competitors will receive a donation, for the approved plan only will be paid for, and the guardians do not bind themselves to accept any plan. It is rather novel to find designs sought after by the agency of the bill-stickers, as if architects were dust contractors or suppliers of turf or potatoes. Waterford is a stronghold of advanced politics, and so simple a way of doing business without any conventionalities of decorum is an indication of what architects may expect under the coming régime.

THE annual meeting of the Royal Institute of Architects of Ireland was held on Saturday last. Mr. DREW, R.H.A., presided. The report referred to the proposed affiliation with the Royal Institute of British Architects, but the council did not see their way to recommend the step at once. It would be attended with the danger of their Irish Institute losing its identity, and while willing to co-operate with the British Institute in the interests of the profession, the council deemed it better to preserve their independence. In the last report it was stated that should any of the Irish students desire to enter their names for the examinations held by the British Institute, the council would be happy to make arrangements for the examination in Dublin. The report also dealt with the irregularities of the Irish officials, which formed the subject of a correspondence with the departments. The paid officials of the Board of Works and the Local Government Board not only prepare special plans of buildings for private persons, but in some cases they also inspect them, thus taking upon them duties which are entirely outside those for which they receive their salaries, and which properly belong to the practising members of the profession. The Board of Works referred the council to the Local Government Board, and the latter passed them on to the Treasury, and their reply simply amounted to a refusal to make any alteration in the working of the system. The council therefore intend to get the matter brought before Parliament during the coming session. Mr. O'CALLAGHAN said the feeling was very strong against the amalgamation of

the Irish Institute with the Royal Institute of British Architects. They should maintain their individuality, and they had frequent experience of the advantages attending membership of an Institute like theirs in courts of law and elsewhere. Mr. DREW pointed out the necessity of obtaining a Building Act for Dublin, and suggested that as next year the Institute would have reached its fiftieth year, something should be done to mark so interesting an occasion.

UP to Friday last the sales in the Exhibition of the Manchester City Art Gallery amounted to 3,731*l.* 18*s.* As that sum represents eighty-two pictures, the average was not more than 45*l.* This is a lower rate than usual, and, it is to be hoped, is a sign of a temporary depression, and no more.

A CURIOUS case has been decided in the Hamilton Sheriff Court. In 1887 Stevenston House, which was in course of erection, was destroyed by fire. A firm who had undertaken the carpentry and joiner's work claimed for certain extras, as well as for work executed. It appears, however, that they had received written notice that extra work was not to be undertaken unless an order in writing was given. The case was heard at great length, and the Sheriff remitted two questions for report to Mr. MITCHELL, architect, Airdrie. One was whether the plaintiffs were entitled to extras for which written orders could not be shown, and the second was whether they were entitled to be allowed for woodwork which was not fixed at the time of the fire. Mr. MITCHELL decided the first question in the affirmative, and the second negatively. The Sheriff has acted on the architect's conclusions, and has mulcted the plaintiffs in costs.

WE published illustrations a few years ago of the Victorian Parliament House, and it was evident from them that the designer, Mr. KERR, was an architect of great ability. But in Australia, as in Europe, an architect's merit does not receive due recognition. The Buildings Commission in last April recommended that Mr. KERR's salary should be increased from 630*l.* per annum to 1,050*l.*, and that he should have the rights of the first-class professional division of the public service. It will scarcely be credited that the arrangement was not carried out in its entirety. It appears that, through some unknown reason, a less generous remuneration will have to be accepted. By a recent resolution, it is proposed to enter an amount of 5,000*l.* on the estimates in order to provide an annuity for Mr. KERR. It is at the same time recorded that Mr. KERR has devoted a long time to his great building, and received small remuneration. The case is to be regretted; but at the same time we hope it will serve as a warning to official architects. If they pursue the even tenor of their way, they are likely to be happier than if they give way to ambition and seek extra commissions. Experience shows that public bodies are not to be trusted unless a bargain is made before an architectural work is commenced, and they have always little compunction in leaving one of their servants in the lurch. Mr. KERR has been unjustly treated, but he should have suspected dealings by which he was rewarded with 500*l.* or 600*l.* a year.

THE new statue of the Duke of WELLINGTON opposite Apsley House, which was unveiled a week ago, does not dwarf the surroundings by its excessive size. It is evident that a truer notion of the value of scale is spreading among sculptors. Another good feature is the mosaic platform, which imparts colour, and is a good specimen of Messrs. BURKE & Co.'s handiwork. There is no chance of variation in representing the great Duke, for he must appear as he did at Waterloo. The introduction of figures of English, Irish, Scotch, and Welsh soldiers at the angles of the pedestal is an innovation, for the stereotyped design used to suggest that the Duke defeated the French army by pointing his telescope at them. The figures in Piccadilly are fair examples of Mr. BOEHM's skill, but it would be too much to expect that he could take more interest in them than if they were mythological beings. For a national monument at least an Englishman should be selected.

## THE ARCHITECTS OF WESTERN AMERICA.

IT is exactly four years since we noticed the proceedings of the first convention of the Western Association of Architects, which was held at Chicago. Knowing how few were the practical results from the congresses of architects in this country, we were compelled to admire the more definite aims of their American brethren. The Chicago architects, we wrote, "see no necessity for separating architecture from architects, and the first place in the programme is given to subjects which are essential to the existence of the profession." The successive meetings or conventions have been no less consistent, and every year something is done towards the improvement of the profession of architecture by inducing the members to cultivate *esprit de corps*, and compelling the public to recognise that an architect is the equal of the surgeon or the lawyer.

The fifth convention, of which a report appears in a special number of the *Inland Architect*, was held in Chicago last month, under the presidency of an Englishman, Mr. SIDNEY SMITH, of Omaha. In his address, Mr. SMITH, while admitting the good work which has been accomplished in overcoming prejudice both within and without the profession, pointed out how much remained to be undertaken. It was, he said, of the utmost importance that all the architectural societies of the States should form one consolidation or confederation, which should be under one direction and governed by one code of ethics. In the ranks every reputable practitioner of architecture in the United States who can comply with the code of ethics so established should be enlisted. The confederation should be possessed of a fund sufficient to support a bureau of professional information and legal advice for its members. In a young society like that of America there is less difficulty in confederating than in this country, and there may also be an advantage for Americans in the process, although it may not be plain to us. But the foundation of a bureau of information (assuming, of course, that the words can be taken literally) does not sound well, although it may serve as a bait for architects, if there are any in the Western States, who are rather wanting in the knowledge which should be possessed by every man who practises as an architect. If technical information can be imparted on application to the bureau, what is the use of a long course of training or an investment in books of reference? Once open a depository of knowledge, and it will be difficult to draw the line between applications for ordinary and extraordinary information and to define the things architectural which should be generally known. Then, again, in a country like America how is secrecy to be maintained in the business of the bureau? A Western VITRUVIUS may startle his township with the extent of his knowledge about some historical or practical matter, and in consequence obtain the honour of a report with sundry lines of tall capitals for heading. But suppose it leaks out that he derived his facts direct from the bureau, there is no knowing what might befall the orator. The American architects wish to be as much esteemed as members of other professions; but, if so, it is hardly wise to seek after an institution which neither attorneys nor doctors would care to imitate for themselves. With keen-eyed people like the Americans we doubt if anything could be more dangerous than to suggest that professional knowledge is readily and cheaply obtainable, and the proposition for the setting up of a bureau we consider as the weak point of Mr. SMITH's address.

As well as we can discover, there was nothing done during the meeting to carry out the President's idea. Already a committee for collecting legal decisions in building cases exists in connection with the Western Association, and no objection can be raised to the work of the members if kept within due limits. Even the best of the American lawyers, it is stated in the committee's report, are poorly posted in building law and are unsafe advisers. We get a glimpse of American courts in the lamentation over lost time, which the report expresses in this fashion:—"How many good and serviceable hours have all of us spent in court-rooms while a couple of lawyers who knew little, a judge who knew less, and a jury that knew nothing about the relative claims of the contestants, or the many complications connected with the erection of a building, were

endeavouring to settle some trivial misunderstanding, which the architect, if backed by proper precedents, could have adjusted to better advantage alone." We have spoken above of limits, and it may appear an ungracious suggestion, but the report admits that "the indefiniteness of the committee members' ideas on the subject was the greatest obstacle in getting serviceable work from them"! The first work necessary was, therefore, to instruct the committee, and a volume was prepared "somehow for that purpose, which an enthusiastic committee-woman, Mrs. LOUISE BETHUNE, declares to be "a hand-point and clear model for future work."

One of the dreams of the committee is to get hold of that prodigy which is as rare as the phoenix—a lawyer who is willing to work without any thought [of fees, and finds sufficient remuneration in the honour which he received by being consulted by the architects. As yet he has not turned up; but that the wonderful lawyer exists, and will some day come and solicit employment and carry on cases "contented with the honour for his emoluments," as one member expressed it, are among the beliefs of the Western architects.

The question of licensing architects was one of the first debated at the convention. A committee has charge of it, but as yet the various legislatures are indifferent to its advantages. One architect who tried to operate on the American makers of laws said how "they looked upon the asked-for legislation as they do on some other trades union measure—something to enable architects to earn a little more money—and they paid no attention to us." Another architect related that he had had considerable talk with most of the influential members of the Ohio Legislature regarding the Licensing Bill, but they said some years must elapse before it could be passed, as the public would be very much opposed to a bill which would compel a man to go to an architect for plans and specifications whenever he wanted to build. The chairman said that from his experience the only difficulty in the way of rushing the bill through the Legislature was want of money. According to a fourth speaker, the legislators considered the Bill to be a scheme by which architects sought to cut out the country carpenters from constructing such small buildings as they are in the habit of constructing, and thus to deprive them of rights. Mr. CLAY, who was one of the pilots of the obnoxious Bill, explained how they proposed to get over the carpenter difficulty by agreeing that builders should be privileged, but that other people who practised architecture as a business should take out licenses. He admitted that every one had as much right to be his own architect as to be his own physician or his own lawyer, but when a man who took employment from another as an architect, or described himself as "practising architect," he should show some guarantee of the proficiency like the druggist, physician, dentist, and attorney. But the value of a guarantee which depends on an examination was suggested by Mr. ADLER afterwards when he said there was nothing in the Bill to prevent the tailor or the shoemaker from practising architecture provided the examination of the State Board is gone through. Can any one suppose that in America or in England the examination would be sufficiently comprehensive to be a fair test of ability, or would go beyond what is required for the humblest sort of technical employment under the State? In England it is well known that the demand for the registration of architects is advocated by no more than a few people, and the little interest taken in the subject in America is evident from the acknowledgment of Mr. CARLIN (who was afterwards elected president) that he had not seen a copy of the Bill. When a leading architect does not trouble himself about the proposals, the legislators are acting rightly if they turn a deaf ear to the diplomatists who wish to make use of them for the passing of a measure when there is not unanimity among architects upon its merits.

Many will say that, with a system of registration after examination, there would be clearer ideas upon questions of professional ethics, and a more agreeable recognition of one's rights. The committee of forty-eight members that had been appointed by the Western Association to prepare a code of ethics seem to believe in the advantage of doing nothing. "I have allowed things to take their natural course," says Mr. SULLIVAN, the chairman, "and have heard

nothing from the sub-committees, and the sub-committees have also allowed things to take their natural course, and have heard but little from me." Yet he considers, and justly, that a code is needed which should define the relations between architects and between clients and architects. It should state, says Mr. SULLIVAN, when one architect is having business relations with a client, that that shall be a sufficient warning that interference on the part of another architect is non-professional and not allowable. It will be admitted that the utility of the regulation need not be confined to America, for something of the kind is required in this country. A report on ethics may be expected for the next convention, since a committee consisting of Mr. SULLIVAN is to prepare it.

A case which illustrates the elasticity of what passes for ethics at present was brought before the convention in a letter from Messrs. SMITHMEYER & PETZ, architects, of Washington. Fourteen years ago their design was accepted after a competition for the Congressional Library of that city. But the perpetual changes of committees, which appear to be an institution in America, involved corresponding transformations of the plans before an order to build was given. An extract from their statement will suggest the trials of the architects:—

For a period of thirteen years, from one Congress to another, we would modify, change, curtail, enlarge, &c., &c., to conform to the ideas of the "powers that were." In this endeavour no less than twelve different designs of the exterior were prepared in various styles of architecture, in Gothic, Romanesque, French, Italian, German, Renaissance, &c. Vast numbers of plans, sections, and studies were made and submitted to try and satisfy the various tastes of the members of the committees, until finally the Congress of 1886 adopted the plan in the Italian Renaissance style, naming our plan specifically in the Act. For all these plans, for our services as expert architects requested by these Congressional committees, extending through a period of thirteen years, and for the heavy and onerous expenses to which we have consequently been subjected (including a trip to Europe by the senior partner, for which only travelling expenses were allowed), no compensation has been paid or allowed.

The works were hardly started before the architects found they were superseded. The reasons for this step, they say, are well known to the profession in America. It was, they assert, because they declined to accept work and materials which did not correspond with the requirements of the specification. In such a case influence is everything in Washington lobbies, and as Messrs. SMITHMEYER & PETZ are less powerful in that way than their opponents, the commission for the building, which was to cost four million dollars, was taken from them. The amount of compensation is left to the settlement of the Secretary of the Interior, who will naturally object to saddle the administration to which he belongs with an outlay which former ministers incurred. Cases of the kind are not, however, uncommon in America, and for that reason probably the convention made no fuss over the Library scandal. One member quoted the opinion of a congressman to the effect that it was only a result of the competition system. Afterwards the letter of Messrs. SMITHMEYER & PETZ was referred to a committee having charge of another subject.

The subject which engrossed most attention was consolidation, or, in other words, the proposed amalgamation with the American Institute of Architects. In America, as in England, there is an active centralising spirit at work, and the aim of it is to break down independence in all forms. The Western Association is a young and go-ahead Society, the American Institute is the oldest Society of the kind in America, and as age counts for much, it can set up claims for many qualities which few would care to question. It was therefore proposed, and the general interests of the profession were put forward as the main inspiration of the proposal, that the two societies should become one. But the American Institute, while willing to admit the members of the Western Association into its ranks, insists on certain conditions. In the former there are grades, whilst in the West the principle of equality is acted upon. The Institute wants to place three hundred members of the Association in the grade of Associates, and will allow the full rights of membership to only half that number, or, in other words, to one-third of the Western Association. Can any equivalent be obtained by the architects, who are thus declared to be of inferior quality, although it is not clear what kind of test was applied to assess their merit? Nothing appears in the reports to settle the question, and if many members will

not decline to allow themselves to be classified as associates according to the whims of a few office-bearers, it will be a sign that the lamp of sacrifice in regard to private interests burns brightly in the West.

It is difficult for a stranger to understand both sides of the question of consolidation, but apparently the Western Association is risking everything that is characteristic by the leap in the dark which it is about to undertake. For the reflected respectability which is supposed to come from the union with the older Society, it will have to sacrifice the liberty which has already produced so much good. We know of no Society with so short an existence that can produce a more creditable record than the Western Association, and yet the future is to be jeopardised; perhaps it would be nearer the truth to say that the Association is not to have a future, because there are some men who believe in a mammoth Society in which the members will be compelled from their numbers to leave the government to a few.

At every convention of American architects the defects of the Government officials are sure to be proclaimed. The last one at Chicago was not an exception. The committee who have charge of the efforts towards obtaining a reform have to admit "that there was no sympathy with the movement in the Committee on Public Buildings and Grounds of the House of Representatives." The legislators considered the Government buildings at Washington and the Government buildings about the country to be the *ne plus ultra* of architectural achievement. With so much infatuation in Congress it was vain to urge that any amendment of the process for producing public buildings was necessary. The committee, strange to say, do not propose any attack on the Government system by the consolidated societies. They recommend that every member "should constitute a committee of one, charged with the duty of calling forth from individual citizens, and from the press, expressions of opinion upon a system under which the Government of the United States cannot employ in its professional service architects of as high standing and as great professional and business ability as those employed by wealthy corporations, or even by the average private citizen." If in a case of this kind consolidated effort is futile, what reason is there to expect that it will conquer in architectural affairs in which the public or the Government will be on one side? If individuals can succeed in bringing about a reform of the architectural department of the Government, they might be trusted to look after their own affairs. If they should fail, they cannot anticipate much aid from the magnified American Institute.

With the aid of the Western builders, a form of contract has been prepared by a committee of the Association, and will in time be accepted by architects and builders. In order to avoid any chance of introducing modifications which might affect the tenor of the clauses, the form is copyrighted, and will therefore have to be used as prepared or not at all. But practical work of that kind is not likely to be repeated under the new conditions, which will be prohibitory of experiments that are not initiated in New York.

The only subject of an extraneous kind that was considered related to the introduction of the metrical system. From an inquiry made among the civil engineers of Boston it would appear that they are in favour of an abandonment of the units at present employed. Mr. ADLER, who is a prominent member of the Western Association, found that the metric system is now considered as a blessing in most parts of Germany. In America there is a diversity of opinion upon the subject, but as a conference of the American Customs Union will be held next year to consider uniformity of weights and measures, it is considered that the metric system may gain the day.

This convention will, we suppose, be the last of the Western Association of Architects, and henceforth it will neither have local habitation nor name. As a branch of the American Institute it may hold meetings at which papers will be read, but the proceedings will have lost the interest of past years. The Western architects will have to go far from Chicago for guidance, and must submit themselves to leading strings. If any compensation will be forthcoming for the loss of independence, the change may be condoned, but at present there is no prospect of the Western architects finding more respect from their clients or less rivalry among themselves.

## THE SOCIETY OF FRENCH ARTISTS.

ON the 27th of this month, says the Paris correspondent of the *Times* when writing last Friday, the Society of French Artists will hold its annual meeting, and there is every prospect of a severe conflict. This society consists of all persons whose paintings, &c., have been exhibited at the Paris Salon. There are now upwards of 2,400 members, and they elect a managing committee of ninety fellow members. The Society has existed eight years independent of State control. The committee of ninety has appointed a sub-committee of twenty-six, nine forming a quorum, and the members of the sub-committee are practically masters of the situation. It is urged that the committee has behaved in an autocratic manner by imposing rules without consulting the Society, bringing members together only once in the year, and allowing no proposals to be made unless they are sent in at least a week in advance, and bear the signatures of 100 members. Of course it requires much time and patience to go the round of so many studios. Nevertheless, this has been done in the present instance, and a proposal bearing 115 signatures will be presented, demanding such alterations in the rules of the Society as will insure a constant change in the members of the jury who are to judge what works of art shall be exposed in the Salon. Many of the best-known artists have signed this requisition, notably MM. Carolus Duran, Dalou, Detaille, Cazin, Gérôme, Regamey, Roll, and Meissonier.

In order to carry out the project it will be suggested that a committee of 120 artists shall be elected freely by the whole Society. Half this committee will constitute the jury, and they will be appointed by the drawing of lots. Thus, even if the same persons were constantly re-elected on the committee of 120, the acting jury would be varied by the hazard of the lottery. Further, it is proposed to divide the work and the jury into five equal sections, so that each jurymen should have less to do, and be able to perform his task more conscientiously. By submitting at present all the pictures to one single jury the strain becomes too great, and the eyesight and judgment of the jurymen are seriously impaired, at least for the time being. Moreover, the jurymen, being to some extent independent of the control of the Society which they represent, are open to accusations of partiality. It is said, for instance, that preference is shown to pupils from the schools of teachers on the committee, and that these teachers insure their own re-election by admitting as members of the Society so many of their own pupils. This places the artists who do not attend any school at a great disadvantage.

Whether these assertions are justified or not, there is a strong feeling in favour of modifying the regulations so as to prevent any monopoly in the management of the Paris Salon, and to promote the interests of French art.

## KIRKSTALL ABBEY.

WE have pleasure in stating, says the *Leeds Mercury*, that, through the munificence of Colonel North, Kirkstall Abbey will now become the property of the town of Leeds. By his very liberal gift to the Infirmary, the Yorkshire College, and in other ways, Colonel North has shown the great interest which he feels in his native town, and it will afford much gratification to the inhabitants of the borough to learn of this, his latest act of generosity. It may be recollected that at a recent meeting of the Town Council a resolution was adopted authorising the purchase of the abbey for the sum of 6,000*l.*, and at the recent sale of the Cardigan estates in Leeds the Town Clerk (Sir George Morrison) offered 6,000*l.* for the abbey and grounds, but it was refused, the reserve price being 10,000*l.* On Friday week—the concluding day of the sale—it became known that negotiations had been entered into for the purchase of the abbey and grounds, and also the Abbey House, by gentlemen who intended to utilise the two estates as a place of public amusement. This having come to the knowledge of Councillor Edmund Wilson, he at once offered the reserve price for the property, namely, 10,000*l.* for the abbey and grounds, and 3,500*l.* for the Abbey House. On Tuesday, when the contract was completed, Mr. Wilson sent a letter to the Mayor offering the abbey estate to the Corporation for the sum of 10,000*l.* The Mayor had an interview with Alderman Sir Edwin Gaunt, who, with the concurrence of his worship, gave notice that he would move at the next Council meeting that the Corporation purchase Kirkstall Abbey and grounds for the sum of 10,000*l.* In the meantime, Colonel North became acquainted with the position of affairs through Mr. Charles England and Mr. A. D. Holmes. These gentlemen, on behalf of the Leeds Mechanics' Institution and Literary Society, had an interview with Colonel North at the Hôtel Métropole in London, their object being to solicit his assistance towards the expenses incurred in the erection of a new building for the Boys' Modern Day School. A gift of 250*l.* was promised, and it was

arranged that Colonel North should be present at the opening ceremony on January 15. Mr. England and Mr. Holmes then mentioned the question of the sale of Kirkstall Abbey, and a fear was expressed that the estate might not be secured for Leeds. Colonel North said, "I will, if I can, purchase the abbey and present it to the town." Negotiations were immediately entered into with Mr. Wilson, who was informed that Colonel North wished to take the contract off his hands for the purpose of presenting the abbey to the town. Mr. Wilson agreed to the suggestion, and on the 21st the Mayor received from Colonel North the gratifying intimation that he intended to purchase Kirkstall Abbey and grounds from Mr. Wilson, and to make a free gift of them to the borough of Leeds. In reply, the Mayor sent the following telegram to Colonel North:—

"Have just received the gratifying intimation that you have generously offered to present Kirkstall Abbey to the borough of Leeds. Please accept my warmest thanks on behalf of the inhabitants of the borough of Leeds."

## THE NEW PARIS LABOUR EXCHANGE.

THE most practical result achieved by the labour organisations of Paris, says a correspondent of the *Times*, is undoubtedly the creation of the Labour Exchange. This will be so vast and remarkable an establishment that it will not fail to attract the attention of all who study French public institutions. Workmen are at present busy laying the foundations, on a site formerly occupied by a panorama at the corner of the Rue de Bondy and the Place de la République. The position, it will be seen, is very central, and the land was consequently expensive. It has been purchased by the Municipality for 40,000*l.*; but the expenses are further increased by the fact that the soil is very unsuitable for building purposes. A small stream, or water-course, formerly passed over this spot, and it is necessary to dig 30 feet below the level of the street and 5 to 6 feet below the water-level to reach a solid foundation. The building will rest on 90 piles, sunk through the earth and made of Portland cement. These are now nearly finished. As the foundations are the most difficult part of the undertaking, the architect hopes that the outer walls will be completed in time for the great Exhibition of next year.

On the basement of the Exchange will be the stoves, the ventilators, and the electric apparatus. Then there will be vast bare rooms with no other furniture than wooden benches. Here those labourers, porters, and workmen who at present are in the habit of standing at the corners of certain streets or open spaces waiting for employment will be allowed to congregate. They will at least be under shelter; while, on the other hand, employers will know exactly where to find the men they need. In this basement also provision is made for two offices for the registration of any demands for work and similar purposes. To prevent confusion, the basement is divided into three waiting-rooms of different sizes and is accessible by three flights of stairs. Above, at the main entrance, on either side of a large vestibule, will be found a porter's lodge, an office for general information, and a post, telegraph, and telephone office. The central yard beyond, roofed over, will become the large meeting-hall of the Labour Exchange. Efforts will be made to get this portion completed in time for the International Workmen's Congress to be held in Paris next year, probably in the month of August. The central hall will measure 24 by 22 mètres, and will therefore hold about 1,500 persons. But at the further end there will be a platform or stage measuring six by ten mètres and capable of holding some 150 more persons. This will prove very convenient when a society receives other societies, or for separating delegates from the general public. Further, there will be three smaller halls, divided only by partitions from the large hall, which might serve as lobbies in the event of a congress, or as places where smaller meetings could take place. These smaller halls will hold about 200 persons each. If, however, the partitions are removed and these smaller halls joined to the central hall, a meeting of more than 2,000 persons could easily be accommodated.

The first floor is destined principally for administrative purposes. The administration, or general managing committee, which is freely elected by the trade unions of Paris, will have a large committee-room with a special entrance and vestibule. Then there will be a room for the general secretary and six separate rooms for clerks. The Service of Statistics is to possess the same accommodation, namely, a committee-room, a general secretary's-room, and six clerks' offices. Here all general labour statistics are to be compiled and held in readiness for all practical purposes. Six more rooms are allotted to what are termed work inspectors. Some time ago a proposal was made for the appointment of five workmen inspectors, who were to visit all the places where work was done for the town, and see that the conditions of the contracts were faithfully executed, that the sweating system was not introduced, that the rate of wages, according to the series, or tariff, established by the town, was

duly paid, that proper precautions were taken to prevent accidents, and that the laws for the preservation of public health were strictly observed. The trade unions were to prepare a list of fellow trade unionists whom they desired to see appointed as inspectors, and the Municipality would select five out of this list for the purpose. The inspectors thus appointed were to be paid by the Municipality a salary of 12*l.* per month. This proposal was accepted by the Paris Municipality, but the Government refused to sanction the measure. Nevertheless, offices are to be built for these inspectors, the question will be revived, and it is anticipated that ultimately the Government will give its assent.

On the first floor there will also be a library, a reading-room, and a room for technical lectures. The second, third, fourth and fifth storeys are all to be built on the same plan. Each will possess a committee-room and 29 small and six rather larger offices. In these offices will be the secretary of a trade union, and perhaps one other official. When the society wishes to hold a committee meeting it can occupy one of the many committee-rooms vacant. If the whole trade desires to meet then one of the large halls will be at its disposal. The small offices measure about 10 feet by 13 feet, large enough for a secretary and one or two visitors. Thus on the upper floors of the building no fewer than 140 trade unions can be accommodated with separate offices. This is precisely the number of trade unions that now have their headquarters at the temporary premises in the Rue Jean Jacques Rousseau, where there are only 20 offices and two meeting halls. But all the societies will not go from the temporary to the new premises. It is proposed to keep the former as an *annexe* to the Central Labour Exchange. As it is very near to the Halle Centrale, all trades connected with the food supply of Paris might continue to have their offices in the Rue Jean Jacques Rousseau; and also the societies connected with commerce, such as associations of clerks, shop assistants, &c. At present the Paris Municipality, besides providing the temporary premises, gas, fire, and three attendants to clean, &c., allows the managing committee 800*l.* per annum for working expenses. This subsidy will have to be very largely increased when the trades remove to the new and vast Labour Exchange on the Place de la République.

According to the estimate, this building will cost, furniture included, 1,920,000*fr.*, and, together with the price of the land, make, in round figures, 3,000,000*fr.*, or 120,000*l.* M. Bouvard is the architect, and has selected for his façade a design at once serious and solid. There will be ten handsome pilasters with Corinthian capitals. Blocks of white stone will be employed. From three separate sides wide staircases give easy access. There will be both gas and electric light, and mechanical apparatus to insure ventilation. Altogether the plan is carefully prepared, and it may be said, without hesitation, that in no country has so elaborate a provision been made for the exclusive benefit of working-class organisation.

#### GLASGOW ARCHÆOLOGICAL SOCIETY.

A MEETING of the Archæological Society was held on the 20th inst., Mr. John Honeyman, architect, in the chair. Mr. Dalrymple Duncan, F.S.A.Scot., hon. secretary, stated that considerable alarm had been recently caused by certain proposed operations of the North British Railway Company in connection with the projected construction of a branch line from near Bonnybridge to Camelon Chemical Works. These operations, it was feared, threatened eventually to sweep away part of one of the best-preserved portions of the Antonine Wall still remaining, for while the proposed branch railway itself runs on the north side of the vallum, the line of deviation is so drawn as to include that specially interesting section at Tayavalla which was examined with so much pleasure by the members of the British Archæological Association in September last, it being thus evident that if the railway company extend their operations at this point on the south side of the wall, every vestige of this section of the rampart will be destroyed. The matter had been brought under the notice of Mr. Forbes of Callendar, who had communicated with the railway company, urging that if possible all injury to the wall should be avoided. It was agreed that a committee should be appointed for the purpose of representing to the North British Railway Company the importance of preserving from destruction so interesting a relic of the Roman occupation of Briton, and the extreme desirability of taking all possible measures to keep the line of deviation on the north side of the wall. The President afterwards exhibited an urn which was found by workmen digging a foundation at the head of the hill between the Rottenrow and George Street, a little west of the High Street. It was entirely dissimilar from any other urns he had seen, and he believed it to be of the Romano-British period, or even somewhat later. He also exhibited a stone hammer which was found at Greenhaugh, Huntly, and which, from its shape and finish, he inferred had been used as a weapon of war. Mr. T. Stout exhibited a

piece of wood found in Iceland, shaped like a spear-head, and which, for the purpose of hardening it, had apparently been impregnated with mineral water. He commented on the fact that although wooden weapons in plenty were found in the South Seas, this was the first indication that they might have been used by Scandinavians. Mr. A. C. Macintyre, F.S.A.Scot., afterwards read a paper on a ruined chapel at Dunswood, near Castle Cary; and Mr. Hugh C. Hamilton, a paper on the "Badges of the Highland Clans." Mr. Hamilton showed that floral badges were of very considerable antiquity, and remarked that it was pleasant to know that the two oldest badges of Scottish royalty were still displayed on the collar of the Order of the Thistle, which was formed of sixteen thistles alternating with as many bunches of rue sprigs. Mr. Macintyre and Mr. Hamilton received the thanks of the Society for their papers.

#### THE LATE RICHARD REDGRAVE, R.A.

THE Treasury Minute of August, 1875, by which a special retired allowance was awarded to Mr. Redgrave, gave the following statement of the services which he had rendered to the country:—

"The Lords of the Committee of Council on Education inform the Board (Treasury) that they transmit Mr. Redgrave's application for a pension with very great regret, but having once induced him to postpone his retirement, they feel that at his advanced age (71) they cannot properly urge him again to postpone his application for relief from the heavy labours which he has for many years discharged, with so much credit to himself and with such signal advantage to the State. They further inform the Board that to recount the services which Mr. Redgrave has rendered in the various offices which he has held would be to write the history of the Art Department under the various names it has borne from the date of its first establishment. They state that the present flourishing condition of the art division and the position which it holds, not only in this country but in the public opinion of the Continent, are the best testimony which can be given to the value of Mr. Redgrave's labours in founding and directing the existing system of art instruction throughout the United Kingdom, and in establishing and developing the art branches of the South Kensington Museum."

Colonel Donnelly relates another circumstance which does credit to the artist. Mr. Redgrave was pressed by Mr. Sheepshanks to accept the custodianship of his well-known collection of pictures, with a salary and residence in Rutland Gate; but with characteristic unselfishness he urged the step which Mr. Sheepshanks ultimately took, of presenting the whole collection to the South Kensington Museum.

#### A PROFESSIONAL MENU.

ACCORDING to Mr. Bryce, M.P., there is some hope for the Americans, since they are so largely endowed with the gift of humour, which never was more needed than at present. The following copy of the bill of fare which was used at the last dinner of the Arkansas Society of Engineers, Architects and Surveyors, will suggest the enterprise of the humourists in turning the most prosaic things to account:—

##### *Specification of a Banquet.*

*Foundation.*—The foundation shall consist of meats, laid as follows:—Roast turkey, well set in cranberry jelly, with ornamental belt courses of roast venison, broiled ham, and pickled ox tongue. The interstices to be well filled with chicken, shrimp, and potato salad.

*Water Table.*—Shall be of selected, well-dressed celery, English chow-chow, mixed pickles, French olives, Worcester-shire sauce and cold slaw.

*Superstructure.*—The superstructure to be of those ancient and substantial materials known as milk, rye, and light bread.

*Ornamentation.*—Ornamentation to consist of pyramids of meringue, pyramids of fruits, pyramids of wine jelly, ornamented angel food, and ornamented sunshine.

*Inside Finish.*—Inside finish to consist of pound cake, jelly tarts, egg kisses, almond and cocoanut macaroons, lady fingers, and almond spongelets.

*Plastering.*—Centre pieces to consist of oranges, bananas, apples, London layer raisins and Malaga grapes, to be well secured to ceilings and thoroughly fastened with Neapolitan ice cream, pine-apple sherbet, fruit and home-made candies, crackers and cheese.

*Hardware* will consist of the best-selected mixed nuts, each opening to be provided with a full set of nut picks.

*Painting.*—The whole to receive two flowing coats of French coffee, and as much water as may be necessary to make a good job.

*General.*—The whole to be under the immediate charge and supervision of Fred Rossner, architect to the Society.

**TESSERÆ.****The Turnerian Periods.**

J. RUSKIN.

THE works of Turner are broadly referable to four periods, during each of which the painter wrought with a different aim or with different powers. In the first period, 1800-1820, he laboured as a student, imitating successively the works of the various masters who excelled in the qualities he desired to attain himself. In his second period, 1820-1835, he worked on the principles which during his studentship he had discovered; imitating no one, but frequently endeavouring to do what the then accepted theories of art required of all artists—namely, to produce beautiful compositions or ideals, instead of transcripts of natural fact. In his third period, 1835-1845, his own strong instincts conquered the theories of art altogether. He thought little of "ideals," but reproduced, as far as he could, the simple impressions he received from Nature, associating them with his own deepest feelings. In 1845 his health gave way, and his mind and sight partially failed. The pictures painted in the last five years of his life are of wholly inferior value. He died in 1851.

**Encaustic Painting.**

S. FISHER.

The surface, whether of plaster or stone, to be painted on is heated by means of a portable charcoal fire till one can scarcely bear the hand upon it. A greater heat will not have the effect of causing the solution to penetrate any further than a moderate one; about one-sixteenth of an inch is the utmost depth to which a common red tile will absorb it, when made nearly red-hot. It is then to be thoroughly saturated with a mixture of about two parts of white wax and one of gum damar, dissolved in turpentine, which is the medium to be used throughout the work. The addition of gum to the wax is necessary, as, alone, the wax would be too soft to work upon pleasantly, but any increase in this quantity of gum has a tendency to crack when the colours are laid on in any body. The employment of gum copal, or elemi, as being harder gums than damar, is preferred by some. Mr. Gambier Parry's medium is of this kind; but as he omits altogether from his formula the agency of heat, either to combine the finished work with the under-coats, or for the preparation of the wax, and also lessens the quantity of wax, his is not an encaustic process. These harder resins are more difficult to deal with, they require a stronger solvent than turpentine, or that a little oil should be added to the composition, which it is most important—on account of its tendency to darken—to do without; when used they are no more impervious to damp than damar, and that they should be less soluble in turpentine simply is a very doubtful advantage. When the wall is sufficiently cold, the ground colour may be laid on in the usual way; but, if more than one coat is necessary, it is essential that the first is left sufficiently long to become hard before putting on the next. The only difficulty of manipulation attendant on encaustic painting is the tendency of the upper coats to penetrate those beneath, but a little dexterity in handling will obviate this. Upon this ground the subject is to be painted, with colours ground in the same preparation of wax and resin, and thinned to an agreeable consistency with turpentine. The work may be added to or altered with all the facility of oil colours, and, when the whole is completed, it is to be reheated regularly and slowly by means of the brazier. It is sometimes the practice, before this final heating, to varnish the whole surface with the wax medium; but if the wall, before commencing, has been thoroughly saturated, and a sufficiency of it has been used with the colours in working, this will not be found necessary. The result of this burning in is, that the finished painting, the ground, and the preparation of the wall, are all melted and amalgamated together in one homogeneous substance, united to the wall in the most perfect manner, and remaining brilliant and imperishable.

**Gothic Buttresses.**

S. HUGGINS.

Of all the features of a Gothic pile, the one that most loudly calls for the refining influence of the Classical style is the buttress. In the great Mediæval examples of this feature it is considered a merit that it is of the form best calculated for successfully resisting the lateral thrust of the groined vaults; that it is formed and disposed in strict and literal obedience to the law of the resolution of forces, and, therefore, without waste of its materials, every particle of which is actively employed to the exclusion of any useless or expletive masonry from its composition. Now, it appears to me that it is only in the comparatively prosaic works of the engineer, and not in every work of even that class of production, that strict economy of materials should be enjoined, and that a buttress or anything else fashioned with an eye to a material use only and to the embodying of proof of dynamical and statical

knowledge and skill, does not belong to architecture, which, as an art of the beautiful, requires a greater sacrifice to the sense of beauty than is involved in the mere carved adornment of the form arrived at by algebraic calculation. I cannot but think the form itself should be modified by careful considerations with regard to beauty, a ray of which, says Emerson, outweighs all the utilities in the world, and be made as beautiful as would consist with its fully and clearly expressing its office and purpose as a buttress. While the law of forces should be kept fully and clearly in view, such addition of material beyond what stability required should, I conceive, be made as would enable the architect to mould it into the greatest symmetry and grace of which it was susceptible, and enable him, in carrying it up from the ground, to avoid those irregularities which so frequently disfigure it, such as the one-sided set-offs, which are far less pleasing than the slope, which is carried equally round the three sides, and less susceptible of effective and satisfactory decoration. The Mediæval architects did generally go so far as to give the buttress less projection than the outward thrust of the vault required, and supplied the deficiency of lateral resistance by the perpendicular pressure of the pinnacle. This was done less for appearance, perhaps, than to prevent an inconvenient projection of the buttress; but might not a further liberty be taken with it to make it more symmetrical and graceful, and consequently more a feature of fine art? Might we not further reduce the necessity for projection by giving it greater thickness or width, or by giving additional thickness to the wall. But there are examples to show that the buttress can be sufficiently lightened as it ascends, and with entire geometrical regularity, with but little sacrifice of material. There are, I doubt not, various ways of doing it; among the rest, that of turning the upper stage diagonally, which gives it a piquant and pleasing effect. But whether much or little expletive matter be required for the purpose in question, as beauty is indispensable in architecture, we should be quite justified in giving it so much as is allowed in oratory for the sake of sound, and to satisfy the sense of hearing, in adding synonymous and unnecessary words to complete the roundness of a period.

**Gothic Pinnacles.**

A. W. PUGIN.

I have little doubt that pinnacles are considered by the majority of persons as mere ornamental excrescences, introduced solely for picturesque effect. The very reverse of this is the case, and I shall be able to show you that their introduction is warranted by the soundest principles of construction and design. They should be regarded as answering a double intention, both mystical and natural. Their mystical intention is, like other vertical lines and terminations in Christian architecture, to represent an emblem of the Resurrection. Their natural intention is that of an upper weathering to throw off rain. This most useful covering for this purpose is of the spiral form: only let such a form be decorated with a finial and crockets, and we have at once a perfect pinnacle. Now the square piers, of which these floriated tops form the terminations, are all erected to answer a useful purpose when they arise from the tops of wall-buttresses.

**The Lighting of Temples.**

E. M. BARRY.

The question of lighting temples is one of great interest and on which there has been much diversity of opinion. Some have thought that the external light was admitted, and that artificial lights were used for greater solemnity only, as we see at the present day in shrines of great reputed sanctity in the East and in some Roman Catholic churches. Others have suggested that there was a large opening in the centre of the roof admitting light and air as by a skylight. It is easy, however, to see that such a plan would render it difficult to avoid external disfigurement, while it would also fail to protect the interior from rain and snow. Mr. Fergusson has propounded a third theory, namely, that of a clerestory, with openings in the roof to allow light to pass through it. The Egyptian custom is in favour of this suggestion, for in many of their temples—as, for example, at Karnak—such a plan of lighting is adopted, and with a very striking effect. That the Greeks were acquainted with Egyptian work there can be no doubt, and as they transferred the rights of Isis to their own soil, there is no great difficulty in supposing that they may have also borrowed some architectural ideas from the banks of the Nile. It may, perhaps, be objected to the plan proposed that it is not quite consistent with the simplicity of the form of the roof, which would not readily suggest any complication of internal arrangements. There would also be some difficulty with gutters to carry off the water, and no evidence has as yet been discovered to show how this was effected. The temples of the Romans were used sometimes as places of assembly, and there is, therefore, in their case a strong presumption in favour of their having been arranged to receive direct light and air; but I do not think this applies at all with equal force to Greek work. If we consider the small dimen-

sions of the cellæ of Greek temples, there is no great difficulty, as it seems to me, in supposing that they depended chiefly on artificial modes of lighting. They were shrines for the safe custody of sacred statues of the gods, not places in which crowds could assemble, and any openings of the roof would have affected injuriously their protective qualities. The doors being thrown open would also admit a greater amount of light and air in a climate like that of Greece than we can readily imagine in our land of fogs. The simplicity of Greek principles of design must also be insisted on as a difficulty in the way of any suggestion that they employed elaborate contrivances. If they required light in their temples the obvious course would have been to place windows in their walls, and this is precisely what was done at the Erechtheum and also at Agriguntum. May it not well be the case that custom varied, and that some temples were constructed without that external provision for light and air which was thought necessary for others? At the Erechtheum the latter was doubtless the case, and the architect placed windows in the walls. May we not conclude that if they had been needed at the Parthenon they would have been supplied in a similar manner? The chief beauty of the Parthenon was the exterior, and it would scarcely be possible to arrange any openings in the roof which would not be more or less of a blot on its fair proportions.

#### Elizabethan Architecture.

W. H. LEEDS.

That the Elizabethan style possesses historical interest I do not dispute, but that it offers any beauties or advantages to recommend it as a mode of architecture is what I must be allowed most flatly to deny. Its only principle is the disregard of all architectural principles, and of all artistic feeling. Very seldom do we meet with anything in it that can be termed really good, even estimated according to what may be considered the leading taste of the examples themselves; or if there happen to be some particular feature that satisfies the eye, it is a mere solitary bit in the composition—although it is rather an abuse of term so to employ it—without anything to harmonise with it. Besides which, notwithstanding their licentiousness of design, the examples of this style betray great dearth of ideas and poverty of imagination; for, be it observed, there is a most wide difference between whimsies and fancies and fancy itself. I have met with some people who, in aiming at being amusingly lively, have only been impertinently frisky, nor is it a small degree of awkward friskiness that characterises the style in question, and causes it to appear even more dull than it else might. It is no more than right that we should know what it really was; but its examples ought to be held *in terrorem*, certainly not for imitation, except it be that species of imitation which enables an artist to appropriate what is available for better purposes, rejecting all the dross. Yet those who have of late served up this style to us have generally taken care to give us garbage and all. Certainly no one has hitherto attempted to discriminate between its best and worst qualities, or to point out what it offers for adaptation to our present purposes; since, leaving taste entirely out of the question, it has nothing whatever to recommend it as a mode of building adapted to our present habits and tastes, certainly nothing on the score of comfort and convenience, on that of economy perhaps even less, since it is only lavish profusion of decoration that can conceal its native ugliness. I may be told that it is a truly national style, that of our ancestors; national nonsense! So were trunk-hose and cumbersome ruffs at one time our national dress, yet what man—I do not say of sense, but in his senses—would wear them now, unless determined to establish for himself, at all hazards, a character for singularity? We do nothing else like our ancestors; then why, in the name of common sense, should we put ourselves into their most grotesque and unseemly architectural fashions?

#### Subways in Towns.

M. O. TARBOTTON.

The advantage of subways (if safe for gas-pipes) is universally admitted, and their most earnest opponents have failed to show any case against them for water, telegraph, and similar purposes (*vide* Minutes of the Select Committee, June 1864); but in respect of gas-mains there undoubtedly is possible danger (as in every place to which gas is conducted), unless sufficient means of ventilation are provided, and the best modes employed in making and continuing the joints of mains and service-pipes. I entirely believe in the statement of Mr. Hawkesley, that in a well-managed company the escape from the main is very slight indeed (say from 2½ per cent. to 5 per cent.); but I venture to contend that in a well-regulated subway, escape from the mains, to become dangerous, need not take place at all, for the following reasons:—1. That they are not subjected to the perpetual vibration caused by street traffic (in a subway there is no vibration). 2. That they are not constantly disturbed by excavations around and under them for services and drainage operations. 3. That they are under

regular inspection, and the joints can be recaulked when necessary, or bitumenised or varnished from time to time. 4. That oxidation would be less rapid. Furthermore, if an insidious escape of gas happened, an ordinary ventilation would prevent serious consequences. The wrought-iron services are the greatest promoters of leakage; and during a daily experience of underground works for years I have scarcely ever found a perfect service-pipe which was not new, or nearly so. The lime of the pavement concrete and the damp of the soil destroy the pipe, and the traffic loosens the joints. Now, this may be prevented by using lead services; but in a subway the destructive influences mentioned would not operate to anything like the same extent with wrought-iron, and renewal would be readily accomplished. It has been stated that under the present system escaped gas is absorbed by the soil, and that soil forms the best cushion on which to lay the pipes. If this be the opinion of gas companies, the subway plan offers no impediment, as on the side of the subway intended for gas-mains the same may be imbedded to any required extent; in fact, this is already the case in Covent Garden subway. Leakage by endomose action has been advanced, but if gas companies prove all their pipes, as they profess to do, the pressure employed in gas-mains will altogether be insensible. It is true, if a large pipe be accidentally broken, the same damage might arise as if the casualty occurred in a street or any other place; but if large operations were in progress in the subway, corresponding precautions would (and could most easily) be taken to meet the contingency of accident; and it is only reasonable to expect that in a large system of subways the control and management thereof would be in the hands of a single and responsible authority. It is the interest and duty of corporations and other bodies having the charge of the highways and streets of large towns to prevent as much as possible their constant ravishment; and if the subways now proposed will effect this object without detriment to the companies, they ought to be compelled by the Legislature to adopt them.

#### Classic and Gothic Columns.

G. G. SCOTT.

In no feature is the difference between Classic and Gothic architecture so strongly marked as in the column. In the former one general ideal alone prevailed—the round shaft with a capital, and with or without a base. In the latter this normal type is equally admissible and equally honoured, but in addition to it an almost endless list of forms are introduced. In the first place the round column is converted at pleasure into the octagonal or other polygonal form—this is a mere variety of the normal type; then either the round or the polygon is flanked by four smaller shafts, attached or detached, and these subsidiary shafts may be increased in number, subordinated one to another both in size and salience, and may be all attached, all detached, or the attached and detached shafts may be used alternately, or in any other order in the same pillar. Then, again, instead of the cylindrical pillar, we may have four cylinders united in one, and these may in their turn be made the nucleus round which detached or attached shafts may be grouped; or we may have two or more separate cylindrical main shafts carrying the load, and may group subordinate ones round them; and again we may take other forms of nucleus, as the square, the canted square, or a pier with receding orders, and place our shafts round them; and finally we may form groups in which no specific form of nucleus is to be traced, but which consist of shafts arranged with reference to the superincumbent arch alone. The number of changes which may be rung on these varieties of pillar are absolutely endless, though it is not desirable to indulge too much in the more intricate forms of grouping; but, as a general rule, to keep to forms which are naturally suggested by the duties the pillar is designed to perform. When detached subsidiary shafts are used it is somewhat unnatural to joint them in their length without introducing some visible means of tying them to the main pillar within. This necessity gave rise to the use of the moulded band, which forms so beautiful a feature in the pillars of this period. It is sometimes made of brass, but more usually in stone or marble. The bases of columns throughout the Romanesque period were most usually founded on some traditional variety of the attic base. The resemblance is often obscure, but in many cases very close. Towards the end of the Romanesque period very great attention began to be paid to the sections of base mouldings, and in Transitional works they are often more beautiful than at any other period. The difference between these bases and the ordinary Attic base is of the same kind which distinguishes Greek from Roman moulding. It is an extreme delicacy of curve, the substitution of elliptical section for circular, and a wonderfully studious grouping of the hollows, rounds, and arrises, so as to produce a refined and delicate contrast and gradation of light and shade.

The Death is announced of Mr. John Brockbank, City surveyor of Norwich.

## NOTES AND COMMENTS.

AN account of the lake dwellings discovered in Holderness, between Hull and Bridlington, was read by Mr. J. W. DAVIS at the annual meeting of the Yorkshire Geological and Polytechnic Society. He said they appeared to be the most ancient in the British Isles. In digging beneath the platforms, mixed with the natural accumulation of peat there were found large numbers of the bones of animals which had been used as food, charred wood from the fires, implements of stone, rounded stones for pounding and grinding corn, arrow and spear heads, rudely-fashioned objects of bone used for fastening skins round the loins or for personal adornment, and other relics. The excavations were undertaken by the Society, but some help had been given from the funds of the British Association. Indeed, the Yorkshire Geological and Polytechnic Society were pioneers in that sort of exploration, as the attention of the members was turned to tumuli, caves, entrenchments, and other phenomena connected with prehistoric inquiries, at a time when those studies were much less common than at the present day.

WE have often remarked upon the license of the bill-stickers of Paris, who have not the least regard for public buildings or monuments. The police and the higher officials have allowed white and coloured bills to be pasted against new and ancient buildings. The only action is, when the layers of paste and paper become over-thick, to remove them, and thus to make way for a new series. Sometimes after the posters are removed stains of colour remain, which no rain can wash away. The proper course would be to put up a label prohibiting the degradation of buildings, and if offenders were caught, to inflict a salutary punishment upon them. But the authorities act as if the bill-stickers were possessed of immemorial rights. One effort we must admit has just been made to save the Louvre, which has especial attraction for the bill-stickers. Framed wooden panels are placed on the walls for the reception of placards, and it is announced that a penalty will be inflicted on all who stick bills on the masonry. But if a regulation of that kind can be carried out, it is possible also to preserve the buildings from unframed posters, and if so, why has the evil existed for so long a period?

THE subsidences in Northwich and other parts of the salt district have caused not only excitement but serious loss. A meeting was held last week for the purpose of petitioning Parliament to appoint a royal commission to inquire into the subject, when an announcement was made which will give more satisfaction than the prospect of unlimited blue books. Mr. JOSEPH VERDIN, who is known throughout the district for his generosity, has made a gift of two hundred paid-up shares in the Salt Union, Limited, of which the market value is about 28,000*l.* at present, with the intention that the income derived from them shall be applied to compensate people who have suffered through subsidences caused by the pumping of brine. It is to be hoped the subsidences will not go on in perpetuity, but if they cease it will not be difficult to discover many ways to expend the money for the benefit of the district. A memorial for a royal commission was adopted at the meeting.

THE difficulty of blasting rock in the neighbourhood of a town is suggested by a case which has arisen in Dundee. Messrs. YOUNG & Co., of Glasgow, are the contractors for the Fairmuir branch of the Caledonian Railway, which is in progress, and it was necessary to blast rock in order to form the line. In all cases of the kind, people in the neighbourhood become easily alarmed, and it was not surprising that the owners of some workshops applied for an interdict to prohibit the blasting. The Sheriff granted that document, but, as he says, he did not mean an entire stoppage of the rock-cutting. But of course the interpretation put on it was that it was prohibitory. The result was that the works could not be continued, and the navvies would be turned adrift. An application was made to the Sheriff, and it is creditable to relate that he has recalled the obnoxious interdict. The Sheriff maintains that

what he did originally was to prevent the projection of stones and missiles into the workshops of the plaintiffs. "I did not intend," he said, "to stop the use of gunpowder or of any other explosives. I did not intend to stop the defenders' whole rock-cutting operations. All that I intended to prohibit was the reckless carrying on of these operations, and in particular the firing of charges of gunpowder or other explosives without the use of such 'blinding' by brushwood, chains, rope network, wooden plank-ing, or such other protective obstruction as would prevent the stones from flying into the pursuers' property or elsewhere to the risk of property or of life." The Sheriff admits that the depriving men of their employment would be a more certain and irretrievable injury than any that the interdict could prevent. The contractors are not to be blamed if they took the words of the interdict literally. They knew they were liable for damages if they caused injury, but damages *plus* penalties for not carrying out a contract in time is worse than Jedburgh justice.

WHEN the English chapel in the Rue Marbœuf, turning out of the Champs Elysées, was removed about seven years back, in consequence of the street improvements of the district, it was supposed by some of the worshippers that a different cause was at work, and they were not solaced by the price that was given for the building. The new church which is a substitute for it is erected in the Rue des Bassins, near the Arc de l'Etoile, and where once the reservoirs for supplying the fire-engines were to be found. The building is larger and the site is more costly than before, but thanks to Sir RICHARD WALLACE's donation of 10,000*l.*, the financial difficulties were overcome.

ACCORDING to what was said, at the meeting of the Finance Committee, by Sir POLYDOR DE KEYSER, the executive president of the British Section of the Paris Exhibition, the machinery that will appear will not form as impressive a sight as was anticipated. We suppose engineers are weary of exposing their inventions and improvements before people who are more eager to imitate than to purchase. The machinery hall is 1,500 feet long, 374 feet wide, and 160 feet high. Sir POLYDOR called attention to the work which Mr. HUNTER DONALDSON is doing in connection with the decoration. One of the features noted was the great screen which will impart character to the section.

THE sum of two and a half millions of francs has been voted by the Municipal Council for the decoration of the new Hôtel de Ville, Paris. We have already described how the work was allotted, and there are few painters who could claim to have gained a position that would qualify them for the task who have not been gratified with a large or small commission. When completed, the Hôtel de Ville will exemplify the state of French painting in our time. The variety of styles will be remarkable, and it will be found sometimes in one room if not on one wall. Objections were raised against the division of the commissions on that account, but unless the work was given to one artist it is not easy to make out another way to insure unity. The munificence of the Municipal Council is without parallel, and the assignment of the spaces was conducted without any suspicion of unfairness.

WHITAKER'S Almanack has attained its majority, and after so remarkable a youth it would be hard to say what cannot be accomplished by so excellent a servant of the public. Already we possess in the Almanack a book of reference, both wide and varied in range and of unquestioned accuracy. It will generally be acknowledged that information which is sought in vain in larger and more expensive works is to be found in "Whittaker." There is only one short-coming in it, and that is the absence of any recognition of what artists are doing. A review of the year's work in architecture and the subsidiary arts would be a welcome addition to the pages, especially as the dull catalogue of the Stationers' Almanack would not be likely to be imitated. Even without its chapter on art the Almanack is a shilling's-worth which high and low, young and old, should possess.

SECOND SERIES.NO. 51.—MACKONOCHE MEMORIAL CHAPEL, ST. ALBAN'S, HOLBORN.  
[C. H. M. MILEHAM.]

WESLEYAN CHAPEL, HORBURY JUNCTION.

THE above chapel has now been completed about six months. The buildings comprise:—Chapel to seat 200 adults, with small gallery over entrance end for 70 children; organ-chamber, band-room, vestry, heating vault, and front and back entrance, lobbies, stairs, &c., complete. The total cost of the buildings (excluding cost of land and architect's commission) is 1,141*l*. The chapel is situated at Horbury Junction, a small village near Wakefield, and stands upon a good site at the junction of the two main roads. The external walls are 20 inches thick, and are faced with the best Delph wallstones, pitch faced on front elevation, and remainder chopped. The ashlar dressings for the front are of the best white rock from the Holmfirth Quarries, the remainder of ashlar being from a local quarry. The joiners' work is of the best pitch pine varnished, and the roof is constructed on the hammer-beam principle. The windows are all leaden-lights, slightly tinted, with ornamental bosses, &c., in tracery. The plastering is all three-coat work. The slating is of the best quality blue Bangor slates, with dressed stone ridging. The chapel is heated with hot-water piping on the "low-pressure" system. The ventilation and acoustic properties of the building have been carefully considered. The masons' work throughout is an exceptionally good job, and deserves special mention, the builder being Mr. JOHN WAINWRIGHT, of Horbury. The stone carving has been very artistically executed by Mr. J. P. STEELE, of Bristol. The whole of the works have been designed by, and carried out under the superintendence of, Mr. WALTER HANSTOCK, A.R.I.B.A., architect, Batley.

NEW BAPTIST CHAPEL, NORTHCOTE ROAD, BATTERSEA.

THIS building has been recently completed from the designs of Mr. E. W. MOUNTFORD, A.R.I.B.A., of 22 Buckingham Street, Strand, the works being very satisfactorily carried out by Mr. WILLIAM JOHNSON, of Belle Vue Road, Wandsworth Common. The walls are of red brick, supplied by Messrs. RICHARDSON, of Brunswick Wharf, Vauxhall, the roofs being covered externally with "Permanent Green" slates. GREGORY'S wood-block flooring is used. In the chapel seats are provided for nearly 800 people, all of whom have an unobstructed view of the minister. Beneath the chapel is a lecture-hall for 300, infants' and several other classrooms, and kitchen. In a rear annexe are vestries for minister, deacons, and stewards. Separate vestries for men and ladies are also provided. The ceiling of chapel is executed in fibrous plaster by Messrs. JACKSON & SON; the heating arrangements by Messrs. J. L. BACON & Co.; and the gasfittings and other ironwork by Messrs. VAUGHAN & BROWN. The clerk of works was Mr. WILKINSON. The total cost has been 5,400*l*.

In the description last week of the Yorkshire Penny Bank it was mentioned that the lights were supplied by Messrs. HEYWOOD & Co. It should have been Messrs. HAYWARD BROTHERS & ECKSTEIN, of Union Street, Borough.

## BROWN STUDIES.

A REPRESENTATIVE of the *Sunday Times* has succeeded in forcing Mr. Labouchere, M.P., to undergo the ordeal of an interview. The member for Northampton has already made a name in diplomacy, finance, literature, the drama, &c., but according to his own account he is contemplating a revolution in Art. The scheme may be only one of Mr. Labouchere's jokes, but it is worth recording. The reporter relates how, after explaining some political questions, Mr. Labouchere said very gravely to him:—

"There is one thing which I should like you to write in your account of this interview, and that is to disclose a fact which is not yet known to the world. It is for you to communicate to the public that I am the High Priest of Art! I have always had an idea that all other preachers on aesthetics, from Whistler to Ruskin, have laboured in darkness, and that they will not see the light until I lift the veil of mystery which enshrouds Art. After long thought I have evolved entirely new principles, and for my *début* in the realm of Art I intend to devote my energies towards the elucidation of the art of house decoration. In this house I have not been allowed to say a word as to the adornment of it, as from the 'best parlour' overhead to the garrets, and from the dining-room to the basement, Mrs. Labouchere has had full sway, and, like the prophets of old, I am laughed at and gibe at, and bidden to stand aside whenever I venture to air my Art principles."

I may here remark, says the reporter, that the spacious apartment alluded to as the "best parlour" is a marvel of comfort and elegance, and the harmony of colour displayed by the blending together of priceless paintings, old china, silken hangings, Oriental couches, luxurious modern chairs, delicate marble statuary, favourite pictures on easels, rich carpets, and what not, bear tribute to Mrs. Labouchere's artistic skill and taste, which, indeed, is apparent throughout this beautiful home. Nevertheless, the High Priest of Art has other ideas, for he went on to say, "It is usual for most people, if a room be dark, to lighten it by means of pale decorations; or, if the room be light, to subdue it by all that is dark in the matter of heavy-toned paper and hangings. Now, all this is wrong. Put light to light, and dark to dark, and the effect will be pure Art, as well as affording in one house a complete change. When tired of a light room you can repair to a dark, or *vice versa*. The great thing, however, is to have a scale of rooms for real comfort, and gently tone them, from blinding light apartments down to those of pitchy darkness; but take great care never to mix colours throughout the house. Have one colour, and play upon the different shades of it. Now, my mania is brown, and I have bought a nice old mansion in Westminster, which I intend to decorate entirely after my new principle, and all in it will be brown. My friend, Mr. Claude Ponsonby, who has a beautiful eye for colour, has promised to ransack Paris for every new variety of fabrics, wall-papers, carved woods, and pictures—all in brown—and will send them over in shiploads to Westminster Bridge. Those materials in hand I shall work in my new house, and be at home there all hours, when not engaged at the House of Commons, to initiate any visitors who wish to become followers of my new Art principles. The only stipulation is that they come arrayed in brown."

Further inquiries into this wonderful scheme elicited from Mr. Labouchere the fact that he is at present deep in consultation with builders, decorators, and workpeople about his new house. It is to be hoped that the great High Priest of Art will not be done brown himself.

## STANDARDS OF LIGHT.\*

THE great importance attaching to the measurement of light in these days of severe competition between various luminous agents, renders it imperative that the question should be kept well in view, to prevent its being lost in the whirlpool of political changes. To many of the public the question doubtless appears to be one of those with which scientific men like to amuse themselves, but which can by no possibility have any effect on the practical details of our daily life. To show the immense commercial importance of the question in this city of London alone, it is only necessary to put forward the facts relating to the gas supplied by the three large companies, viz., the Gas Light and Coke Company, the South Metropolitan Gas Company, and the Commercial Gas Company. In 1887 the amount paid by the public to these three companies for gas was 3,354,794*l*. Practically the whole of this amount was for 16-candle gas, therefore 209,674*l*. was paid by the public of London for one candle of light. When this item is added to the whole of the gas supply of the United Kingdom, it will be at once comprehended that in this seeming unimportant controversy we have one of the most far-reaching questions of the day; one in fact which, as soon as it is fairly grasped by the public, will have to be speedily settled. Up to the present it may be said that, in spite of the repeated inquiries, reports, papers before the various societies, and long correspondence in the newspapers, the question is still looked upon as merely pertaining to the laboratory of the professional photometrist.

The keen competition between the gas companies and the electricians, which is but beginning to rear its head, and promises to soon become a serious matter, demands a settlement of the value of our English unit, the sperm candle, and the provision of a substitute for it which will at once be reliable

\* From a paper by Mr. W. J. Dibdin, F.I.C., F.C.S., read before the Society of Arts.

in working and capable of multiplication and repetition to an unlimited extent. Looking beyond our own nation, we see the question agitating the minds of conscientious workers in other countries. In France the "Carcel" lamp has held its own since its introduction in 1800, much in the same way as our sperm candles still maintain their pre-eminence here. In Germany the paraffin candle (used, however, in a far more scientific way than are our sperm candles) still holds the field. In America, in this matter, they try all things, and anxiously watch the older countries for guidance.

When gas was unknown, and oil lamps and tallow candles ruled the roast, and the electric light was yet unborn, Bouguer, in 1760, proposed candles as the unit of comparison. In those days there were no official testing stations, and no boards of directors to harass unhappy gas managers. Had Bouguer lived now, it is open to doubt whether he would have been bold enough to have made the same proposition. Sixty-four years later Ritchie proposed wax candles, but does not appear to have worried himself about the rate of consumption. Tallow, paraffin, stearine, and sperm have been all tried, and finally in this country sperm candles, weighing six to the pound, each candle burning 120 grains of sperm per hour, were adopted.

The contradictory results afforded by the various candles and the Carcel lamp gave rise to numerous proposals for substitutes. Amongst these are the four-wick lamp of Potter; Keates's sperm oil lamp; Bunsen and Roscoe's carbonic oxide flame; Crookes's alcohol and benzol flame; Von Wartha's ether flame; Vernon Harcourt's pentane air-gas flame and lamps; Fiddes aperture, Wolf's screened moderator lamp; Hefner-Altenack amyl-acetate flame; Methven's screened Argand flame; Edgerton's screened petroleum reading lamp; Rüdorff's screened Argand flame; Sugg's 10- and 16-candle tests (screened Argands); Dibdin's pentane Argand; Draper's, Zöllner's, Schwendler's, and Violle's incandescent platinum and silver units, and various electric incandescent lamps. For the purpose of ascertaining the quality of ordinary coal gas various devices have been employed, such as the length of a gas flame at known pressures, i.e., "jet" photometers, but these cannot be classed under the head of "Standards of Light."

By a process of the survival of the fittest, only the pentane, the Methven screen, the pentane Argand, and the 10- and 16-candle tests, are now before the public as practical proposals for substitutes for the sperm candle in this country. In Germany the amyl-acetate lamp of Herr von Hefner-Altenack has met with great favour, and it would appear to have a good chance of being adopted as the legal standard. The objection of the English experts to the colour of the flame is so strong, that there does not appear to be any probability of its being adopted here. In France the melted platinum unit, in the form proposed by M. Violle, has met with some favour, but nothing practical has arisen from it up to the present. I tried a modification of this proposal in connection with my experiments conducted under the direction of the Metropolitan Board of Works, in which I melted platinum foil by the oxyhydrogen blow-pipe flame, and took the light emitted at the moment of its melting as the indicator. This system was followed up by the Standards of Light Committee of the British Association, and elaborated by Mr. H. Trueman Wood, the secretary of this society, who arranged the foil so that it could be melted by an electric current. The British Association Committee also tried a suggestion of Professor Dewar, which provided for the end of a thick rod of platinum being kept in a molten condition by the oxyhydrogen flame, and, while in that condition, being used as a standard after the manner of the Methven, a screen with a small circular aperture being placed immediately in front of the molten bead of platinum. None of these methods, however, gave reliable results, and there does not appear to be much hope of such a standard ever finding favour in this country.

The Standards of Light Committee of the British Association for the Advancement of Science reported this year that, in their opinion, Professor Violle's molten platinum standard is not a practical standard of light, although they were quite prepared to agree to the adoption of the light emitted by a square centimetre of molten platinum as a unit, but not as a standard of light.

Having arrived at the conclusion that the present legal standard is unreliable, it is necessary to inquire into the merits of the various proposed substitutes. Of these the pentane air-gas standard of Mr. A. Vernon Harcourt undoubtedly holds the highest rank. This was first introduced in August, 1877, when Mr. Harcourt read a paper upon it before the Physical and Chemical Sections of the British Association, at their meeting held at Plymouth. On April 8, 1879, Mr. Harcourt forwarded to the Board of Trade a letter accompanied by a statement of a series of tests made with the candles and the new standard. In consequence of this communication the Board of Trade appointed the committee to which I have already referred, who, after a very careful examination, reported that, "Compared with the sperm candle, Mr. Harcourt's air-gas flame is exact and trustworthy as a standard of light."

The conclusions as to the fitness of the pentane air-gas as a desirable unit, arrived at by the Board of Trade Committee in 1887, and by myself in 1885 and 1887, have since been confirmed by the Standards of Light Committee of the British Association, who this year recommended its adoption.

Having now arrived at the point at which candles are shown to be untrustworthy, and a suitable substitute found in the pentane air-gas flame, aided, for practical purposes, by the pentane Argand, it may be of interest to glance at the position of the question on the Continent. In presenting a Report of the Committee on Candles to the twenty-eighth annual general meeting of the German Gas and Water Society, in September last, Dr. Krüss stated that the committee thought to have fulfilled their instructions by establishing the German Society's paraffin candle, which had for the last year been manufactured under the society's direction at the works in Waldau; and that the society had determined no longer to issue six to the pound but ten, in order to obtain a length of candle more suitable for practical use. Each single candle was provided with a wick in perfectly central position, which is more easily accomplished in the shorter candle than in the long one. Care had been taken that the new candles have exactly the same photometrical value as the former ones. While the work of the committee had been devoted to the control of the production of the standard candles, and to supplying these to the consumers, they had occupied themselves with the amyl-acetate lamp, and had already come to the conclusion that it was an extremely comfortable standard for every-day use. This decision had been subsequently confirmed. From the results of a number of tests made by the members of the society generally, it was agreed that for daily use for the present there was no better, more practical and comfortable, and less time-consuming means for light measuring. It appeared, however, that the proportion of the intensity of the lamp to the different candles had not been accurately determined. The intensity of the German Society's candle was variously stated to be 1.2, 1.234, 1.21, 1.26, 1.12, and 1.20 amyl-acetate lamps with 40 mm. height of the flame. Still greater differences had been found when comparing the English candle with the lamp. It was evident that further close and continuously systematic trials were necessary to determine its exact value. From a series of experiments conducted by Dr. Liebenthal, of Hamburg, it appeared that the measurements of the wick tube, and consequently the diameter and length of the wick, need not be adjusted with extreme accuracy, but that the height of the flame was very important, and that the mean variations between two amyl-acetate lamps come within one per cent. The committee had therefore resolved, in conformity with the experience up to the present, that the steadiness and easy application of the amyl-acetate lamp, even in its present form, recommends it as a suitable means of comparison for light measurements, and that further trials are necessary to determine the proportion between the intensity of the amyl-acetate lamp and that of the candle. It was therefore proposed to constitute the Committee on Candles, a committee on light measurements to make these trials together with suitable experts, and that the Physical and Imperial Technical Institute of Charlottenburg be requested, through the Imperial Board of Home Affairs, to lend their co-operation in the investigation.

This decision is of great importance. From the results of the very numerous tests made by myself and others with the amyl-acetate lamp, it is evident that its convenience and steadiness is all that can be desired, but, as I have stated, its colour is against it in the opinion of the English experts. Could this be overcome, it would be a very convenient standard, but all efforts up to the present have failed to produce a light of the character of that given by the pentane and candles at their best. From my experiments I found that the forty millimetres height of flame was too low, but on raising it to fifty-one millimetres, or two inches, it gave results identical with the average English candle as determined by both the pentane and Methven screen.

I am informed by Dr. Krüss, of Hamburg, that while they agree that the colour of the amyl-acetate lamp is very unfavourable, they did not know of anything better, and therefore had to put up with it. They are now trying the improved pentane lamp of Mr. Harcourt, but the experiments are not yet concluded.

One of the objections put forward to a change of standard in England is, that no general desire has been expressed to that effect. It has been already shown that the authorities of the Board of Trade—the controlling authorities for gas-testing purposes in London—the gas interest generally, as represented by the Gas Institute, and the British Association, have all joined in one condemnation of the existing candle, and in demanding an alteration, and, with one exception, that such alteration should consist in the adoption of Mr. Harcourt's pentane air-gas flame. It has also been said that no alteration can be made in London without affecting the country generally. If the regulations applying to the candles were general, that would be a strong argument, but at the present moment there are virtually two different standards in use. In the Metropolis Gas Act

the standard candle is defined as "sperm candles of six to the pound, and burning at the rate of 120 grains per hour." In the instructions of the Gas Referees it is prescribed that the candles shall attain their "normal rate of burning," and no mention whatever is made of their *manner* of burning. In the Gas Works Clauses Acts, 1871, however, which applies to the country outside the metropolis, it is specifically laid down that the tip of the wicks shall be glowing and slightly bent, and thus a distinct condition is indicated. True, most photometrists decline to use the candles in any other manner, but it has been repeatedly argued, on behalf of the gas authorities, that an examiner has no discretion provided the consumption of the sperm is within the prescribed limits, so that a test is a perfectly legal one when the wick is upright, and the candle consequently giving less light, with the result of indicating a higher value to the gas than it otherwise would have. Such a condition of things does not argue well for the maintenance of uniformity in the manner of testing the value of the gas supplied in such enormous volumes to the public. If those outside the metropolis are satisfied with the better protection they now have, it is no reason why a less sufficient protection should satisfy the inhabitants of London. It cannot be imagined, however, that the general public of the country are aware of the present defective condition of the question. In all other matters affecting the commercial transactions of daily life, the most stringent regulations are in force to maintain almost mathematical accuracy in the various weights and measures used. In the matter of light alone the utmost laxity prevails, and when it is considered that such vast interests are at stake, it seems almost inconceivable that the legalisation of an accurate standard of light, such as can now be obtained, should be delayed for a moment longer than that required to take the necessary steps.

### THE AGREEMENT OF COLOUR THEORIES WITH PRACTICAL EXPERIENCE.\*

**A** KNOWLEDGE of the scientific rules of colour seems to me much more essential in decorative than in picture-painting. In the latter an artist has generally his subject before him; but in decoration and the applied arts, he has, as it were, to invent his colour scheme from his knowledge of colours, all of which are influenced by definite physical laws. It is well known that in decorations, especially those on a large scale, it is impossible for persons ignorant of the laws of colour to judge of what the ultimate effect will be while the work is in progress. Portions only of the colours to be applied are introduced at first, the hues of which will be very materially changed when the remaining colours are added and the scheme is complete. In my own applications of colour I have invariably found that, by subjecting my schemes to scientific rules, I have not only avoided errors, errors easily fallen into in so relative a subject as colour, but I have certainly attained higher results than I could possibly have done without them, and not had to make repeated alterations, entailing additional expense, so often found necessary as a scheme drew near completion.

Perhaps the most important principle, and that upon which all others depend, is that there are three primary colours—three colours from, or by, which all other colours may be obtained, innumerable as the number of hues, tones, and shades are. Though the three primaries produce all other colours, yet they themselves cannot be obtained by any admixtures. Artists and physicists both agree as to their being three primary colours, but they differ as to the particular colours.

The artist finds, from practical experience, that almost all colours may be obtained by mixtures of three simple or elementary pigments, in different combinations or degree. The physicist explains that all colours are due to the excitation of three simple or elementary nerves, or sets of nerves, in the retina of the eye, by the different lengthened vibrations of which all white light consists. The artist names the colours of the three primary pigments, red, yellow, and blue. The physicist generally names the three primary sensations, red, green, and violet.

It appears, therefore, that there are two sets of primary colours: first, the colours of the primary pigments; secondly, what may be termed the colours of the primary sensations. It is essential to note this distinction—the first set has to do with pigments, or objects causing certain sensations; the second set has to do with those sensations themselves.

It will be observed that, with the exception of the red, the colours of each set are differently named. That red should be the only colour common to both seems very remarkable, and at once suggests the inquiry whether the hue of red in each case is the same or different? Referring, in the first instance, to the two other colours in each set, we find that they are not common, but are the very reverse. They are not only differently

named, but the one set contains the mean colour between two colours of the other set, and is therefore opposite, or complementary to the third, as may be best illustrated in diagrammatic form:—

The triangle with the strong outline represents the three primary pigment colours—that with the faint outline represents the primary colour sensations.

Thus green is the mean colour between, or may be obtained by the mixture of the primary pigments blue and yellow, and is complementary to the remaining primary red. Violet is the mean colour between, or may be obtained by the mixture of the primary pigments red and blue, and is complementary to the remaining primary yellow. Any one who has mixed pigments knows these assertions to be facts. Yellow is the mean colour between, or may be obtained by the combination of red and green light, and is complementary to the remaining primary sensation, violet. Blue is the mean colour between, or may be obtained by the combination of green and violet light, and is complementary to the remaining primary sensation, named by the physicist red. Physical experiments have proved these statements.

The term red, though common to both sets, cannot be the exact colour obtained by two different combinations, or be produced by the mixture of itself with another colour; such a suggestion seems absurd. It cannot, if we are to understand a distinct hue by the name, be the mean colour between itself and both violet and yellow; that is, the particular hue of red will not remain the same when violet or yellow are added to it. The difference of hue between a red and violet mixture and a red and yellow mixture would be very considerable indeed, about as far apart as two reds could well be, as shown on diagram. Yet if the two other colours of the one set, when combined, produce one of the colours of the other set, it seems reasonable to conclude that the remaining colour red should, when similarly combined, produce a similar result. According to this, however, red and violet produce red, and red and yellow produce red! Two different combinations seem to produce the same result, which is impossible, for the two resulting hues would be, as I have just pointed out, as different as they well could be under the general name of one colour.

Red, then, seems to be a very general and ambiguous term; for it is evident that the hue of red in the one set is very different from that in the other, that the artist's primary red pigment and the physicist's primary red sensation are totally dissimilar—the one being of a crimson or violet hue, the other of an orange hue. It seems desirable, therefore, that either the artist or the physicist, or both, should adopt some more definite term to describe a colour in which they can only agree in name and not in fact; for much confusion and apparent antagonism between the art and science of colour, as regards the primary colours, has already been occasioned by this indefiniteness of meaning.

The ambiguity regarding the names of colours is well known, and to it much uncertainty may have been due; indeed, ambiguity in so relative a subject as colour can hardly be avoided. It requires but a very elementary knowledge of colour effects to know that colours may be made to appear very different by changing, not themselves, but those with which they are associated or juxtaposed. Red may be made to appear orange or crimson, green may be made to appear blue or yellow, and so on; it entirely depends on what colours are put next to them. Chevreul's book is full of such instances. It is not, therefore, at all extraordinary that colours should be misnamed when they have such chameleonlike properties. A colour also appears very different under different conditions of light. Two rooms, for instance, coloured exactly alike, but one having a southern and the other a northern aspect, would appear very different. The yellow light of gas has, of course, a marked effect, as also the coloured light of stained-glass. Ambiguity, however, in colour is not entirely due to these causes. Without even taking into account

\* From a paper by Mr. G. H. Morton, jun., read before the Art Congress, Liverpool.

the variableness of the colour sense in different individuals, which is undoubtedly very great, there is another important point, and that is the very gradual way by which the most opposite colours may be connected. There are no distinct lines, as it were, between colours. It would be difficult, indeed impossible, to point out exactly where the red, green, or violet of the prismatic image began or ended; and when out of the innumerable perceivable tints we have to name three, or six, principal colours, it is impossible that the exact hue of each of these colours can be distinctly and definitely described. Only an approximate idea can therefore be given. Of reds we have orange and crimson reds, and all the hues between these two extremes, yet all are reds; of yellows we have orange and greenish yellows, yet all are yellows; and of blues we have greenish and violet blues, yet all are blues. The six principal colours only have been named; but when it is borne in mind that it has been estimated that the eye can distinguish not less than two million distinct tints of colour, the difficulty of determining their exact hues will be at once understood.

It is desirable, however, that the particular hues of the primary pigment colours and the primary sensations of colour should be as nearly as possible defined, so that we may ascertain their relationship to each other, and also whether there is a difference of hue between the so-called primary red pigment and the primary sensation named red.

The hue of a primary pigment is decided by that hue which will mix with both of the other primary pigments—in other words, with the greatest number of other colours, and still retain brightness, or not cause the compound colour to become "dirty" or "muddy." This is ascertained by practical experience rather than by physical experiment. Most persons know, for instance, that blue and yellow pigments when mixed together produce green, and that blue and red produce violet. The question is, what particular hue of blue will produce the most brilliant green and violet when mixed with yellow and red respectively? It is a simple matter to get one hue of blue that will produce a good green, and another hue that will produce a good violet, but we have to decide on one particular hue that will mix well with both.

Generally speaking, the hue of each primary pigment tends towards blue, or away from red. The primary blue pigment is of a greenish rather than of a violet hue; this particular hue of blue mixes with both the other primary pigments, yellow and red, with less loss of colour than a violet-blue would do. Let us practically apply this: let Prussian blue represent the primary greenish-blue, and ultramarine the violet-blue. It will be observed that Prussian blue mixes well with red on the one hand, and with yellow on the other, producing tolerably bright violet and green. Ultramarine, however, though it mixes even better with the red (because being a violet or reddish blue it is naturally more analogous or sympathetic with red), at once loses colour, and produces a less bright or "dirty" effect when mixed with yellow. Hence the hue of Prussian blue is nearer the hue of the primary pigment blue than the hue of ultramarine. The primary blue pigment is consequently of a greenish rather than a violet hue.

The hue of the primary yellow pigment is in like manner that particular hue of yellow which will, when mixed with blue and red respectively, produce bright green and orange. A yellow that has a slight greenish rather than an orange tint. King's yellow approaches, as near as most yellow pigments, the hue of this primary; it mixes well with both blue and red, producing tolerably bright green and orange respectively. A warm or reddish-yellow mixed with blue results in a "dirty" green or olive, consequently a yellow the reverse of this, a cool, slightly greenish-yellow, is the hue of the primary pigment yellow.

The primary red pigment, with which we are most concerned, because of its being the name given by artists and physicists alike to one primary in each set, is of a crimson or violet hue, the opposite of scarlet or orange. Rose madder or crimson lake are, for instance, nearer the hue of this primary than vermilion. If we mix any blue pigment with vermilion we at once neutralise the colour, and do not obtain bright violet or purple. We only obtain bright combinations by mixing it with yellow, the primary pigment nearest to it in prismatic order, and produce bright orange hues. With a bluish red, however, as rose madder, not only is it possible to obtain bright effects when mixed with blue, the primary nearest to it in prismatic order, but when mixed with yellow, the primary most opposite or farthest prismatically, bright orange hues result. Consequently, a red of a bluish hue, as represented by rose madder or crimson lake, indicates the more exact hue of the primary pigment red.

Blue, yellow, and red, of the particular hues I have endeavoured to describe and illustrate, are therefore the three primary pigment colours.

There is always a possibility of error in describing a colour by reference to a particular pigment. Pigments, bearing the same name, not infrequently vary very much in hue from one cause or another. The colour pigments I have enumerated are

given as the nearest to the particular hues I wish to describe. Coloured plates in books on colour are also often very misleading, due no doubt to printers' inexactness, or the fading of some of the colours.

In all practical mixtures the primary pigments would not necessarily be employed more than any others. The two colours to be mixed would be chosen as nearly as possible in hue. If an artist, for instance, desired a brilliant orange, he would obtain it by mixing a yellow and red as similar in hue as possible, as near together in prismatic order as could be obtained, say any warm yellow and vermilion; to use a greenish yellow or bluish red, as lemon chrome and lake, would of course introduce some blue, and thus tend to neutralise the compound orange, and make it dull or "muddy."

That the primary pigments should be of bluish hues is scientifically explained by the vibratory theory of light. It is well known that all colours are caused by vibration of different strengths affecting the eye; the stronger vibrations excite red, the weaker blue or violet. In combinations of colours, the weaker vibrations are more easily subdued. In mixing rose madder and yellow, the weaker blue and violet, or neutralising colours, which may be said to be present in the madder, are overcome and destroyed, and a bright secondary orange is the consequence. On the other hand, if vermilion and blue are mixed together, the stronger and more powerful vibrations of red and yellow assert themselves to such a degree that the weaker blue is neutralised, and a "dirty" colour having some slight resemblance to violet is the result. In this case the three primaries—red, yellow, and blue—are combined, the result of which, of course, produces a neutral or dull compound colour tinged with the predominating colours red and blue, which together make violet.

All colours are properly sensations, caused by the action of light on the retina of the eye. It is now, I think, generally admitted that there are three sets of nerves, and that each of these when excited produces a sensation we name colour. Hence colour does not exist outside ourselves, and, strictly speaking, it is as incorrect to allude to a pigment as a colour as it is to allude to any other sensation as being the object causing it. Instead of naming any object, say red, it would be more exact to say that the object caused us to experience the sensation of red, for often the object itself is the very opposite colour of what it appears to be. A colour object, or pigment, absorbs some of the white light shed upon it, and rejects the remainder, the rays rejected affect the eye, and excite there the sensation we name colour. In the case of a red pigment, all the blue and green producing rays have been absorbed, and the rejected rays excite red. No doubt it is much simpler to refer to pigments, or colour objects, as actually being the sensations rather than causing them, and many persons seem to have had great difficulty in grasping the distinction.

The primary sensations are, therefore, the only primary colours, properly speaking. They are generally named violet, green, and red. The violet is less red than is commonly conceived by that term; a warm ultramarine perhaps best describes it. Maxwell selected a violet-blue between the lines F and G on the spectrum, which, as Professor Rood points out, is represented tolerably well by artificial ultramarine. Benson in his "Science of Colour" names this primary blue, but as most authorities adopt the term violet, this name may, I think, be accepted as most correct.

The primary sensation green is represented in pigments by emerald green. There seems little difference of opinion as regards this colour.

The primary red sensation is distinctly an orange-red or scarlet, and, though Helmholtz selected a red not far from the end of the prismatic image which could scarcely be named orange, Maxwell adopted a red which in the spectrum lies between lines C and D. This is a scarlet-red, as Rood states in his "Modern Chromatics," with a tinge of orange, and is represented by some varieties of vermilion. Benson gives vermilion as best illustrating this primary red sensation, and perhaps all the authorities I have consulted describe a red the reverse of a crimson or violet-red. This primary sensation, therefore, appears to be the very opposite in hue from the primary red pigment. It is very evident that the idea conceived by the term red in the one set of primary colours is not the same as in the other set.

In order to avoid confusion a different name might be substituted for this colour in each set, based upon their particular hues, as crimson the primary pigment, and scarlet the primary sensation, which terms I adopted in a former paper\* on this subject. To ignore the old association of the six principal colours, however, and the omission of the term "red" altogether seems undesirable if it can be avoided.

Before attempting to suggest new terms, however, it is necessary to consider the secondary colours. In pigments they are usually, and I think correctly, named orange, green, and

\* "Colour Harmony." Paper read before the Literary and Philosophical Society of Liverpool during its seventy-second session.

violet, and denote the resulting colours from the mixtures of two primaries, red and yellow, yellow and blue, blue and red respectively. All the ambiguity relative to the primaries is also peculiar to these secondary colours, and indeed to all colour terms.

With the exception of the orange, the names of these secondary colours are the same as those given by physicists to two of the primary sensations; and as I have already explained that the primary sensation red is distinctly an orange red, it may, I think, be reasonably concluded that the colours of the primary sensations are the same as the secondary pigments, but much lighter and brighter. The primary pigments will therefore be the same as the secondary sensations. So-called secondary sensations of colour—that is, when two sets of nerves are excited simultaneously—are generally named yellow, sea-green or greenish blue, and pink. They are respectively produced by orange and green, green and violet, and violet and orange. The combination of two pure coloured lights naturally produces a much lighter and brighter colour, hence secondary colour sensations are much lighter—doubly as light as a primary. In order to compare them with a pigment, it is necessary to lighten the pigment by the addition of white. Upon doing so we find that red, yellow, and blue of the hues I described in the early part of this paper as representing the primary pigments respectively produce pink, pale yellow, and greenish blue, the hues of the secondary colour sensations.

A comparison might also be made by darkening the secondary colour sensations by interposing darkness.

If the foregoing is correct, it follows that the colours of the one set are complementary to the colours in the other, as may perhaps be best shown in tabular form:—

Primary colour pigments (secondary sensations).		Primary colour sensations (secondary pigments).
Blue . . .	complementary to . . .	Orange.
Red . . .	“ . . .	Green.
Yellow . . .	“ . . .	Violet.

The evidence of this relationship distinctly supports the theory that the hue of red in each set is and must be quite opposite. The colour complementary to, or required to neutralise blue, a compound of green and violet, would of necessity be of a totally different hue from that required to neutralise green, a compound of yellow and blue—the blue requires an orange, the green requires a red. A secondary colour being a compound of two primaries also supports it, for the resulting colour from the combination of violet and orange cannot be the same as that obtained by the mixture of yellow and red. The former, if produced without loss of light—that is, by the combination of violet and orange light—produces a pale bluish-red or pink; the latter by combination of yellow and red light, or by pigment mixture, produces orange. The primary pigments, therefore, appear to be the same colours as the secondary sensations, and the primary sensations appear to be the same colours as the secondary pigments, or rather approximate to, for even the most brilliant pigments are dulness itself compared with actual colour light.

As a rule, in all combinations of colour light, and of colour pigments, the opposite effects of light occur. Combinations of two colour lights produce a lighter effect; mixtures of two pigments usually produce a duller effect. The first might be called positive, the second negative colouring. The physicist in all his experiments has the actual light to operate with, and he finds that what he names red, but which I submit would be more correctly termed orange, green, and violet, produce perhaps all varieties of colours; hence he names these the primary colours. When an artist, however, mixes two pigments together, he has not the actual light to deal with—he has not orange, green, and violet-producing rays, but he has instead three pigments which have absorbed them. The colours of his primary pigments will necessarily be such as have absorbed these colours. The colour of the pigment which absorbs orange is blue, the pigment which absorbs green is red, the pigment which absorbs violet is yellow. Blue, red, and yellow are, therefore, the primary pigment colours, and are the reverse and opposite of the primary sensations orange, green, and violet.

It is possible that the term red, as commonly understood, does not convey to our mind the particular hue of either the primary sensation or the primary pigment. It has been made to do duty for both, and therefore exactly described neither. It denoted a colour too orange in the first case, and too violet in the second. The question, therefore, seems to be whether we should do away with the use of the term altogether, or give it a more definite and perhaps different meaning from what we are accustomed to do. To alter long familiar names is bad policy, and for myself I should prefer to understand by the term red a colour of a more violet hue than I formerly associated with it. We might, of course, add the prefixes crimson and orange as adjectives; but did we do so, it would be equally justifiable to add qualifying terms to the other colours, as an orange yellow, greenish yellow, and so on. I would, therefore, submit that by the term red is meant a colour of a more violet than orange

hue, best represented perhaps by the pigment rose madder; that the primary pigments be still named, as they have always been, red, yellow, and blue, and that the names of the sensations caused by the action of light on the three sets of colour appreciating nerves, be named orange, green, and violet.

By adopting different names to each set of primary colours, the antagonism often asserted as existing between the practical and physical facts of colour falls to the ground—indeed, science supports the knowledge of the artist gained by experience. The colours of either set—the primary pigments red, yellow, and blue, or the primary sensations, orange, green, and violet—when combined in certain relative proportions, produce harmony or neutrality.

### ANTIQUITY IN AMERICA.

IN America, comparatively a new country, any structure antedating the Revolution is “old,” consequently of interest to the Americans. The stone arch “Choate Bridge” spanning the Ipswich River at Agawam was built in 1764, and is one of the oldest, if not the oldest, stone arch bridge in the country. According to the *Boston Transcript* the builder was Judge Choate, a member of the Colonial Government of Massachusetts for many years and the commander of the 8th Massachusetts Regiment at the siege of Louisburg in 1745. In 1760 he was treasurer of Essex Co., and as such he superintended the outlay of the money appropriated by the county for this bridge. He advocated stone as the material, and planned the bridge against the wise sayings and head-shakings of his doubting contemporaries. The arches are low and the spans are about 35 feet each; but the Judge did not propose that his bridge should fall, and consequently the amount of stone used was enormous for the work to be done. He took the granite as it came from the ledge, unmarked by any tool; but the stone for the arch was carefully selected, and the work stands intact to-day as a monument to his ideas of a permanent structure.

“Antiquity after a time has the grace of novelty.”—HAZLITT.

#### GOETHE'S CRITICISM ON THE HEAD OF ONE OF THE HORSES OF NIGHT IN THE BRITISH MUSEUM.

AS Carlyle was unkindly treated by nature in being sent into the world without any faculty that would enable him to appreciate the Beautiful, it naturally followed that he must make little of the power of which he was deprived. Goethe and Schiller were esteemed by him as great men; nevertheless he compared their efforts to define the principles of art to the wanderings of unfortunate people who were deluded by will-o'-the-wisps and floundered in quagmires. All that Carlyle says about art reveals his own shortcomings. Goethe, on the contrary, was not curtailed in his mental proportions by nature; he was a grand type of the “all-round man,” and as such he was attracted towards the Beautiful. It suggests the range of his sympathies when we find him in Weimar commenting on the agitation which was going on in England in 1816 for the acquirement of the Elgin marbles.

One of the accepted authorities in England at that time was Richard Payne Knight. He considered the finest of the Parthenon marbles as not entitled to be placed in any but the second rank of sculpture, and if sold in detail the prices would not, he said, realise more than about 10,000*l.*, although he valued the collections as a whole at 25,000*l.* His appreciation of the head which was supposed to belong to one of the horses of Night is seen by the price he fixed on it, viz., 250*l.*, admitting, however, that it was “very fine.” Visconti described the head as being of the finest possible workmanship, and as having that admirable expression of life which great artists only are capable of bestowing on their imitations of nature. The most enthusiastic of the advocates for the purchase of the statuary was the unfortunate B. R. Haydon, the painter, and it followed that he must be in opposition to Payne Knight.

It was characteristic of Goethe that seeing so much variance about a definite subject he should try to discover where the truth lay. As the horse's head from the Parthenon had been compared with those of the horses upon St. Mark's, Venice, which once stood on an arch in Rome, he compared the two kinds of work in the article which follows:—

“A Mr. Payne Knight, who seems to be a man of much influence, had expressed a very unfavourable opinion respecting the Elgin marbles; denying them to be possessed of any merit, and maintaining they were of the age of Hadrian, and executed by common workmen, who hardly deserved the name of artists.

Mr. Haydon, an able artist, maintains, on the other hand, that Mr. Payne Knight knows nothing at all of art; and in fact, if he has really delivered the opinions attributed to him, we can hardly help suspecting as much. Mr. Haydon, however, in his well-meant zeal for the figures carried off from the Parthenon, has allowed himself to go too great lengths, when he maintains that the Elgin marbles are superior to all other works of art in existence; that they will cause the old antiques to be forgotten. He rather injudiciously observes that if these marbles had been lost, there would have been as great a blank in the progress of art as there must have been in philosophy if Newton had never existed.

"Mr. Haydon has entered into a comparison between a large horse-head of marble from the Parthenon, and a head of one of the four bronze horses at Venice, which, agreeably to common report (for which, however, there is no authority), he calls the horses of Lysippus. Mr. Haydon, however, does not enter on the subject of the name, but merely compares the two works of art, and, as might be expected from his Essay against Mr. Payne Knight, he gives a decided preference to the Athenian head. To the Venetian head he assigns an incorrect shape: condemns the position of the eyes, and affirms that the jaw is of an undecided form. When we view the two works in profile, the Venetian head does appear shut, and somewhat ox-like, the nostrils too are not in the right place, and the upper lip does not project sufficiently; while the Athenian head has all the character of a spirited horse of noble race. Not content, however, with extolling this noble work of art, Mr. Haydon has unnecessarily and unjustly depreciated the Venetian horses.

"We enjoy the advantage of having beside us very fresh casts of the two heads, the subject of Mr. Haydon's comparison, and can therefore enter into a close examination of his assertions.

"The Venetian head and the Athenian are both admirable works, and each excellent in its way. A slight acquaintance with the monuments of ancient art will enable any one to perceive a striking difference of style between them. In the Athenian head the prevailing character is sublimity. The Venetian bronzes again are executed in a more soft, flowing, and ornamental style, and undoubtedly in a later age.

"The Athenian horse is higher, more powerful, snorting, with a startled look; the eyes are rounded and projecting. The ears hang back, and the mouth, which is opened, seems to be exerting itself violently to get forwards, but to be powerfully kept back. When we look at the workmanship, we everywhere observe antique simplicity, and the most praiseworthy diligence and truth, but at the same time a little stiffness. For example in the mane: line is regularly laid on line, parallel to each other, and of the same depth; and in the bend of the throat, one fold of the skin is placed beside another, with hardly any variety. The execution in general merits great praise, the muscles and bones are represented with great knowledge, expression, and truth. The eyes are admirably formed and perfected; the forehead is broad, flat, and bony; the nostrils widely extended from the current of breath; the upper lip, as if animated and in motion. Though the marble has been much injured by the weather, from the nose upwards to the forehead, we perceive, notwithstanding, the traces of veins originally existing there.

"In the head of the Venetian horse, which we have now before us, all appears much smoother, and more ornamental; the outlines are more flowing, and run more softly into each other; the animal is represented much more tranquil and gentle; as pleased and glad, and willingly obeying the rein. The master has conceived the whole in his milder character; the proportion of the parts is suitably selected, the eyes have a softer look, and though the pupil is powerfully marked, they are not so round, not projecting as in the Athenian head, but kept flatter, drawn more backwards, especially towards the apple of the eye under the eyelid, which covers it considerably. It cannot be denied that there is some deviation from nature in this part, and an approximation to the shape of the human eye. The ears are in playful movement, the right back, the left somewhat bent forward, the nostrils, suitably to the general character, less opened, less snorting, but like the upper lip not so natural, nor so animated as in the Athenian figure.

"With respect to the execution, the most striking difference is also perceptible between them. In the Venetian horse (though everything is generally more strictly marked in bronze works) the hair of the mane is much more ornamental, less stiff, and the lines more varied; and the same may be said of the folds of the skin in the throat. As the prevailing character is the soft and agreeable, the muscles and bones are less determinately marked, and the transitions milder and more flowing. We have pronounced no opinion respecting the relative merits of the two works, but merely pointed out the diversity of style, and consequently their different ages. More than this ought not to be attempted, and the one should not be eulogised and the other depreciated; for both are admirable, and to censure either the one or the other ill becomes us, as each is far beyond the powers of any artist of the present day. We cannot, however, conceal that our inclination is more particularly directed

to the Athenian work, and with respect to it we might perhaps agree with Mr. Haydon. But we would merely recommend it to him, and still more to German connoisseurs, to reflect that in order to praise what is admirable it is not necessary to load other works, which are also admirable in their way, with faults which do not belong to them."

The article will give a good notion of Goethe's critical method. In the first place he abominated rows, and could not therefore approve of the heat which Haydon displayed in the controversy. Then he was analytical, as we can see, and contrasted detail with detail. But he was not the man to undervalue a work which was placed second. Indeed Goethe was never over-enthusiastic about the masterpieces of art or literature. Their merits might be very great, but on that account he knew there was a prepossession that they were unsurpassable. Goethe had too much faith in humanity to lose confidence in the possibilities of genius. For that reason he insisted on audacity being a strong quality with an artist which would not only enable him to follow his own bent, but to resist all efforts to hamper his talents. At the same time he counselled the closest communion with the masters of art, and discriminated between following art in one's own way and following art's way. But no man could be more opposed than Goethe to the notion that it is possible to produce a work of art by recipes.

In judging his criticism on the horse's head in the British Museum it is well to remember that Goethe had only a plaster cast before him, which could not convey any notion of the bony character of the original.

### GENERAL.

**The Duke of Westminster** has presented Turner's *Dunstanborough* to the National Gallery of Melbourne.

**The Exhibition** of the Royal Society of Artists, Birmingham, will close on Saturday, January 5.

**The West Window** of Exeter Cathedral is to be filled with stained-glass, at a cost of 1,000*l.*, as a memorial of the late Earl of Devon.

**A Reredos**, designed by Mr. J. G. Crowther, has been placed in St. Saviour's (Cathedral) Mission Church, Cheetham.

**A Paper** on "Art and Architecture" was read by Mr. J. W. Knowles, art decorator, at the monthly meeting of the York Architectural Association.

**Photographs** of the walls of the Walker Exhibition Rooms, Liverpool, showing the pictures, are to be preserved by the Corporation Art Committee for future reference.

**A Reredos** in stone has been designed for the parish church of St. Mary de Crypt, Gloucester, by Mr. F. S. Waller, and executed by Mr. Frith, of Gloucester. The three central panels of coloured mosaics, designed by Mr. Westlake, were carried out by Messrs. Salviati & Co., at Venice.

**Mr. J. A. Reeve** having completed his measured drawings of Fountains Abbey, the reproductions of these will shortly be issued to subscribers.

**The Dumbarton** Dean of Guild Court on Monday approved of plans for the erection of a cottage hospital to contain eight beds.

**Mr. J. H. Middleton** is to deliver at the Royal Institution four lectures on "Houses and their Decoration, from the Classical to the Mediæval Period."

**The old Tile and Pottery Works** at Portland Road, Notting Hill, are to be converted into a recreation ground for residents in the district.

**A New Hospital** for infectious diseases has been erected at Faversham, and special attention has been paid to the ventilation, the latest improved form of Messrs. Robert Boyle & Son's patent self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

**A Deputation** from the Glasgow Corporation has paid a visit to Edinburgh. The powers of the authorities in Glasgow in dealing particularly with insanitary houses, it seems, differ materially from those at the disposal of the local authority of Edinburgh, and the object of the visit was, it is understood, in view of a probable application being made for additional powers, to get information on the spot as to the way in which the work is carried out.

**The Pictures** lent to the Birmingham Corporation Art Gallery by the Duke of Norfolk and the Duke of Westminster have now been removed, and their places have been supplied by a number of works belonging to the Belhus collection, lent by Sir Thomas Barrett Lennard, for which room could not previously be found. They include examples of Guercino, Romney, Hoppner, Berghem, De Heem, Sir Peter Lely, Sir Godfrey Kneller, and other painters of note.

**Mr. John Livingston**, of Musselburgh, has offered a sum of 500*l.* as the basis of a fund for the building of a new hall for Inveresk parish church. The hall is to be for congregational purposes, and will be built away from the church.

P. JOLIN & CO., Narrow Wine St., Bristol.

THE Edinburgh and Leith master builders and operative masons have entered into an agreement that 7d. per hour be the uniform wage for one year in Edinburgh and Leith from March 1 next.

A REREDOS in oak, as a memorial to the late rector, has just been fixed in Buriton parish church, Hants. The work has been executed by Messrs. Jones & Willis, of London and Birmingham, from the drawings of Mr. F. W. Cave, architect, London.

THE new school, Tyldesley, is warmed and ventilated by means of Shorland's patent Manchester grates, supplied by Mr. E. H. Shorland, of Manchester and London.

A FIRE occurred on Friday night in the extensive premises of Messrs. Bissett & Sons, contractors, of Sheffield. It was found that the fire originated in a large central building, in the lower portion of which was stored valuable timber. The upper part was used as the joiners' shop, and was filled with machinery. The building was gutted. The loss, which amounts to many thousands of pounds, is covered by insurance in the Alliance. The tools of the men were destroyed.

MR. DANIEL WATNEY, the arbitrator in the case of Reilly v. Manchester Ship Canal, which occupied seven days at Manchester, has issued his award. The inquiry was held to assess the value of the property at Manchester known as the Pomona Palace and the Agricultural Hall, with the grounds and adjoining property. The property is valued by the claimant's witnesses at sums varying from 141,774l. to 154,810l., and by the Canal Company's witnesses at sums varying from 43,866l. to 49,680l. The compensation awarded by the arbitrator is 70,352l.

THE "Congregational Year Book" for 1889 states that on December 15 there were in England and Wales 4,542 Congregational churches and mission stations, affording accommodation for 1,630,000 persons. In Scotland there are 101 churches; in the Channel Islands, 11; in Ireland, 23, with 95 evangelistic churches; and in the British colonies, 717.

MR. J. C. HALLIDAY, gas-lighting and ventilating engineer, and the inventor and maker of the "Clapton" light, has left London for 12 Grainger Street, Newcastle-on-Tyne. In the interest of the gas-consuming public, it may be noted that the saving in gas bills where the "Clapton" light is in use is computed for the year 1888 at no less a figure than 31,437l. 10s., and that the total saving effected since its invention by use of the "Clapton" light amounts to 100,000l. Mr. Charles Bell,

of Dashwood House, a well-known architect, was so pleased with the illumination when he saw it first used, that he has adopted it since in buildings erected by him, as giving the best illumination by gas with the fewest number of burners.

MR. E. H. SHORLAND, of Manchester and London, has just supplied his patent Manchester stoves to warm and ventilate the new ward of the Grantham Hospital. The architect is Mr. R. Adolphus Came, of London.

DURING the past twelve months the Wigan Coal and Iron Company (Limited), who employ 10,000 workmen at their extensive collieries in the district, have been engaged laying down extensive new steel works at Kirkless, the headquarters of the company. Previously, the company turned out a large quantity of wrought-iron, but the demand for that quality of the metal has of recent years fallen to a great extent, and steel has been utilised in its stead. It is estimated that 50,000 tons of steel blooms are consumed in Lancashire every year, and it is with the view of supplying this that the company decided to lay down new plant. This consists chiefly of four 15-ton melting furnaces, each capable of producing from 180 to 200 tons of steel per week, and it is estimated that the works will give employment to several hundred men. Operations have commenced at the works, which are illuminated by electric light.

MESSRS. JAS. DONALD & SON, ironfounders, Johnstone, have just delivered the first of four heavy castings, the total weight of which amounts to between 80 and 90 tons. The castings are for plate-shearing machines, and each "cheek" weighs upward of 20 tons. The work is for Messrs. Robert Harvey & Co., Parkgrove Ironworks, Glasgow. The machine when completed will cut 1½-inch steel-plates with a clip of 10 feet at a time.

AN award has been issued by Mr. Beadel, in the arbitration which recently took place between Mr. Richard C. Naylor, of Hooton Hall, and the Manchester Ship Canal Company, as to the compensation to be paid to Mr. Naylor in respect to about 121 acres required for the Ship Canal undertaking, and for the consequential damage to Hooton Hall and the adjoining estate. There was a further claim for certain foreshore rights, the existence of which were partly disputed by the Canal Company. The arbitrator awards in respect to the land taken and consequential damage the sum of 28,925l., and a further sum of 1,834l. if the right to the disputed foreshore can be sustained. For the foreshore about which there was no dispute the arbi-

trator awards 2,578/. In the evidence before the arbitrator the lowest sum placed on the value of this property by the claimant was 82,811/., of which 4,251/., was in respect of the disputed foreshore.

#### REMOVING GRANITE RUST.

M. DETAIN sends to *La Semaine des Constructeurs* one of his sensible letters on granite, or rather on causes of discoloration of granite by rust, and the methods of preventing and removing this discoloration. In most granite countries a certain amount of iron is scattered through the rocks beneath the surface of the earth, usually in form of sulphide, crystallised in the well-known cubical, gold-coloured particles of iron pyrites. The crystals of pyrites occur in many other rocks besides granite, more particularly, perhaps, in slate and coal, and are frequently supposed to be gold. Wherever they occur, they decompose on exposure to the weather, leaving ultimately a free oxide of iron, which is washed by rain over the surface of the stone. Many white or mottled marbles also contain iron, which slowly imparts to the surface, under the action of the weather, a warm burnt-sienna colour. This is not a serious disadvantage to marble, but in granite the iron stain combines disagreeably with the natural colour of the stone, and granites containing iron particles should be rejected. According to M. Detain, the French granites of a dark grey colour are rarely, if ever, affected by rust. Those with white ground are more apt to contain iron, but are tolerably safe; while those with pink or red ground are almost sure to rust. With us, red granites are no more subject to rust stains than others. There are some red granites which contain iron, but there is at least an equal number of grey and white stones with iron particles in them, and as these soon assume an unpleasant appearance on exposure, new granites should be tested. The best test, and one which cannot be too strongly recommended to architects who have occasion to try a new stone, consists in a visit to the quarry, where its merits and defects may, with a little care, be ascertained with certainty; but washing the suspected stone with muriatic acid, and allowing the acid to dry on, will often bring out the colour of iron. Singularly enough, the same means answers for removing the rust stains which have already formed on a stone. The muriatic acid readily dissolves the rust, and if it is then washed off with plenty of clear water, the

stain will disappear until the atmospheric influences have produced a new coat.

#### BUILDING MATERIALS IN AMERICA.

WHILE our lumber districts are being rapidly depleted, says the *Architectural Era*, not only by the increasing demand for lumber, but also by means of the destructive forest fires which occur with such alarming frequency, it is a source of consolation to reflect that we shall not lack for building material as long as the earth remains. The vast resources of America's stone quarries may be said to have only just begun to be developed. There is probably no computing the value and extent of the wealth which still lies undiscovered in the earth in the form of granite, sandstone, marble, and perhaps some new and more beautiful building stone than any now known. There are probably few localities in this country which do not possess somewhere in their vicinity some kind of stone suitable for building purposes. While we deeply regret the increasing scarcity of lumber, and should be very sorry to see the predicted lumber famine realised, yet we should rejoice to see stone more largely used in the structures of the day. No material is so appropriate for churches, none so lends itself to the expression of that calm dignity and majestic repose required in ecclesiastical architecture, as grand and enduring stone. A more general use of stone as a building material would soon cause such a decrease in its price as to bring it within reach of the masses. Stone is the most satisfactory and suitable material for the construction of all public and heavy buildings.

#### STONE-CUTTING BY WIRE ROPE.

SOME months ago we made mention, says *Stone*, of a foreign device for cutting stone by means of steel bands or wire rope made to run around pulleys like a band-saw. Since that time we have been investigating the matter more fully, and are now in possession of full detail drawings and specifications of all that pertains to the apparatus. As soon as translations can be made from matter in hand and cuts prepared, we will give all information extant upon this subject. Primarily, it is well to say that the results contemplated are much more extensive than was suggested in the original articles published by us. Not only stone-cutting but stone-quarrying in all its

**CHARLTON, LONDON. S.E.**

branches, where cutting is of use, is contemplated. It is intended for horizontal, vertical, or angular cutting. By cutting a channel through the bed of a quarry, horizontal cuttings of any length may be made, subsequent to which the machine may be adjusted for vertical cutting. These may be regulated to any angle. In such cases it is entirely possible to cut vertically any direction into the rock and then horizontally and, if desired, through to the top again. While it might not be necessary to do such work at any time, the somewhat fantastic illustrations show us quarry with a central source of power and cords running in all directions, some of which are making vertical, others horizontal cuttings; again, others which are transmitting power for the purpose of elevating and conveying stone blocks. Again, there are those which are cutting the quarries into various finished forms. All of the details appear to have been worked out in a thorough and practical way. The means of transmission of power when under cover is by hemp rope, otherwise wire rope. The details of the carriers and tighteners are worked out in the most complete manner. Hemp rope as a means of transmitting power under cover is now coming very generally into use in this country, and has long since been very generally employed in other sections. One of the interesting illustrations of the use of wire rope in cutting is the gangs where large blocks are cut into many parts. The details, while most carefully worked out, are of the simplest character. In the cutting from the quarry the waste is only about one-half of one per cent., and as by its use it is possible to almost entirely do away with blasting or drilling, the general saving is apparent. It is said that the work accomplished is fifteen times greater than possible by old methods.

#### THE BLUE-BRICK TRADE.

ON Thursday in last week a meeting of the blue-brick makers of South Staffordshire, Warwickshire, and Worcestershire was held at Birmingham. Mr. Putress presided; and among the firms represented were the Haunchwood Brick Company (Nuneaton), Hathern Brick Company (Loughborough), H. Doulton & Co. (Rowley), Wood & Ivery, Limited (West Bromwich), Ketley Brick Company (Kingswinford), Barrows & Barrows (Great Bridge), Hockley Hall Brick Company, Limited (Tamworth), Roberts & Cooper (Brierley Hill), Stanley Brothers (Nuneaton), W. Morris (Oldbury), Partridge & Guest (Rowley), J. W. Howlett (Oldbury), Cakemore Brick Company (Rowley),

S. J. Sadler (Oldbury), P. and S. Wood (Tipton), J. Whitehouse. Mr. Webster (Messrs. Wood & Ivery) was appointed hon. sec.

The Chairman said that a circular had been sent out to all the blue-brick makers. Although they had in previous years held similar meetings to the one now summoned, and nothing satisfactory had resulted, that was no reason why the present one should not lead to something beneficial. He thought they were all agreed that prices were too low.

Mr. Rogers (Messrs. Stanley Brothers) said he thought the present time was a good one for advancing prices. In the Warwickshire district the price of fuel had increased 25 per cent., and consequently makers could not afford to sell at the old prices. There was a movement apparent for a general advance of prices.

Mr. Aglow (S. J. Sadler) said his firm was quite anxious for an advance to take place, but their experience of those meetings in the past had been that, after it had been decided to advance prices, they found some of their neighbours underselling them. Consequently they did not feel inclined to take any decided action at present, but would heartily co-operate with the general body of makers in securing an advance.

Mr. Hodson (Loughborough) said his opinion was that their trade had been damaged by the middlemen, who had effected the decrease in prices. The question he asked was whether any of them were making a profit after receiving 5 per cent. for the money invested in their works? He was quite sure blue bricks ought to go up. He thought if the blue-brick makers would strike it would have the effect of sending up prices. The time had come when prices would have to be increased, but such increase could only be maintained by the whole of the brickmakers standing together.

Mr. Webster said that as soon as the price of slack went up his firm issued a circular stating that the price of bricks would have to be increased. They received replies to that circular from the merchants stating that they were the only people in the trade who had increased prices. If the brickmakers would remain firm he thought there would be no difficulty in maintaining prices.

Mr. Hamblett said his firm had announced a rise, but it was no use doing it unless all the makers did it.

Mr. J. W. Howlett supported the proposition for an advance.

The Chairman suggested that they might make an advance of 10 per cent. on best bricks, 20 per cent. on odd-side stuff, and 5 per cent. on common bricks.

After some further discussion, on the motion of the Chair-

MANY THOUSANDS IN USE.  
SUCCESS GUARANTEED.

By using the Patent Syphon-Pipes the Heating Power of the MANCHESTER GRATE is increased, and the whole arrangement rendered simplicity itself.

The MANCHESTER GRATE combines great Radiating Power with Economy, and will burn Coke or any kind of fuel.

It delivers volumes of Pure Warm Air into the room in which it is fixed, and also into rooms above or adjoining, maintaining an equable and agreeable temperature throughout.

New Illustrated Catalogue Free on Application.

man, seconded by Mr. Whitehouse, the following resolution was passed:—"That this meeting, comprising the principal blue-brick makers of South Staffordshire, Warwickshire, and Worcestershire, hereby unanimously agree to advance the price of blue bricks 10 per cent, such advance being entirely due to the increase in the price of fuel and other material."

An amendment proposing to refer the question to a committee to draw up a minimum list of prices was rejected.

Mr. Hodson proposed a resolution to the effect that all the manufacturers should circularise their customers of the advance, and the circular should be signed by the hon. secretary. Mr. Smart seconded the motion, which was carried.

A vote of thanks to the chairman terminated the meeting.

#### THE FORTH BRIDGE.

NOTWITHSTANDING the frequent stoppage of labour in consequence of stormy weather, rapid progress has been made recently at the Forth Bridge; indeed, so materially has the work been advanced that the gigantic structure is now assuming a shape which indicates that the bridge is within measurable distance of completion. The great centre gaps which require to be spanned are every day being reduced in length, and to the non-engineering eye this part of the works now presents less difficulty of accomplishment than it may have done a few months ago. Never anticipating any serious obstacle in the building of the spans, the engineers are finding this section of the work more simple than many of the previous stages. Both on the Queensferry and Fife sides bay No. 3 has been completed, and No. 4 commenced too. As has been the case throughout, the work on Inchgarvie is behind that on either side. At the sound end of the island, however, the third bay is pretty well advanced, while another month will bring the north side as far forward. Some idea of the limited extent of work yet to be undertaken may be gathered from the fact that during the months of August, September, and October material was erected on the three piers at the rate of 2,000 tons per month, and that only 9,000 tons are now required to finish the work. From this it is calculated that should the weather not interfere, and the workshops at Queensferry be able to cope with the demands made upon them, the bridge proper may be completed by the beginning of May next. In the sheds on the south side, night and day shifts are being constantly employed, but only one staff of men is found necessary on the erections.

The 30th October is the date fixed for the entire completion of the bridge, and it is confidently expected that everything will be in readiness by that time. While the bridge is in this forward condition, the approach railways on each side are also being pushed rapidly forward, large staffs of men being employed by the contractors. The most serious engineering difficulty, perhaps, which has been encountered in connection with the railways is between North Queensferry and Inverkeithing, in consequence of the great masses of rock which exist there. At one point the cutting required is so deep that it has been resolved to construct a tunnel.

#### THE HAMILTON IRONWORKS, GARSTON.

AMONGST the oldest-established firms in the country engaged in the manufacture of iron roofs, buildings, and constructional wrought and cast ironwork, together with various specialities in galvanised and corrugated iron, iron fencing, gates, and ornamental railing, is the firm of Messrs. Francis Morton & Co., Limited, of Liverpool. The gradual extension of their business has necessitated constant enlargement of premises, and they have added to their Liverpool establishment extensive works situated on the Mersey, at Garston, a suburb of Liverpool. These works cover more than 10 acres, and comprise an extensive range of lofty, well-lighted buildings, with private dock and railway siding accommodation. The north side of the enclosure is occupied by a shop, 600 feet long by 120 feet wide, for girder, bridge, and roof-building purposes, which contains a long range of smiths' hearths and a very complete plant of tools, embracing the latest improvements in punching machines, steam hammers, rivetters, bending rolls of various power, planing machines, &c., a special feature being multiple punching machines, one of which will at one stroke punch forty-eight holes through a plate  $\frac{1}{4}$  inch thick, the number of punches in use being regulated by the requirements of the work. Another machine will punch a multiple of holes from  $2\frac{1}{2}$ -inch pitch, and can be regulated to any pitch used in general work. The shop is traversed throughout its length by railway lines, and fourteen overhead gantries and cranes contribute to the convenience of erecting under cover a large extent of work. Adjoining this shop is one for tinmen's use, and a double-storey building used for templates and as setting-out floors, next to which come the drawing and general offices. On the opposite or south side of the spacious open yard is a series of shops fitted with plant for various classes of work, viz., the foundry,

# "EMPRESS"

# SMOKE

EWART & SON,  
346 EUSTON ROAD,  
LONDON, N.W.

# CURE.

200 feet by 120 feet, with two cupolas inside the building and two outside. Here again are overhead travelling cranes, extending the whole width of the shop, with the usual arrangement of core-drying stoves, loam mills, and a dressing shop for finishing up the castings. In this foundry single castings up to forty tons weight can be turned out, and it is sufficiently commodious to allow of the metal being left to cool in the sand for a much longer period than is usual in the ordinary way, an advantage in securing good castings that has to be frequently sacrificed in the crowded-up foundries attached to some establishments. Adjoining is a brass foundry, and subsequently a fitting and turning shop, 200 feet by 120 feet; a smiths' forge, a building 200 feet long, containing fifteen fires; saw-mill and painters' shop, a two-storey building, 155 feet by 40 feet, the upper part of which forms a pattern shop, the basement being set apart for wood-working machinery; two large establishments filled with machinery for the manufacture of patent iron telegraph poles; corrugating machinery shop, 155 feet by 80 feet; packing shop, 65 feet by 80 feet; and, on the east side, general stores and stabling for thirteen horses, which latter, however, are not needed, the firm having their own locomotive for haulage purposes, rails being laid on a complete system to each shop. The west side has a frontage of about 500 feet to the Mersey, being entered from that river by a private dock, which runs up into the open yard, and provides accommodation for vessels up to 270 feet in length. The dock is fitted with steam travelling crane for loading and discharging material. The motive power for driving the various machinery in the works consists of two 50 horse-power engines, a 16 horse-power gas engine, and considerable hydraulic power. The fresh water supply is derived from a covered reservoir in the yard, holding 160,000 gallons, distributed through the works by hydraulic ram. The London offices are at 9 Victoria Chambers, Westminster.

#### THE ASSOCIATED CARPENTERS AND JOINERS.

THE twenty-seventh annual report of the Associated Carpenters and Joiners, after referring to the trade disputes during the year, alludes to the improvement in trade, regarding which their expectations had been more than realised. The income for the year amounts to 6,155*l.* 6*s.* 6½*d.*, or an increase of 214*l.* 13*s.* 8*d.* over the income of the previous year. The gross expenditure for the year amounts to 6,324*l.* 15*s.* 0½*d.*, or a loss

of 169*l.* 8*s.* 6*d.* on the year's transactions, thereby reducing the funds on hand to 8,169*l.* 18*s.* 2*d.*, which, on a membership of 3,833, makes the Association worth 2*l.* 2*s.* 7½*d.* per member, or 4½*d.* less per member than last year. Of this sum 5,231*l.* 2*s.* 4½*d.* belongs to the trade fund, 2,660*l.* 6*s.* 9½*d.* to the sick, and 278*l.* 9*s.* to the idle fund, being a gain of 31*l.* 17*s.* 7*d.* to the trade, a loss of 388*l.* 1*s.* to the sick, and a gain of 186*l.* 14*s.* 11*d.* to the idle fund. The return of plant held by the Association, exclusive of books, &c., is estimated at 309*l.* 6*s.* 8½*d.*, making the total worth of the Association 8,479*l.* 4*s.* 10½*d.* The general secretary says:—Fortunately for us, although the amount paid on account of trade disputes is largely in excess of the sum which we have expended under this head during the past few years, there is little room for complaint on the part of our outside critics, since by far the largest amount of this sum has been spent not for the purpose of forcing wages up, but in preventing a few grasping employers from forcing them down in the face of a rising market.

#### THE PARIS EXHIBITION OF 1889.

AN influential and representative committee was formed a few months since in London, under the presidency of Lord Brassey, in order to assist the French authorities with their work, and to form a loan collection worthy of this country, which has played so important a part in the history of the means of transport, and which should supplement and complete the French exhibits of the same nature. This committee is affiliated to the French committee of organisation, and has for its vice-presidents Mr. T. Sutherland, M.P., and Mr. G. Findlay, manager of the London and North-Western Railway. It includes two sub-committees, the first dealing with means of transport by land, of which Mr. H. Oakley, manager of the Great Northern Railway, is chairman; the other taking charge of the means of transport by water, under the chairmanship of Mr. B. Martell, chief surveyor at Lloyd's Registry of Shipping. The work already carried out by these committees has assured a loan collection larger and more complete of its kind than has ever before been brought together. Among the great attractions which the Paris Exhibition of next year will offer, one of the principal will be the palace of the Liberal Arts. This building will be similar in design to the Fine Arts Palace, and will be chiefly devoted to the display of objects that will illustrate the development of artistic and commercial industries from the

# FIRE! FIRE! FIRE!

## GRIFFITHS' "PYRODENE" FIREPROOFING LIQUID

(NON-POISONOUS).

### Transparent Liquid for Rendering Woodwork Uninflammable,

Without altering its appearance, and where Painting is not desired, such as Wooden Fittings in Exhibitions, Churches, Pews, Matchboarding, Theatre Scenes, Wooden Stairs, Joists, Beams, Floors, Factories, Stables, Mills, &c., in fact, Structures of an inflammable nature of all descriptions. Acts as a priming for new Woodwork for Paint or Varnish. Also for rendering Theatrical and Ball Dresses, Curtains, Paper, Felt, Canvas, &c., perfectly uninflammable.

Griffiths' Liquid penetrates the pores of the wood. It lasts as long as the wood itself. It prevents Dry Rot and decay in house timbers. It does not crack, peel, or rub off.

It is perfectly innocuous and free from smell. It will keep any length of time. Any one can apply it. One gallon will cover double that of any other priming.

AND

All Woodwork in new houses should be fireproofed with this Liquid, the cost is so trifling in comparison with the preservation of the timber and freedom from risk of fire. If work is desired to be painted afterwards, Griffiths' Pyrodene Paint is best for the purpose.

## GRIFFITHS' "PYRODENE" FIREPROOF PAINT.

READY FOR USE. NON-POISONOUS. ALL COLOURS.

This Paint is manufactured for preservative and decorative purposes equally as for its FIRE-RESISTING qualities. The Fireproof Paint and Fireproofing Liquid is used at some of the principal Theatres in the United Kingdom.

#### RECENT TESTIMONIALS.

From Messrs. MAXWELL & TUKE, Architects, 29 Princess Street, Manchester: December 28, 1887.

DEAR SIRS.—We used your Paints in nearly the whole of the works for the Royal Jubilee Exhibition, and with very satisfactory results.

Yours truly, MAXWELL & TUKE.

To Messrs. Griffiths Bros. & Co., Dashwood House, London, E.C.

From S. C. LOWE & SON, House Decorators, 32 Cavendish Street, Stretford Road, All Saints, Manchester: November 22, 1887.

DEAR SIRS.—In reply to your inquiry, we, as one of the contractors for the painting Manchester Jubilee Exhibition, which closed on the 10th of this month, have pleasure in stating that both your "Aqual" Paint, and also your "Pyrodene" Fireproof Paint, have given great satisfaction. We found them work easily with a covering power of from 30 to 40 per cent. over ordinary paint. Although applied during intense frost, and having been subjected to an almost tropical summer, followed by the drenching rains of this autumn, they are as fresh in colour and have as firm a grip as when applied, and appear quite unaffected by the nine months' exposure. We consider them, therefore, well adapted for all work in any climate.—Yours truly, S. C. LOWE & SON.

To Messrs. Griffiths Bros. & Co., London.

CHEAPER AND MORE DURABLE THAN ORDINARY PAINT.

GRIFFITHS' "PYRODENE" FIREPROOFING COMPANY, Limited,  
4 & 5 DASHWOOD HOUSE, NEW BROAD STREET, E.C., LONDON.

earliest times to 1878, the date of the last International Exhibition held in Paris. The most important section of this display will be an exhibition of the means of transport by land and water. The growth and development of railways, transport upon common roads, internal navigation by rivers and canals, everything connected with shipping, even the art of aerostation, will come within the limits of its comprehensive title. As regards the last-named subject, the great dome which forms the central feature of the Liberal Arts Palace will be devoted to the display of balloons and their accessories.

#### PERUVIAN RAILWAYS.

At the last meeting of the Civil and Mechanical Engineers' Society, a paper was read on the Oroya Railway, Peru, by Mr. W. Alfred Eckersley. The author, in commencing, chiefly alluded to recent Peruvian history, and the way in which, during unnatural inflation, money was borrowed in the most reckless manner for railways and other public works which were only half executed, when such a series of national reverses and disasters ensued as to almost paralyse the commerce and trade of the country. The natural resources of Peru, however, are so great that the author expressed the greatest confidence in the future prosperity of that country. Proceeding to describe the railway, he stated that the line was now open to Chichas, a distance of 87 miles from Callao, but until completed to Oroya, a further distance of 50 miles, the object of the line and development of the rich mineral and productive districts of the interior would not be accomplished. The present terminus is over 12,000 feet above sea-level, and is gained by an uninterrupted series of ascending gradients, the steepest being 1 in 25. The sharpest curve allowed is 6 chains radius, but in several places single and double back shunts have been found necessary. The river Rimac and numerous gorges are crossed by viaducts of the American pin-truss description, the spans varying from 91 to 205 feet, and resting upon lofty but spidery-looking iron piers, sometimes over 250 feet high, and the author seemed much impressed with the suitability of this description of ironwork for such work, and considered it far superior to rivetted structures. In making the surveys for the line, and also in constructing the viaducts, men and materials were slung along ropes across the lofty chasm, and much courage and energy must have been displayed, one of the largest of these

grand examples of engineering skill having been erected in four months. The author tested the viaducts with heavy rolling and stationary loads, and found them to be very satisfactory, the deflection at centre being generally less than 1 in 2,000 and the recovery perfect.

#### PROPOSED HARBOUR FOR DEAL.

A MEMORIAL was forwarded by the Deal Town Council on Monday to the Board of Trade in support of a proposal to construct a harbour at Deal. The memorial shows that Deal is without any harbour or shelter for ships or boats; that for generations a large part of the population has been engaged in nautical pursuits, but from the want of a harbour they were unable to engage in deep-sea fishing, and at certain times of wind and tide were unable to carry on their occupation at all as they could not launch from the beach; that through the decline of their occupation the race of Deal boatmen was likely to die out unless some steps were taken; that the harbour would open up import and export trade as well as deep-sea fishing, afford further communication with the Continent, and provide a safe refuge, and be of the greatest use from its position in connection with H.M. Navy, especially in the time of war, as a rendezvous for small cruisers, and as a coaling station and victualling depôt.

#### DURABLE MATERIAL FOR DAMP-COURSES.

A CASE was lately heard at Stratford before Mr. W. W. Glenny and Mr. B. Tabreim relative to material to be used for damp-courses, and which is of interest as bearing on the by-laws of Local Boards. Many professional men and builders were present at the hearing. Mr. John Jolliffe, builder, of Wanstead, was summoned by Mr. J. T. Bressey, surveyor to the Wanstead Local Board, for erecting a building in High Street, the wall thereof being without a proper damp-course of sheet-lead, asphalt, or slates laid in cement, or other durable material impervious to moisture, contrary to the by-laws of the Board.

Mr. W. Blewitt, clerk to the Local Board, said that the proceedings were instituted under the 15th by-law of the Wanstead Local Board, which provided that all damp-courses used in the erection of houses should be made of sheet-lead, asphalt, or slates laid in cement, or some other durable material impervious to moisture; and the point in this case was

whether a substance proposed to be used by the defendant was a material calculated to be a proper damp-course. The by-law said "or other durable material impervious to moisture," and it must be quite obvious that a material might be used composed of either sheet-lead, asphalte, or slates laid in cement, impervious to damp, but at the same time not durable. The lead or the asphalte might be laid so thin that, though impervious, it would not be durable. The word durable by itself was meaningless; it should be read in this case with the context; and he would submit that if a material was used for damp-course which would not last as long as the substance in which it was placed, then that material would not be durable. The defendant knew that the Local Board had an objection to the material he proposed to use in this case, because he had before attempted to use a substitute to the material passed by the surveyor; nor had he forced on these proceedings in his own interest or in the interests of builders; it was certainly done on purpose for a test case, and was fought out for him by an enthusiastic supporter of the material.

Mr. Hume-Williams, who represented Mr. Jolliffe, said that was admitted, but it would not in the least affect the real question before the Court. He appeared there on behalf of Messrs. D. Anderson & Co, of 812 Old Ford Road, who manufactured this substance to the extent of several thousand feet a day. It was used all over the kingdom, and this was the first time that its efficacy and durability for the purposes of damp-courses had ever been called in question.

Mr. Bressey, the surveyor to the Wanstead Local Board, said he had held that position for twenty-two years, and since the model by-laws came into force in 1882, none of the substance proposed to be used by the defendant had been used in his district. The substance in question was impervious to damp, but was not in his opinion durable.

In answer to Mr. Hume-Williams, he said there had been considerable correspondence between him and Mr. Seckham Witherington, architect, with reference to this substance, which he (Mr. Witherington) specified for damp-courses. On March 8, 1888, he had a sample of it sent to him. It was proposed to use it for some houses then being built by Mr. Jolliffe, but those houses were completed with slates. He did not know if the slates were only used in that case, because there was a specific time fixed for the completion of the houses. In the next building this particular article, he understood, was put in in order to raise the point as to its durability. He did not analyse the sample which was sent to him, but he "put it before the fire

and smelt it." It was impervious to damp; he only objected that it was not durable. He had never tried Anderson's Asphaltic Felt. Within his experience walls with a damp-course did occasionally subside; they were liable to a slight settlement. In his district slates were used for damp-courses, two layers of slate in cement. There was first a layer of cement, then slates, a layer of cement, then slates, and another layer of cement, sandwiched in fact. If a wall subsided, the slates would crack at that particular place. Anderson's substance was pliable. Several kinds of asphalted felt were used. In his district about thirty houses a year were built, and in every case the damp-course used had to be approved by him. If different sorts of damp-course were used he would be caused some trouble. That, however, was not the reason for his objection to this stuff; his objection was because it was not durable. In its composition there was tar or pitch, and certainly heat would not improve it. He was desirous of keeping this asphalted felt out of his district, and if he succeeded it would save him a great deal of trouble.

Being re-examined by Mr. Blewitt, Mr. Bressey continued:— If a building in part subsided, any damp-course would break. It would, as he had said, save him trouble to keep this asphalted felt out of the district, and it would also save the occupiers of houses trouble, because with its use the house would set damp. He would not allow the use of this asphaltic felt because he tried a similar substance years ago and it failed. It was not possible to supply any test as to its durability. It would yield to pressure and would probably get half as thick.

Mr. Hume-Williams then read the correspondence on the subject of the use of Anderson's Asphaltic Felt with Mr. Blewitt, Mr. Witherington, and the Local Government Board, and dwelt at great length on the merits of the felt and the demerits of slate damp-courses. In the latter case the slates would crack, and so also in some cases would the cement, if there happened to be a small stone or pebble in the cement; and in a case of that sort the damp-course was not impervious to damp, nor was it durable. Dealing with the rough test of placing the asphaltic felt before the fire and smelling it, adopted by Mr. Bressey, Mr. Hume-Williams said that it was an insult to the Court to come and adduce that test as a scientific one; the case was really a test one, and he would point out, and desired to impress on the Bench, that the onus laid upon his friend Mr. Blewitt, who had to prove that the asphaltic felt was not a proper damp-course, but he had not taken the least trouble to support by independent testimony or scientific evidence the

individual opinion of his surveyor. It was a matter of vital importance to Messrs. Anderson & Co., for it would be idle to shut their eyes to the fact that if that prosecution succeeded, their reputation and the sale of this asphaltic felt was doomed.

Professor A. H. Allen, F.I.C., F.C.S., president of the Society of Public Analysts, consulting and analytical chemist, of 101 Leadenhall Street, E.C., and 67 Surrey Street, Sheffield, deposed that he had carefully analysed a sample of Anderson's Asphaltic Felt, and from the result of experiments he came to the conclusion that it was undoubtedly impervious to damp. [Mr. Blewitt intimated that its imperviousness to moisture was not disputed.] As to its durability he could only speak by analogy—that he had not lived long enough to be able to testify as to how long it would last. It was principally composed of pitch, and the Egyptian mummies were preserved in pitch. In this asphaltic felt there was 54 per cent. of coal tar oil, 28 per cent. of fibre, and 18 per cent. of sand. Each grain of sand was unalterably durable, but he would only treat the sand used here as an accessory. Practically there was two-thirds of pitch to one-third of fibre, and in use the fibre prevented that spreading of the pitch suggested. [A section of a wall, which Mr. Hume-Williams said had been immersed in a tank of water for eighteen months, was brought into the Court.] The felt used as damp-course in that section of a wall was asphaltic felt. The mortar used had a quantity of lime in it, but the lime does not injure the felt. Lime had a deleterious effect on lead; in fact, leaden pipes laid in mortar were found to be much depreciated.

In answer to Mr. Blewitt he said his opinion of this as a damp-course was formed by experiments with the constituent materials, not by experience of its use. Assuming that a damp-course of slates and a damp-course of this felt were used on the same wall, he would say both yes and no to the question whether one was as good as the other—there were atmospheric influences. For roofing purposes the felt would be less durable than slates. A double course of slates would be as good as the felt, but there was the possibility of the slates cracking. The pitch used for the Egyptian mummies was not an artificial pitch; it was a natural asphalt. "Watts's Dictionary of Chemistry" was an admirable compilation, but its definition of asphalt did not fit in with this asphaltic felt. That referred to natural asphalt; in commerce coal tar was used in asphalt.

Asked by Mr. Hume-Williams, he said he regarded asphaltic felt as both impervious and durable, and suitable for damp-courses.

Mr. W. Seckham Witherington said that he specified this asphaltic felt to be used in the building in question as the best to use for damp-courses. In his experience of thirty years he thought it was a material that would make a proper damp-course, and that it was a material impervious to moisture and durable. Its component parts, its flexibility, its application, its economy recommended it, and it would not break in a settlement in the building—it was plastic.

Questioned by Mr. Blewitt, Mr. Witherington said his experience of the felt extended over nine months. He had used another felt, but on receiving a sample of this at once saw its advantages. He would use this felt for one reason—because of the possibility of settlement. Last year work passed through his office to the extent of 120,000/ to 130,000/, and perhaps he had had some settlements; they could not be guaranteed against. Infinitely he preferred this asphaltic felt to lead. It would certainly be better laid in cement, but he would not put his clients to the expense of using cement. The asphaltic felt would be perfectly adequate in mortar alone.

Mr. Thomas Stone, architect, of Great Winchester Street, said that from his experience of thirty-five years he now always specified asphaltic felt, because he thought it durable and impervious to damp. Some slates he could put his fingers through. His experience of the felt only extended over a few months. He preferred the felt to asphalt.

William Gregar, builder, of Stratford, said that he had used tens of thousands of feet of the material. He had used it in public buildings in the parish. It was a durable material and impervious to damp.

In answer to Mr. Blewitt he stated he had used material of the sort twelve years ago, but his experience of Messrs. Anderson's felt was but of nine months.

Mr. Hume-Williams was about to call other witnesses, but was stopped by the Bench, and Mr. W. W. Glenny, the chair man, said:—After hearing the evidence put before us, we must dismiss the case.

Mr. Hume-Williams asked for costs, but the Chairman said the Bench thought the Local Board had acted in perfectly good faith and would not give costs.

This decision, the only one possible to be arrived at, when brought to the test of judgment, will be of much benefit to the building trade, as it will protect honourable contractors and manufacturers from annoyance through arbitrary interference of local bodies, which, however well intentioned, too often results in petty despotism.

## BEAN'S PATENT DIRECT-ACTING VALVELESS WASTE-PREVENTING CISTERNS.

These Waste-Preventers are simple in construction and rapid and powerful in action. The working parts have been improved and are well balanced. The arrangements for charging the siphon are such that a slight pull by hand is all that is necessary to cause the immediate and automatic discharge of the contents of the Cistern.

THE CHIEF ADVANTAGES are—(1) the direct-acting method of charging the siphon, by which the full flush is obtained at once; (2) simplicity of construction; (3) no valve in the bottom of the cistern to cause leakage; (4) no tight-fitting parts to corrode or get out of order; (5) no waste incurred by fastening the "pull"; (6) insures a rapid and regulated flush without holding down the pull.

**BUILDERS' TECHNICAL AID INSTITUTE.**

IN view of the many technical difficulties that surround the trade of the builder, it has been decided by a few professional gentlemen to organise and develop an institute whereby, with a system of co-operation, builders may gain many advantages from interchange of opinion and unity of interest. The objects are to found an institute for the technical assistance of builders, by which they may be able to obtain not only practical advice, but also efficient assistance in every branch of work appertaining to a builder's office. It is proposed to give members the benefit of a central London address where letters can be received, and calls in town and business interviews arranged, a subscribers' general room being set apart for that purpose, and provided with books of reference, directories, and building periodicals, and where information and the best professional advice regarding the various building technicalities and problems will be given for one year from date of entry.

**WESLEYAN CHAPEL AND SCHOOL EXTENSION.**

SITES have been secured in Woodhouse Lane and Roundhay Road, Leeds, for the erection of Wesleyan chapels, and it has been decided to commence operations as soon as possible, and that buildings should be erected at a cost of about 12,000/. On the Woodhouse Lane site it is intended to build a chapel to seat upwards of 900 persons. Schools will eventually be added. In Roundhay Road the schoolrooms will be built first, but, until the chapel is added, they will also be used for worship. The schools at each place will accommodate some 500 children. Seats will be provided for about 750 persons in the Roundhay Road chapel.

**PATENT RAISING GEAR FOR PENDULUM HYDRO-EXTRACTOR.**

AN important improvement in hydro-extractors or centrifugal machines has been patented by Messrs. Alliott & Haughton, and is manufactured by Messrs. Manlove, Alliott & Co., Limited, Nottingham, the well-known makers of steam laundry machinery. This improvement relates especially to that class of hydro-extractor or centrifugal which has an engine attached underneath the machine, and is suspended upon rods. It has

been usual to construct a pit under such machines for the purpose of getting underneath them to examine the engine, and in cases where the floor has been constructed of fireproof material, or for other reasons it has been impossible or inconvenient to make a pit to obtain access to the under side of the machine, it has been necessary to turn it over on its side for examination. Both these methods have been found to be inconvenient, and this improvement is designed to get over these difficulties. By a simple modification of the suspending arrangements, the machine can be rapidly lifted to a sufficient height to allow any one to get underneath it to examine the working parts. The engraving shows the machine raised up for this purpose, the dotted lines indicating the ordinary working parts.

The machine is thus seen suspended on rods, and with self-contained engine. It has been adopted in many places where

it would have been difficult to employ any other type of machine. The fact that it requires practically no foundation, may be set down almost anywhere, even on upper floors, and requires only a steam-pipe to connect to it, makes it an extremely convenient type in many instances. It will be seen that with a machine of this type the working parts of the engine are below the pan, and that it has consequently been necessary always to make a small pit, or to cut a hole in the floor to enable a workman to get below to conveniently examine the engine and moving parts. In a few cases where the floor has been constructed of fireproof material, or where for other reasons it has been impossible or inconvenient to make a pit to obtain access to the under side of the machine, it has been necessary, as before said, to turn it over on its side. The workmen do this as seldom as possible, and the engine is consequently run too long a period without examination or adjustment. To get over these difficulties, the arrangement shown in the woodcut has been devised and patented. It will be seen

that the suspension-rods are made with a screw thread along their whole length, and the vibrating joint in the foot of the pan forms a nut fitting the long screw. The upper end of the suspension-rod or screw has a square end which may be turned by a handle or spanner; by this means the machine can at a moment's notice be raised up about 18 inches, or a sufficient height to enable a man to comfortably examine the working parts. Only one spanner is usually supplied with the apparatus, but if required two more can be furnished, so that three men could work all the three screws simultaneously. The device needs no further explanation. It is extremely simple, and will recommend itself to any intending purchaser who cannot conveniently obtain access to the under side of the machine in the ordinary way.

#### MESSRS. LAIRD'S WORKS, BIRKENHEAD.

A NEW boiler shop has recently been erected in Beaufort Road, at the north end of the Great Float, Birkenhead, for Messrs. Laird. This new addition to the large works at present owned by the firm has been constructed in order to meet the changes which have taken place in boiler-making, consequent on the increase of pressure and other causes. It is situated on the land set aside many years ago by the late Mr. John Laird for this or similar purpose, and occupies about 2 acres of ground adjoining the well-known Wirral Foundry of Messrs. G. Bayliff & Son. It is approached from the railway system on the Dock Board's lines by the Beaufort Road siding, by which material is delivered direct on the railway trucks. The shipment of boilers will be effected along the same railway to the large crane on the margin of the West Float, which is now being strengthened to lift weights up to 90 tons. The area covered by the buildings of the new boiler shop is about 6,000 square yards. The building consists of four parallel bays or sheds, so that practically they form one workshop between Beaufort Road and Corporation Road. The main shop for heavy work and for erecting the boilers is in the centre, and is 286 feet long by 63 feet wide. Flanking this on the east side is the shed for receiving the plates and other materials, marking, drilling, and bending them. On the west side of the main shop is the shed for light work, at the south end of which are placed the annealing and other furnaces, with the boiler and engine by which the whole of the extensive machinery and cranes are worked. Still further to

the west and parallel to the other shops is the smithy, having provision for fourteen smiths' hearths, two furnaces, and numerous flanging fires, the blasts for the whole being supplied by means of a large fan driven by steam-power and conveyed thereto by underground pipes. Adjoining the smithy bay are the store-rooms, offices, and moulding loft, all affording ample accommodation. Rails are carried through the works direct from the Beaufort Road siding, whence it is connected with the whole railway system of the country. The machinery at present erected consists of a number of powerful machine tools of the most recent design and construction. The main shop is traversed by two each 50-ton overhead power-driven travelling cranes, of 50 feet span, with 30 feet lift, and one 40-ton power-driven travelling crane. Over the other sheds there are four other travellers to lift from 15 to 20 tons each. In the eastern shed is a very large machine for planing simultaneously the edges and butts of plates up to 28 feet long by 10 feet wide. In the same shed are large vertical plate-bending rolls, which bend plates cold up to 12 feet 2 inches wide, and  $1\frac{1}{2}$  inch thick. Plates have already been bent in these rolls with an area of 170 square feet, and weighing upwards of four tons. There are also two sets of horizontal rolls for smaller work. Under the main central shed is a boiler shell drilling machine for drilling the shells of boilers when put together as complete cylinders, and there is also a boiler back stay drilling and tapping machine moving through 20 feet horizontally and 10 feet vertically. Under the same shed there are two hydraulic rivetters, one of which makes perfect work of rivets  $5\frac{1}{2}$  inches long by  $1\frac{1}{8}$  inch diameter, weighing 3 lbs. each, and has rivetted a large boiler 18 feet 6 inches long by 15 feet 4 inches in forty-eight consecutive hours. The smaller machine has 5 feet 6 inches gap, and works at a pressure of 40 to 50 tons. There are three large, double-ended punching and shearing machines, to punch up to  $1\frac{1}{4}$ -inch holes through  $1\frac{1}{4}$ -inch plates  $23\frac{1}{2}$  inches from the edge, and to shear  $1\frac{1}{4}$ -inch plates  $25\frac{1}{2}$  inches from the edge; also a number of other punching vertical and wall-drilling machines, oval hole-cutting and twist drill grinding machines of various sizes, suitable for boiler-making and other purposes. The smiths' shop is complete with hearths, plate flanging fires, cranes, steam-hammers, and other appliances. The whole premises have a well-arranged system of gas lighting, and the Lucigen and Wells lights have been successfully adopted for the principal shop. The working plans for the sheds were prepared by Messrs. Lewis Hornblower & Sons, under the immediate

## NINTH ARCHITECTURAL AND BUILDING TRADES' EXHIBITION,

Royal Agricultural Hall,  
LONDON, N.,

APRIL 1 to 13, 1889.

Mr. P. SHRAPNEL, the Manager of the highly successful series of Architectural and Building Trades' Exhibitions held at the Agricultural Hall during the last eight years, has much pleasure in announcing that the NINTH EXHIBITION will be opened there on April 1, 1889.

Intending Exhibitors can obtain full particulars on application to—

MR. P. SHRAPNEL,

At his Offices,

20 BUCKLESBURY, LONDON, E.C.

GOLD MEDAL, Inventions Exhibition, 1885.

direction of members of the firm and Mr. Bevis; and the principal contracts for the buildings were carried out by the following contractors:—Brickwork, by Messrs. A. Bleakley & Sons, of Birkenhead; iron columns and girders, by Messrs. Goodwin & Co., Motherwell Foundry, Glasgow; iron roofing, by Messrs. Morton & Co., of Liverpool; Belfast roofing, by Messrs. D. Anderson & Co., of Belfast; painting, by Mr. Wm. Male, of Birkenhead; glazing, by Messrs. Lackland & Co., of Birkenhead; furnaces, by Mr. C. Snape, of Birkenhead.

### ELECTRIC LIGHTING IN LONDON.

ON Friday last two important meetings of electric supply companies for the metropolis were held.

The Earl of Crawford and Balcarres presided at the meeting of the London Electric Supply Corporation (Limited). His lordship stated that they took over the installation at the Grosvenor Gallery in 1887, there being then about 11,000 lamps. The directors of the previous company spent a considerable sum in order to place their dynamos and engines in a very advantageous position; and they contracted with the engineer to supply dynamos sufficient to give the current to 20,000 lights. It was afterwards found, when the two machines were put into position, that the nominal efficiency of 20,000 lights could be safely exceeded, and the present company came into possession of two dynamos capable of giving 30,000 lights. In addition to that there was a system of engines which was very complete, but the engines were not quite sufficient for the large amount of work demanded from them at present. They had purchased a large system of overhead mains—cables for conveying the current from the generating station to the houses of the consumers. A good deal had been said as to overhead mains, but the directors had every confidence in their system, as the best material was used and the work was efficiently done. To satisfy the Board of Trade as to the efficiency of their wires they took one down which had been up for three years and seven months, and after it had been thoroughly tested in the presence of the officials of the Board of Trade, the latter acknowledged that it was in perfect condition. At Deptford they had a dynamo with an engine capable of giving 25,000 lights, and they had every reason to hope that that would eventually be equal to supplying 30,000 lights at least. They had also arranged for another dynamo of 25,000 lights. They would eventually have a capability of 150,000 lights with a

reserve power of 100,000 lights. He thought he might state that they had the whole circuit of London open to them. The only question was how much per mile they were to pay, and he thought they might trust the directors to arrange for that as cheaply as possible. They had applied for provisional orders, which practically embraced more than half of the metropolis. They had asked for powers to deal with the streets in 24 different localities, under the jurisdiction of as many local authorities.

The meeting of the Metropolitan Electric Supply Company (Limited) was held, with Sir John Pender in the chair. He informed the shareholders that the company took over from the Whitehall Company the important works and installation established at Whitehall Avenue. That station, which was of about 10,000 light capacity, was opened on the 1st of October, and the directors had hoped that the full capacity would be taken up in seven or eight months. Instead of that the full lighting capacity had been already taken up. In about two months orders were booked for about 9,000 lamps, and the mains for connecting them were being laid as fast as possible throughout the whole of the Charing Cross district. He had been informed by Mr. Gordon that the guaranteed revenue from the contracts made from the Whitehall works was 13,500*l.* a year. Other contracts were expected to increase that amount by 1,000*l.*, and after allowing for the working expenses and 10 per cent. for depreciation, a profit was expected to remain of 8,500*l.* a year, the capital represented by the Whitehall works being not much more than 40,000*l.* The buildings at Sardinia Street were in hand, and that station would be one of the most important in London. It would embrace the residential property about Bloomsbury, and the shops, newspaper offices, banks, &c., in Holborn, Fleet Street, and east Strand. It would have altogether 50,000 lights, and, as far as they could judge, it would not be long after the installation was completed before it was fully occupied. The machinery for that station had been ordered from the Westinghouse Company, and it would shortly be delivered. That company had put down in America 116 installations, all of which had been successful. They were inviting tenders from English contractors for another installation. He thought they would thus have the benefit of what he might call "contractors' competition." Only ten years ago the electric light was a laboratory experiment, but its use was now becoming almost universal. It was not more than 25 years ago that submarine telegraphy was first introduced, but 40,000,000*l.* was now invested in that enterprise. They, therefore, did not

The "PERFECTUM."

### "PERFECTUM."

In London the above are kept in stock by Messrs. GEORGE WRIGHT & Co., 155 Queen Victoria Street, E.C., who will be pleased to show and explain them to Architects and Contractors.

On view at the Cardiff Exhibition, September and October, and at the Ironmongers and Metal Trades Exhibition, London, November 12 to 24, 1888.

TELEGRAMS—"PERFECTUM," BOLTON.

The "Perfectum" will be exhibited in the Parkes Museum, London, and at the Glasgow Exhibition.

Architects can have a Model Free of Cost on application.

See Illustrated Advertisement first week in each month.

GREGSON'S  
PLAIN ROUND CLIP,  
From 7d. each.

For projecting Pipes without Ears by means of a Galvanised Bolt. All hang on the nails and save the walls.

**GILBERT WOOD & CO.,**  
175 STRAND, LONDON, W.C.

know to what extent electricity could be carried; but he felt confident that the electric light was to be the light of the future, though in other directions there would be a large field for the use of gas. The company also took over from the Whitehall Company the extensive and valuable property, the Waterloo Bridge Wharf, which was admirably adapted for supplying the whole of the Strand district, and which could take the machinery required for working 150,000 lamps. That, he thought, would be, perhaps, the largest installation on their system. Before another year was passed he hoped that that installation would be in active operation. He hoped that the great experiment now being tried by the Grosvenor Gallery combination would prove successful, for, if so, he believed it would be a very remarkable step in electric lighting progress. In the case of their own company, however, they had thought it wiser not to put all their eggs in one basket, and had so placed their different installations that they could work them collectively or separately. Since August the directors had secured several other sites for works, among others two for lighting the City proper and the Marylebone district. With reference to the Strand district, they had secured a monopoly of the lighting of the new Salisbury estate, consisting of Salisbury and Cecil Streets. They had given notice of a Bill in Parliament for powers to carry on the works for St. James's, Westminster, St. Martin's-in-the-Fields, and Waterloo Bridge. That would include the ground covered by the provisional order obtained last summer, but not confirmed by Parliament. Notices had also been given for four provisional orders for supplying mid London, north London, south London, and west London. Altogether they considered the prospects of the company very satisfactory.

## PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Cassell, Consulting Patent Agents, 43 Southampton Buildings, Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

## APPLICATIONS FOR PATENTS.

18269. James Lisle and Ben Lisle, for "An improved draught and weather excluder for the bottom of doors, windows, &c." December 14, 1888.

18294. Edwin Sydney Strange and John Clayton Austen,

for "Improvements in the construction of smoke extractors, exhausters, ventilators, and the like." December 14, 1888.

18297. Ebenezer Brown Hill, for "Improvements in gas brackets." December 14, 1888.

18308. John Henry Abel, for "A new and improved automatic door closer." December 15, 1888.

18333. Florence Welding, for "A novelty in house decorations." December 15, 1888.

18346. Richard Rowbotham, for "Improvements in ash-pans and dust-preventers for kitchen and other fireplaces." December 15, 1888.

18351. James Roach, for "An improved buddle for mining purposes." (Complete specification.) December 15, 1888.

18352. John Tate Williamson, for "An improved fastener for shaky windows." December 15, 1888.

18376. William Watson, for "Attaching the cords to window sashes, so that the cords can be attached and renewed, without removing the sashes from the frames." December 17, 1888.

18386. Joseph Cavargna, for "Improvements in charcoal-box irons in downward draught and grate thereof." December 17, 1888.

18388. Strethill Harry Wright and Richard Bate, for "Improvements in or connected with flushing cisterns for water-closets and urinals, also applicable to other purposes where it is required to regulate the supply of liquids, and then discharge a given quantity." December 17, 1888.

18443. Gilbert Samuel Tonks, for "Improvements in the construction of bakers' ovens." (Complete specification.) December 18, 1888.

18463. Joseph Hall, for "Improvements in kitchen-range bars." December 18, 1888.

18482. George Schuck and Henry Rudolf Schuck, for "Improvements in artificial stone." December 18, 1888.

18568. Charles Henry Beloe, for "Improvements in and connected with the purification of sewage and other foul liquids." December 19, 1888.

18570. John Baptiste Papier, for "Curing smoky chimneys and ventilating rooms and other similar places." December 19, 1888.

18606. David Howarth, for "Loose lip-and-basin trap, with pipe for bath, lavatory, or sink." December 20, 1888.

18607. John William Cooper, for "An ash-pan or dust-box for kitchen fire-ranges or other similar purposes." (Complete specification.) December 20, 1888.

YOCKNEY & CO. (Sole Owners),

CORSHAM DOWN QUARRY,

CORSHAM, WILTS.

Note.—No Connection with the other BATH STONE FIRMS.

18624. James Gray Connell and John Gordon, for "Improvements in valve apparatus for water-closet and other apparatus." December 20, 1888.

PROVISIONAL SPECIFICATIONS ACCEPTED.

14158. David Clohsey, for "Improved means for under-cutting or forming dowel-holes in wood, stone, metal, or other material." October 2, 1888.

15745. John Porter, for "Improvements in tops for chimneys and the like." November 1, 1888.

15793. William Logan, for "Improvements in and appertaining to portable and other hearths, and in blast apparatus therefor." November 1, 1888.

16011. James Shepherd, for "Improvements in treads for stairs, steps, landings, and floors." November 6, 1888.

16045. Walter Thomson, for "Improvements in door-knobs and in affixing the same to their spindles." November 6, 1888.

16185. Arthur James Smith, for "An improved apparatus for dressing white lead and other colours." November 8, 1888.

16210. Melchior Szabo, for "Improvements in kitchen-ranges." November 8, 1888.

16468. Oliver Phalps, for "Improvements in skylights and ventilators, applicable also to compass binnacles for use on board ship." November 13, 1888.

16708. Samuel Richardson, for "Improvements in revolving brush machine for street-scavenging purposes." Nov. 17, 1888.

16811. William Joy, for "Improvements in apparatus for crushing and grinding cement, clinker, and similar matters, and for separating the finer from the coarser particles of ground cement, clinker, and similar materials." November 19, 1888.

17052. Joseph Laming, for "An improved cap or cowl for preventing down-draughts in chimneys and ventilating-shafts and analogous purposes." November 23, 1888.

17257. William Cussaus, for "Improvements in colouring and ornamenting Portland cement for the manufacture of imitation, grained or figured marble mosaics, ornamental slabs, tiles and other forms, either in plain or in mixed colours." November 27, 1888.

17446. George Humphrey, for "Improvements in weather bars or thresholds for doorways and doorsteps." November 30, 1888.

17525. Burton Richard Phillipson, for "Improvements in the ventilation of drains and soil-pipes." December 1, 1888.

17665. John Lander, for "Improved apparatus for clearing drains." December 4, 1888.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is hereby given, that all persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the date of the official *Journal*, give notice at the Patent Office on the prescribed form of such opposition.

17674. Frank Porter Pyne and Ralph Hore Pyne, for "Improved closet-pan." December 23, 1887.

739. Benjamin Stuart and Harry Hanwell, for "Improvements in roofing tiles and hanging tiles." January 17, 1888.

1764. Reginald Stanley, for "Improvements in ovens or kilns for burning bricks, tiles and other articles." February 6, 1888.

1980. Matthew Henry Heys, for "Improvements in and relating to the manufacture of lime and of natural and artificial cements." February 9, 1888.

2380. David Williamson and Robert Williamson, for "Improvements in or relating to the warming and ventilating of rooms, buildings, and the like." February 17, 1888.

2803. John Brimton and Lewis Griffiths, for "Improvements in the manufacture of artificial stone." February 24, 1888.

5667. John William Anger, for "Improvements in fanlights and ventilator openers." April 17, 1888.

PATENTS SEALED, DECEMBER 21, 1888.

16877. Hiram Stevens Maxim, for "Intermittent water discharge, applicable to the washing out of drains, water-closets, and to similar purposes." December 8, 1887.

2199. Francis Joseph James Gibbons, for "Improvements in hanging centre plates for fanlights, applicable also to other analogous purposes." February 14, 1888.

2886. Francis Joseph James Gibbons, for "An improvement in sash pulleys for windows, applicable also to pulleys for other purposes." February 27, 1888.

10913. George Davis, for "Improvements in drain traps." July 28, 1888.

12589. Henry William Joseph White, for "Improvements in windows and other fasteners, specially applicable to sashes, basements, doors, and for similar purposes." Sept. 1, 1888.

TO INVENTORS.—Patents for Inventions, Trade-marks, and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & CASSELL, Patent Agents, 43 Southampton Buildings, Chancery Lane.

## THE "WEAVER," THE "IMPERIAL," & THE "OXFORD" Patent Sanitary & Ventilating Appliances.

The "WEAVER" IMPROVED VENTILATING DRAIN TRAP, from 6s. 6d.

The INTERCEPTOR SELF-CLEANING TRAP, for Vertical or Horizontal (or both combined) Rain-water or Waste Pipes, White Glaze, from 7s. 6d.

YARD TRAP, White Glaze, Cast-Iron Frame and Grid, 5s.

INTERCEPTOR TRAP, for Waste and Rain-water Pipes, 7s. 6d. and 10s. 6d.

The "IMPERIAL" ROOF, SOIL-PIPE, and CHIMNEY EXHAUST VENTILATORS, from 12s. 6d.

The "OXFORD" CLOSET, 10s. 6d. Tank and Fall-Pipe 20s.

STEEL SINK, from 6s. 6d.

VALVE or PAN CLOSET VENTILATOR ATTACHMENT, 15s.

SINK TRAP, with Union, 10s. 6d.

COMBINATION CLOSET, 15s. and 20s.

The COTTAGE CLOSET, 10s. 6d. Tank and Fall-Pipe, 20s.

NOTE.—All Closets are fitted with the "Weaver" Flush Fan, with cascade action, giving noiseless and yet greater flushing and cleansing power than any other Closet. The "Weaver" Flush Fan, being adaptable to ALL KINDS of Closets, licences may be granted to manufacturers. Traps up to 3 in. With a supply of the Iodate Sanitary Salt, these Closets are odourless. Lead Closet Trap, for boarded floors, 7s. 6d. and 10s. 6d. Ball Valves to Flush Tanks, for quick filling under low pressure, 4-in. 2s. 6d.; 3-in. 3s. 6d., and Stop Cock, 3s. 6d. ILLUSTRATED LIST. Also "Instructions in Sanitary Construction" (Domestic edition abbreviated), and Memorandum on House Sanitation, and the Law of Landlord and Tenant thereon. By E. WEAVER, C.E., F.C.S., Sanitary Surveyor, free by post.

THE DOMESTIC ENGINEERING AND SANITARY APPLIANCES COMPANY, 24 HIGH HOLBORN, LONDON, W.C.

FIFTEENTH YEAR OF PUBLICATION. NOW READY.

## "THE ARCHITECT'S DIARY" FOR 1889.

Specially prepared for the use of ARCHITECTS, SURVEYORS, and ENGINEERS.

These Publications contain not only the usual Diary, ruled and printed to a particular form, specially adapted for professional use, but, in addition, an Index, a Note-Book, a Rent and Insurance Register, a Cash Book, and a Ledger, with all the usual diary information, and much special matter referring to the various Architects' and Engineers' Associations; a digest of all the Acts passed last Session; contain also cases decided in the Superior Courts of Justice during the legal year, from November 1887 to August 1888, of interest to the Profession; complete list of Metropolitan Surveyors and Districts, with Official and Private Address; Alphabetical Index to the Practical Statutes, Stamp Duties &c., the whole forming in ONE VOLUME A COMPLETE SET of BOOKS for the YEAR. The Editions are—  
No. 12.—One page to a day, size 8½ in. by 5 in., cloth, gilt, 4/6. | No. 13.—Two pages a day, size 8½ in. by 5 in., cloth, gilt, 5/6.

## "THE BUILDER'S DIARY" FOR 1889.

Specially prepared for the use of BUILDERS and CONTRACTORS.

No. 11.—Two days on a page, ruled and printed to a special pattern; also contains Bill Register, Note Book, Rent, Insurance, and Mortgage Register, Cash Book, Ledger and 130 pages of Tables of great value to all engaged in the Building Trades, in all 460 pages, size 8½ by 5, bound, whole cloth, gilt. Indexed, and pagged to end of Diary. Price 4s. 6d.

"For use in the office of Architects and Builders they are better fitted than any diaries with which we are acquainted."—*The Architect*.

"Messrs. Hudson & Kearns's Diaries need no recommendation save a trial."—*The British Architect*.

"The novel and valuable feature of these Diaries is that each volume forms in itself a complete set of books for the year."—*The Builder*.

"We have used them ourselves throughout the year with much satisfaction, and are glad now to draw attention to the new batch sent us."—*The Building News*.

"The Diaries published by Messrs. Hudson & Kearns are quite unrivalled for convenience and comprehensiveness."—*Building World*.

"These Diaries may be said to have become the Diaries for the professions for which they are issued."—*Illustrated Carpenter and Builder*.

Sole Publishers, HUDSON & KEARNS, 83 Southwark Street, London.

f. rents. Free estimates given on application.

KARL SAELOW, 27 North Street, Knightsbridge.

**HOUSE, HOTEL & CLUB  
FURNISHERS  
AND  
DECORATORS.**

# THE "THOMAS" LAMP.

Lighting Power with  
ordinary London Sixteen-  
Candle Gas, from tests  
taken by Professor Wm.  
Foster, M.A., L.R.C.S.

No.	
10.	11.4 Candle-power per foot.
11.	12.5 " "
12.	12.5 " "

These Lamps are made in three  
sizes, Nos. 10, 11, 12.

These Lamps can be obtained through Gasfitters, Ironmongers and  
Merchants. Foreign Orders through Merchants only.

The advantages of this Patent  
over other existing Lamps  
are:—

Small consumption of Gas  
with great Illuminating power.

No possibility of the Burner  
corroding or getting out of  
order, as is the case with other  
generative gas lamps.

The Lamp can be fitted by  
any gasfitter. No fine per-  
forated metal, gauze, or other  
obstructions are used in this  
Patent, as in other lamps which  
are liable to become choked  
through imperfect combustion,  
rendering the lamps smoky and  
useless.

FOR FURTHER PARTICULARS, APPLY TO

**Ridsdale's Railway Lamp & Lighting Company, Ltd.,**  
**55 & 56 MINORIES, LONDON, E.C.**
